The following gentlemen were present:—Thomas Paget, Esq., Leicester; Dr. Barclay, Leicester; Charles Bowman, Esq., Leicester; Dr. Goode, Derby; W. Cantrell, Esq., Wirksworth; Dr. Smyth, Bingham; John Higginbottom, Esq.; B. Eddison, Esq.; A. Darby, Esq.; J. C. L. Marsh, Esq.; Dr. Sloane; Dr. H. Payne; J. S. Alderson, Esq.; G. E. Stanger, Esq.; H. Higginbottom, Esq.; J. N. Thompson, Esq.; J. White, Esq.; etc.

MEDICAL REFORM BILL.

It was proposed by THOMAS PAGET, Esq., of Leicester; and seconded by WILLIAM CANTRELL, Esq., of Wirksworth, "That the Midland Branch of the Provincial Medical and Surgical As-

sociation respectfully request the Members of Parliament for the Midland Counties favourably to consider the New Medical Bill in Parliament; and, if possible, to accompany the deputation of the Association which is appointed to wait upon Lord Palmerston, at his residence in Carlton Gardens, on Thursday, the 17th inst., at 12 o'clock, for the purpose of submitting to his lordship the said bill."

This resolution was unanimously adopted; and it was then determined that a copy of it should be sent to each of the Members of Parliament for the district.

INCOME-TAX.

It was moved by Mr. EDDISON, of Nottingham; seconded by Dr. GOODE, of Derby, and resolved, "That a petition to Parliament, relative to the unjust bearing of the Income-Tax, be prepared, and sent for signature to the different parts of the Midland district."

NEW MEMBERS.

Dr. BARCLAY, of Leicester, proposed that the following twenty-eight new members of the Association, be elected members of the Midland Branch:—Dr. Shaw; A. Cooper, Esq., T. W. Benfield, Esq., W. May, Esq., J. H. Stallard, Esq., W. Derington, Esq., John Buck, Esq., and Dr. Irwin, all of Leicester; W. J. Franks, Esq., Billesdon; E. McIlree, Esq., Claybrook; T. Spencer, Esq., Earl Shilton; T. W. Paterson, Esq., Ibstock; Dr. Eddowes, Loughborough; S. Hunt, Esq., Loughborough; F. Stevenson, Esq., Loughborough; J. Gill, Esq., Syston; H. Nuttall, Esq., M.D., Syston; J. C. Robinson, Esq., Syston; J. Hunt, Esq., Thornby; J. Keal, Esq., Melton Mowbray; J. B. Bradshaw, Esq., Quorn; R. Wing, Esq., Burrow-on-the-Hill; T. S. Ludlow, Esq., Sapcote; J. M. Fewkes, Esq., Glem Magna; J. H. Spencer, Esq., Hallaton; W. Orton, Esq., Narborough; H. Hudson, Esq., Somerby; and S. Wright, Esq., Mount Sorrel.

Mr. PAGET seconded this motion, which was carried unanimously.

ERYSIPELAS.

Mr. HIGGINBOTTOM read a paper on "Erysipelas as a Local Disease", which we have received, and hope to be able to publish in an early number.

After an interesting discussion on Mr. Higginbottom's paper, in which Mr. Paget, Mr. Eddison, Dr. Goode, Mr. Cantrell, and others, took part, a vote of thanks to the author was moved by Mr. Eddison, seconded by Mr. Paget, and carried unanimously.

MEDICAL ETHICS.

This subject was introduced by Dr. GOODE, of Derby, who read the Rules of the Medico-Ethical Societies of Manchester and Huddersfield; and suggested that the opinion of the meeting should be taken as to the propriety of adopting a code of ethical rules for the Midland Counties Branch.

After remarks by Dr. Barclay and Mr. Paget, of Leicester; Mr. Stanger, Mr. Eddison, and Mr. Higginbottom, of Nottingham; and Dr. Smyth, of Bingham, all of whom agreed as to the absence of any necessity for the introduction of such rules in this neighbourhood,—

Dr. BARCLAY, of Leicester, moved, and Mr. DARBY, of Nottingham, seconded, "That the Midland Branch of the Provincial Medical and Surgical Association decline to adopt any code of ethical rules, as unnecessary in this district." This resolution was carried.

NEXT ANNUAL MEETING OF THE BRANCH.

The next meeting (the Annual Meeting of the Branch) was appointed to take place at Leicester, on Thursday, the 10th of June, under the presidency of Thomas Paget, Esq.

A vote of thanks to Dr. WILLIAMS, for his able conduct in the chair, was proposed by Mr. STANGER, and seconded by Mr. PAGET, and carried unanimously.

METROPOLITAN COUNTIES BRANCH.

A Special Meeting was held on Tuesday, at 4 P.M., at 87, Great Queen Street, Lincoln's Inn Fields: Dr. FORBES, the President, in the Chair.

MEETINGS OF THE BRANCH.

Mr. RICHARDSON (of Mortlake) asked whether it was intended that there should be more than one General Meeting of the Branch in the course of each year? He thought that Quarterly Meetings of the Branch would be most desirable, as by this means the members would be enabled to express to each other their opinions regarding the state and prospects of the profession, and to read and discuss papers connected with the advancement of medical science.

The PRESIDENT thought that as this meeting was called for two special purposes, Mr. Richardson's remarks, though important, were scarcely in order.

Dr. CORMACK quite agreed with what Mr. Richardson had said; but, after what had fallen from the chair, he should only now observe that it was his intention, at the next Council Meeting, to urge the propriety of holding Quarterly Meetings of the Branch.

INCOME TAX.

Dr. CORMACK said, that the propriety or impropriety of an income-tax was hardly a question for a medical society to give an opinion upon; and it was a question of general politics, with which he would not trouble the meeting. The political bias of the day was in favour of direct taxation, and it was certain that the income-tax would be re-imposed, and probably become permanent. A more just distribution of the tax was therefore the point upon which it behoved the medical profession to concentrate its energies. He therefore moved—

"That inasmuch as the present mode of assessing the Income-tax is peculiarly severe upon all who depend upon temporary or life incomes; and as it presses with special injustice upon members of the medical profession, from their incomes being not only terminable by death, but even contingent upon daily health; it is the duty of the Metropolitan Counties' Branch of the Provincial Medical and Surgical Association to petition both Houses of Parliament in favour of a more equitable distribution of the said income-tax, should it be again imposed."

Dr. ARCHIBALD DOUGLAS seconded the motion, which was put by the Chairman, and carried unanimously.

Dr. SIBSON moved: "That the following petition be adopted as the petition of the Metropolitan Counties' Branch of the Provincial Medical and Surgical Association, be signed by the Members, and then forwarded by the Secretary to Sir Benjamin Hall, M.P., for presentation to the House of Commons, and to Lord Brougham, for presentation to the House of Lords:—

"The Humble Petition of the undersigned Members of the Metropolitan Counties' Branch of the Provincial Medical and Surgical Association, sheweth—

"That your petitioners have, for the most part, no other income than that derived from their professional exertions.

"That their income so derived is uncertain and precarious, necessarily ceasing under illness, in advanced life, and at death.

"That considering their position in society, the exercise of their profession requires them to maintain unusually expensive establishments, involving considerable direct taxation.

"That your petitioners are, for the most part, married men, with families, for whose education and present and future support they have to provide by these uncertain and precarious incomes, under the contingencies of illness, advanced age, and death.

"That your petitioners represent, moreover, that their lives are shorter, they are more liable to accidents and disease, frequently communicated by their patients; and that the decline of their professional incomes is earlier than in any other profession.

"That for the above reasons and others that might be adduced, the capitalized value of the precarious income of a medical man is not only below that of an income derived from a permanent annuity, but is also even considerably below the value of a received life annuity, which itself is scarcely half the value of a permanent annuity.

"That for the above reasons, your petitioners feel it a great grievance, and cannot but consider it most unjust, that their professional incomes, thus precarious, should be taxed at the same rate as incomes derived from realized property.

"And your petitioners therefore humbly pray that it may please your Honourable House so to deal with the income-tax, if it be indispensable to retain it, that its pressure on medical men and others, whose incomes are temporary and uncertain, may be equitably adjusted in proportion to their real value.

"And your petitioners will ever pray, etc."

Mr. CARTER (of Hadley) seconded the motion.

Dr. O'CONNOR urged the necessity of appointing a deputation to wait upon the Chancellor of the Exchequer. It was of the first importance to communicate with him, and that too as early as possible.

The PRESIDENT thought it doubtful whether such a proposal could be considered, as it was not mentioned in the advertisement calling the meeting.

Mr. RICHARDSON supported Dr. O'Connor's views.

Dr. SIBSON did the same.

The CHAIRMAN then put the question, Whether it was the opinion of this meeting that Dr. O'Connor's resolution could be entertained?

The meeting, by a majority of votes, decided that it could be entertained.

Dr. O'CONNOR eventually withdrew his original resolution, and proposed the following modification of it:—

"That the following gentlemen do form a committee, to co-operate with the Income-Tax Committee of the parent Association, and to suggest the propriety of appointing a deputation from the Association to wait on the Chancellor of the Exchequer on the subject of the Income-Tax.

Dr. SIBSON,
Dr. POWELL,
Dr. GRIFFITH,

Dr. O'CONNOR,
Mr. ANCELL,
Mr. RICHARDSON,

With the PRESIDENT and SECRETARY."

Dr. GRIFFITH seconded this resolution, which was carried unanimously.

Dr. SIBSON moved, that Dr. Cormack, being a member of the Income-Tax Committee of the Parent Association, should be requested without delay to communicate with that body. This was agreed to.

Dr. CORMACK asked if he might, in writing to Dr. Malden, of Worcester, the Chairman of the Income-Tax Committee of the Parent Association, state, that it was the unanimous opinion of this meeting that a numerous deputation of the Parent Association ought, with as little delay as possible, to seek an interview with the Chancellor of the Exchequer, to plead the cause of the profession?

The PRESIDENT said, that he believed that Dr. Cormack rightly stated the feeling of the meeting. (Hear, hear.)

Mr. RICHARDSON moved, "That the sub-committee now appointed be instructed to wait upon Lord Brougham and Sir B. Hall, to request them to present the petitions of the Branch to both Houses of Parliament."

Dr. HOWARD seconded the motion, which was unanimously carried.

PARLIAMENTARY REPRESENTATION OF THE UNIVERSITY OF LONDON.

Dr. SNOW BECK, in an eloquent speech, introduced this subject. He said that it was very far from his wish, in making the motion with which he intended to conclude, to restrict the privilege of parliamentary representation to the University of London. He was in favour of extending it to all unrepresented universities. He thought, however, that if the privilege were given to the University of London, a good beginning would be made, and other universities could then demand similar rights. He had no wish to represent the question as identical with that of the parliamentary representation of the medical profession; but he must say, that such a constituency as the University of London would represent the profession better than it had ever yet been represented; and, as the medical graduates increased in number, the amount of medical representation obtained through the university constituency would be likewise increased. He concluded by moving the following resolution:—

"That this Society views with pleasure the present movement in the University of London, having for its object the extension of the parliamentary representation to the educated classes; and considers it expedient to support this movement by forwarding a petition to the House of Commons, praying that the franchise may be bestowed on the London University."

Dr. RISDON BENNETT had read with surprise, as part of the advertisement calling this meeting, the announcement of the subject which had been brought forward by Dr. Snow Beck, as he conceived it to be one which was not within the limits of the Provincial Medical and Surgical Association. The question was purely a political one; and, as such, he deprecated its being discussed at any meeting of this Branch. If, however, he were asked to enter upon the merits of the question, he would say that a medical society ought not, as a medical society, to support the movement now being made by the London University, as it tended to make Parliament and the public suppose that granting representation to the University of London was equivalent to granting representation, to a certain extent, to the medical profession, which was very far from the truth. Parliamentary representation was one of the greatest desiderata of the medical profession; and no more effectual means could be taken to prejudice that question, than medical societies taking up the claims of the University of London as a question in which they had a peculiar interest. In any capacity except as

a member of a medical society, he could have no objection to sign Dr. Snow Beck's petition: but he wished to guard against damaging the question of medical representation in Parliament. And, as regarded the Universities, he must say that there were other unrepresented Universities which had a much stronger claim to have members of Parliament, both from the greater number of their graduates, and their more ancient and influential position.

Dr. SIBSON. Name them.

Dr. RISDON BENNETT said that he had no objection to do so: and he would mention Edinburgh and Glasgow. Believing that the cause of medical representation would be endangered by medical bodies taking the course recommended by Dr. Snow Beck, he would always oppose such a course: but, upon the present occasion, he specially objected to the motion on account of its exclusively political bearing.

Dr. SIBSON seconded Dr. Snow Beck's motion. He said, in reply to Dr. Bennett, that as more than one third of the graduates of the University of London were medical men, the question must be regarded as one which closely concerned the profession. To obtain the elective franchise for the University of London, would, in his opinion, be the getting in of the wedge, and be the beginning of a concession of similar privileges to all literary, scientific, and medical institutions.

Dr. POWELL, as an old graduate of the University of London, warmly supported Dr. Snow Beck's resolution.

Dr. CORMACK thought that the legal question mooted by Dr. Bennett was that which was immediately before the meeting; and that the simplest way of bringing the matter to an issue, was to decide whether Dr. Beck's proposition could be entertained without violating the spirit of the ninth law of the Branch, which was as follows:—"That all subjects connected with medical science or the profession be admissible for discussion." Supposing, however, that that law might be interpreted in its widest sense, he would still say, that, as a matter of policy, it was wrong for this Branch, or any Branch of the Provincial Medical and Surgical Association, at the present crisis, to take up the question of the parliamentary representation of the London University. As Dr. Bennett had stated, nothing could more endanger the claims of the profession to be represented. He entirely differed from Dr. Sibson, and denied that the questions of university and medical representation were in any way similar; and he thought that if medical men were at present to agitate for the parliamentary representation of the University of London, and that was to be obtained, they would be told that they had got the kind of parliamentary representation which they had first asked, and had therefore most desired.

Dr. RISDON BENNETT said, that to bring the question of order to a decision, he would propose the following amendment: "That the question of granting the elective franchise to the University of London, being essentially a political question, does not legitimately come under the consideration of the Provincial Medical and Surgical Association."

Dr. COGSWELL seconded this amendment. He observed that the parliamentary representatives of the Universities of Oxford and Cambridge rendered no service to the medical profession; and believed that the same would be the case with regard to any members which might be chosen by the University of London. He concurred with the remarks of Dr. Bennett and Dr. Cormack, and concluded by asking Dr. Beck or Dr. Sibson whether it was intended to secure to the University of London medical representation?

Dr. SIBSON again defended Dr. Beck's resolutions; and in answer to Dr. Cogswell's question, said that what the graduates of the London University wished to obtain, was certainly not exclusive medical representation, but general university representation, which would include medical representation.

Mr. RICHARDSON supported Dr. Beck's resolution. He thought that, if the profession would in any way be benefited by the franchise being given to the graduates of London, this meeting ought not only to entertain the question, but to give its best help. The representatives of such a constituency as the London University would undoubtedly be much influenced by the medical body which it contained; and as to the other question which had been alluded to—the claims of other universities—he thought that the present movement should not be regarded by them with jealousy, but be felt as a spur to similar exertions.

Dr. DOUGLAS maintained that the representation of the University of London was a purely political consideration, connected with a general redistribution of the elective franchise; and, as it was a political question, and therefore foreign to the objects of the Association, he would support Dr. Bennett's amendment.

Dr. SNOW BECK replied to the observations of the previous speakers.

The PRESIDENT put the amendment to the meeting, when it was found that an equal number voted for it and against it; whereupon he stated, that it lay with him to give the casting vote; and that in doing so, he felt bound to state, that he did not regard the question as a political one. It was not nearly so political as the income-tax question. When that was originally mooted in the Council, he had felt so strongly that petitioning in connexion with the income-tax was an improper interference with politics, that he had strenuously opposed it, though he had ultimately perceived that it might legitimately be entertained as a professional question by the Branch. After strongly deprecating the discussion of political questions at the meetings of the Metropolitan Counties Branch, he concluded by giving his vote against the amendment; which was then declared to be lost.

The PRESIDENT then put the original motion, whereupon Dr. CORMACK, after asking whether he was in order in offering another amendment proposed (with permission of the Chair), that, in place of "*London University*", the last two words of Dr. Snow Beck's motion, the words "*unrepresented universities*" should be substituted. He thought, from the tenor of the speeches of Dr. Snow Beck and Dr. Sibson, that they would not object to this proposition; and he hoped that it would meet with the unanimous concurrence of the meeting.

Dr. GRIFFITH said that, from the terms of the advertisement summoning the meeting, he did not think that such an amendment could be received. They were there specially assembled to consider the claims of the University of London, and of no other university.

After some conversation, Dr. Cormack withdrew his amendment.

The original motion was then put. Upon a division, the same result was obtained as when Dr. Bennett's amendment was put; and the motion was declared to be carried by the Chairman's casting vote.

Dr. SNOW BECK read the petition suggested for adoption.

It was moved by Mr. CARTER, seconded by Mr. RICHARDSON, and carried by the casting vote of the Chairman, that the petition read by Dr. Snow Beck be adopted.

After a vote of thanks to the Chairman, the meeting broke up.

[The Income-Tax Petition lies for signature at the office of the JOURNAL, 37, Great Queen Street.]

EDITOR'S LETTER BOX.

THE LATE INQUEST AT TODDINGTON.

LETTER FROM PATRICK BENSON, Esq., to the Editor.

SIR,—I think the time has now arrived, when I can with propriety enter into an explanation of the evidence I gave, as well as the part I have been compelled to take, in the late proceeding against Mr. Hicks, for manslaughter.

In the first place, I much regret, with Mr. Hicks, as well as with many of his friends, that his case did not come on for trial. Then I could, in open court, have vindicated and explained my conduct, without in the least injuring the cause of Mr. Hicks.

As I have already stated in my letter of the 18th ult., I was called to see the deceased child a few hours before its death, and was then informed, by its mother, that Mr. Hicks had been attending the child, and that he told her the bone was broken, and had treated it accordingly. In reply to a question, I said that there was no bone broken; and in consequence of that opinion, I was requested, by a relative of the deceased, to make an examination of the part, for the purpose of ascertaining whether the bone was broken or not. This I did in conjunction with Mr. Tomson. That was the only examination which ever was made; and it was made only for the purpose of satisfying the friends, and for no ulterior object, nor from any vindictive feeling, either on my part, or on the part of the relatives of the deceased; for I believe that the proceedings against Mr. Hicks had been instituted without their knowledge or consent. I then recommended the child to be buried, and gave no opinion as to the cause of death, nor did I hear any more of the affair until I was summoned, a month afterwards, to attend the inquest.

Who was the cause of instituting that investigation, I must leave Mr. Hicks to discover. At the inquest, and after hearing the evidence of the mother and other witnesses, I was asked, by the Coroner, what, in my opinion, was the cause of death?

replied, that the immediate cause of death was effusion or congestion of the brain, caused, in my opinion, by the shock which the nervous system received from the long-continued pain the child suffered from the abscess. And I added, as another cause, that it was possible that absorption of matter might have taken place, producing a similar result, and that this of course might have taken place quite independent of any pressure.

In answer to the next question, relative to the bandages, I replied that of course the bandages, by their pressure, increased and kept up the pain. And I now ask, what other opinion could I have given as to the cause of death, in the absence of any other apparent cause? for you will be pleased to bear in mind, that there had been no *post mortem* examination made, except of the affected part. I never, however, meant to convey by that opinion, nor did I think that the jury could infer, that it was Mr. Hicks's treatment that had caused the death of the child. I was not asked a question by the coroner that would have elicited a favourable reply; and, unfortunately, Mr. Hicks had no legal adviser to cross-examine the witnesses. I strongly urged on Mr. Hicks, jun., the expediency of procuring one, but he refused. Subsequently, seeing the impression apparently made on the jury—not by my evidence, but by that of the mother—I urged upon Mr. Hicks the propriety of his going home, that, in case an adverse verdict should be returned against him, he might get out of the way for a few days, until he could procure bail. For this humane and charitable advice, given to an old man bordering on seventy years of age, the coroner expressed his regret to some of my friends, and appeared much mortified that he had not been made acquainted with my advice to Mr. Hicks sooner, for he said that if he had, he would have certainly sent me with Mr. Hicks to prison, as an accessory after the fact, in aiding and abetting in that awful case of manslaughter.

Up to this period, I had never heard of an injury which, it appears, the child had received from a fall, nor of a dislocation of the head of the fibula, for which it now appears Mr. Hicks had treated the child; and not for a fracture, as had been represented to me, nor did I hear of the injury or of the dislocation until after Mr. Hicks had been committed to prison. Now, I cannot say whether or not there had been a dislocation. Not having any idea that I should be called upon to give evidence before a jury, I did not make that particular examination which I otherwise should have done; consequently, a dislocation of the head of the fibula might have escaped my notice, not expecting to find such an injury. Admitting, then, this to be the case, Mr. Hicks's treatment was perfectly justifiable and correct. I presume that he did not anticipate the formation of an abscess, which might have been produced either by the accident, or by a general bad state of health.

It is a matter of surprise why Mr. Hicks did not make known the above circumstances to the jury; but the only explanation is, that Mr. Hicks is very deaf, and I believe did not hear one word of what was said in the inquest-room. Mr. Hicks, jun., being a very young man, was so bewildered by the unexpected charge brought against his father, that he had scarcely power to make any explanation, or offer any observations.

In conclusion, I must a second time repel, as wholly untrue, the statement that I had been actuated by any unkind or vindictive feeling towards Mr. Hicks, in the part I was compelled to take in that inquest. Mr. Hicks has never injured me, nor I him purposely or wilfully; and all persons (whether medical or non-medical) who know me, are aware that I am wholly incapable of such base and dishonourable proceedings.

Begging you to insert this in your next number,

I am, etc.,

PATRICK BENSON.

Laton, Bedfordshire, March 14th, 1853.

PYÆMIA.

LETTER FROM HENRY LEE, Esq., TO THE EDITOR.

SIR,—MR. GAMGEE, an able writer in the ASSOCIATION MEDICAL JOURNAL of the 4th inst., has noticed my work on the *Origin of Inflammation of Veins*. He observes, "To argue, as Mr. Lee does, from the fact that, out of the body, blood coagulates round pus, therefore such a combination cannot circulate in the living body, is about as warrantable as it would be to predicate, from the observation that pure blood coagulates (in an unusual manner) in a basin, that it therefore cannot remain fluid in the ventricles of the heart." The opportunity was afforded me only yesterday of inspecting a preparation from a case, in which suppuration, to a limited extent, had taken place

in the pericardium; and in which the auricle and ventricle of the right side of the heart both contained a firm decolourised mass of fibrin. That in the ventricle weighed upwards of three drachms, was firmly adherent, and terminated in a long, slender process, which extended several inches into the pulmonary artery. Analogous cases are not very uncommon; and some such have been published in the work referred to. You will, therefore, be prepared to admit, to a certain extent, the truth of the above criticism. The only modification required, is the substitution for "pure blood", of "vitiated blood", to which alone my remarks applied.

I am, etc.,

HENRY LEE.

13, Dover Street, Piccadilly, March 11th, 1853.

EDITORIAL APPROPRIATION WITHOUT ACKNOWLEDGMENT OF THE REAL SOURCE.

LETTER FROM THE EDITOR OF THE DUBLIN QUARTERLY JOURNAL OF MEDICAL SCIENCE TO THE EDITOR.

SIR,—In the ASSOCIATION MEDICAL JOURNAL for February 18th, a translation of a paper on the "Iodide of Sodium", from an Italian journal, is stated to be abridged from the *Chemist*. This translation was made originally for my journal, and was published in the number for November 1852: it was thence quoted without acknowledgment by the Editor of the *Chemist*, I suppose, through inadvertence. You could not, therefore, have been aware of this fact.

I shall feel obliged by the insertion of this note in your Journal.

I am, etc.,

THE EDITOR OF THE DUBLIN QUARTERLY JOURNAL OF MEDICAL SCIENCE.

[In accordance with our universal plan, we gave the immediate source of our information. As to unacknowledged appropriation, we might say a good deal, as we are often amused to see the impudent and clumsy way in which our own pages are pilfered from. Our critical remarks being often blended with our abstracts are frequently cited as if translated from a foreign journal which we may have incidentally mentioned.—EDITOR.]

NEWS AND TOPICS OF THE DAY.

HOSPITAL FOR SEAMEN. During the past year, 2,316 patients were admitted on board the DREADNOUGHT, and those supplied with medical assistance and stores, as out-patients, amounted to 1554, making a total of 3870. £136 was received by the subscription-boxes under the care of the shipping-masters, which was contributed chiefly by seamen. The society received three legacies during the year—£300 from Mr. Benjamin Hill, £100 from Mr. Boucher, and £10 from Lady Colville. There were under cure, or convalescent, on the 31st of January last, 159. Of the 2316 admitted in the present year, there were discharged cured 1653, convalescent 181, relieved 88, not cured 10, deaths 75.

The patients of different nations received were in the following proportion:—Englishmen, 39,734; Scotchmen, 8199; Irishmen, 6035; Frenchmen, 249; Germans, 913; Russians, 871; Prussians, 1346; Dutchmen, 233; Danes, 907; Swedes and Norwegians, 2299; Italians, 639; Portuguese, 520; Spaniards, 313; East Indians, 1142; West Indians, 1167; British Americans, 918; United States, 1322; South Americans, 149; Africans, 391; Turks, 16; Greeks, 64; New Zealanders, 35; New South Wales, 36; South Sea Islanders, 226; Chinese, 42; born at sea, 137; total, 67,903.

In what service employed:—Her Majesty's navy, 3215; Hon. East India Company's service, 1798; merchant vessels of different nations, 62,890; total, 67,903.

The receipts for the year amounted to £8135:14:11; and the expenditure to £7716:11:4; leaving a balance of £419:3:7.

CHRIST'S HOSPITAL. The widow of the late Dr. Rice was, at the last meeting of the Governors, voted an annuity of £200.

ACADEMY OF MEDICINE IN PARIS. The following distinguished members of the medical profession were, on March 1st, elected foreign associates of the Academy of Medicine in Paris: M. Buffalini, of Florence; Dr. Valentine Mott, of New York; Professor A. Retzius, of Stockholm; Professor Riberi, of Turin; Professor J. Y. Simpson, of Edinburgh; M. Vlemminckx, of Brussels; and Dr. Warren, of Boston, America.

SCOTTISH UNIVERSITIES TESTS BILL.

[House of Commons, March 15.]

ON the motion of the Lord Advocate (MONCRIEFF), the House went into Committee on the subject of Religious Tests in the Scottish Universities.

The CHAIRMAN of the Committee moved that the Chairman be directed to move the House, that he be instructed to bring in a bill to regulate and modify the Tests to which the lay professors in the Scottish Universities are now subjected on admission to their chairs.

The motion was agreed to, and the bill was ordered to be brought in.

UNIVERSITY OF LONDON. DEPUTATION TO LORD ABERDEEN. On Wednesday the 16th inst., a deputation of the Graduates of the University of London, waited on Lord Aberdeen, prime Minister, to urge the claim of their University to be represented in Parliament. We understand that his Lordship expressed himself in general terms as favourable to the cause of University representation.

MEDICAL BENEVOLENT COLLEGE. The proceeds of the Bishop of London's advocacy of the claims of the college, on Sunday last, in Trinity Church, St. Marylebone, amounted to £85. His lordship in speaking of the casualties to which medical men are daily exposed, alluded to the lamented decease of the late Dr. Manson, mentioned in our last week's obituary. He truly said that such occurrences prove the duty which is imposed upon a Christian public, of aiding in alleviating the sorrows and privations consequent upon premature widowhood and orphanage.

THE ALLEGED HOMICIDE BY A DUBLIN PHYSICIAN. The bill for homicide against Dr. Banks, has been ignored by the grand jury, at the present criminal session. Dr. Banks, who was one of the physicians in ordinary to the Earl of Eglinton, during that nobleman's vice-royalty, struck a boy slightly with a cane for trespassing on his lands. The boy was soon afterwards seized with a disease in the neck which proved fatal. His friends attributed the boy's death to the blow; but the coroner's jury returned a verdict of "Natural Death". The family then preferred an indictment, which, as stated, was quashed by the grand jury.

THE FIRST PHYSICIAN OF THE EMPEROR OF THE FRENCH. Dr. CONNEAU has been all his life in the family of the present Emperor, and attended the latter's mother, Queen Hortensia. He was in London with Louis Napoleon, followed him in all his hazardous expeditions, and shared his captivity at Ham Castle. Dr. Conneau has given a proof of his good taste and sense of propriety, in declining to avail himself of the right he has just acquired as First Physician of the Emperor, to take his seat in the Academy of Medicine as Honorary President. This right is to be traced to the foundation of the Academy in 1820, when Portal, the first Physician to Louis XVIII, exerted himself so warmly in behalf of the society, that it was resolved to give him and his successors the honorary presidency of the Academy.

DISEASES AMONG THE BEDOUIN ARABS. Diseases are rare among them; and the epidemics, which rage in the cities, seldom reach their tents. The cholera, which has of late visited Mosul and Baghdad with fearful severity, has not yet struck the Bedouins; and they have frequently escaped the plague, when the settlements on the borders of the Desert have been nearly destroyed by it. The small-pox, however, occasionally makes great ravages among them, vaccination being still unknown to the Shammar; and intermittent fever prevails in the autumn, particularly when the tribes encamp near the marshes in Southern Mesopotamia. Rheumatism is not uncommon, and is treated, like most local complaints, with the actual cautery, a red-hot iron being applied to the part affected. Another cure for rheumatism consists in killing a sheep, and placing the patient in the hot reeking skin. Ophthalmia is common in the Desert, as well as in other parts of the East, and may be attributed as much to dirt and neglect as to any other cause.

The Bedouins are acquainted with but few medicines. The Desert yields some valuable simples, which are, however, rarely used. Dr. Sandwith, hearing from Suttum that the Arabs had no opiates, asked what they did with one who could not sleep. "Do!" answered the sheikh, "why, we make use of him, and set him to watch the camels." If a Bedouin be ill, or have received a wound, he sometimes comes to the nearest town, to consult the barbers, who are frequently not unskilful surgeons. Hadjir, one of the great chiefs of the Shammar, having been struck by

a musket-ball, which lodged beneath the shoulder-blades, visited the Pasha of Mosul to obtain the aid of the European surgeons attached to the Turkish troops. They declared an operation to be impossible, and refused to undertake it. The Sheikh applied to a barber who, in his shop in the open bazaar, quietly cut down to the ball, and taking it out, brought it to the Pasha in a plate, to claim a reward for his skill. It is true that the European surgeons in the service of the Porte are not very eminent in their profession. The Bedouins set broken limbs by means of rude splints.

The women suffer little in labour, which often takes place during a march, or when they are far from their encampment, watering the flocks or collecting fuel. They allow the children to remain at the breast until they are nearly two or even three years old, and, consequently, have rarely many offspring. (From *Discoveries in the Ruins of Nineveh and Babylon, being the result of a Second Expedition.* By A. H. Layard, M.P. London: 1853.)

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST. The fifth anniversary of this institution was lately celebrated at the London Tavern, Lord John Campbell in the chair, supported by three hundred patrons. The report which was read stated that since the opening of the hospital in 1848, upwards of 14,756 out-patients had been benefited by it. The expenditure for last year was £1755. The new hospital, Victoria Park, upon which £8000 has been expended, and the completion of which would require £8000, would be open early in summer for in-patients. At the close of the evening, Mr. R. P. Slater announced that the day's subscriptions amounted to £6000.

Medical Society of London.—The

Subjects for the FOTHERGILLIAN GOLD MEDALS offered for Competition by this Society are, for MARCH 1854, "Diseases of the Fetus in Utero, not including Malformations"; and for MARCH 1855, "The Pathology and Treatment of Diabetes".

Candidates for these Medals are informed that practical and original facts and illustrations will be considered as especial merits in all Essays sent in for competition, which must be written in the English or Latin language, copied in a fair and legible hand, and delivered at the Society's Rooms, 32A, George Street, Hanover Square, on or before the 1st of November preceding the award, with a sealed packet, containing the Author's name, and having on the outside a motto or device, corresponding with a motto or device on the Essay; that any Essay in the Author's handwriting, or with his name affixed, or which may in any way discover him, will be excluded from competition, and that the Prize Essay will become the property of the Society.

The Society also offers for competition two Silver Medals annually,—one to be given to a Fellow, and the other to an Honorary or Corresponding fellow, or to any Author, not a Fellow, who may contribute a Paper during the Session considered worthy of that distinction.

The learned of all countries are invited to become Candidates for these honours.

C. COGSWELL, M.D. } Hon. Secs.
E. SMITH, M.D. }

* * * The Fothergillian Medal for 1855 was awarded to ALFRED POLAND, Esq., for an Essay on "Wounds and Injuries of the Abdomen and their Treatment".

TO MEDICAL PRACTITIONERS.

A Gentleman, not qualified, who has

attended Lectures, &c., and is conversant with General Practice, including Midwifery, wants a SITUATION, in-door or out, in the Country or the Suburbs of London, where he would have to Dispense and Visit, or Dispense only.—Address, stating Salary and other particulars, R. B., 17, Cherry-street, Birmingham.

Just Published, post 8vo. cloth lettered, price 4s. 6d.; by Post 5s.

Lectures on the Nature and Treatment

of FEVER. By D. J. CORRIGAN, M.D., T.C.D., M.R.A. Physician in Ordinary to the Queen, in Ireland; Physician to Hardwick Fever Hospital, and to the Richmond Surgical, and Whitworth Medical Hospitals; Lecturer on the Theory and Practice of Medicine at the Carmichael School of Medicine.

Dublin: FANNIN & Co.; London: LONGMAN & Co.

Now ready, PART I, 8vo. sewed, price 12s., to be completed in Two parts.

A Text Book of Physiology. By

DR. G. VALENTIN, Professor of Physiology in the University of Berne. Translated and Edited from the Third German Edition, by WILLIAM BRINTON, M.D., Medical Tutor in King's College. Illustrated by upwards of 500 figures, on wood, copper, and stone.

London: HENRY RENSHAW, 356, Strand.

ASSOCIATION MEDICAL JOURNAL.

No. XII.

LONDON: FRIDAY EVENING, MARCH 25, 1853.

NEW SERIES.

THE RELATIONS OF THE COLLEGE OF SURGEONS OF ENGLAND TO THE MEDICAL PROFESSION.

MR. BRANSBY COOPER, in his oration delivered in the theatre of the College of Surgeons, on the 14th ultimo, in honour of the memory of JOHN HUNTER, had the good taste to avoid all reference to past or present causes of dispute between the Council of the College and the general body of the profession. In this respect he acted more wisely than some of his predecessors; and he has thereby deservedly gained the praises of the medical press. It is neither, however, for the purpose of again complimenting Mr. Bransby Cooper, nor of reproaching any of his distinguished predecessors, that we have now taken up the pen. Our object is more practical: it consists in a desire to give expression to a few thoughts which have been suggested to our minds by having been often asked, by junior members of the profession, why there is a total want of harmony between the Council of the College of Surgeons of England and those whom they nominally represent? and why the speaker of the Council, in the annual Hunterian oration, cannot, except at the risk of a tumult, advert to medico-political subjects?

The delicacy and the difficulty of these questions may cause us to answer them cautiously, and also to write with less passion than they inspire in many of our readers; but at the same time we feel that nothing can justify our avoiding their discussion in this Journal, as they lie at the very threshold of every inquiry which can be made into the nature of the reforms demanded by the present state of society and of the profession. It is not to exasperate difficulties, but to suggest grounds of conciliation and the basis of a lasting peace, that we venture to glance at this perplexed subject. We wish to make others feel, that which we sincerely believe, that with both parties there is a real community of interests; and that there is also, with both parties, an honest desire to do what will most advance the interests and insure the progress of the profession, even though that desire may occasionally be thwarted by the insidious bias of self-interest, or of that struggle for class-supremacy which springs from the sectional division of our profession.

The first topic which solicits our attention, is the position of the College as guardians of the Museum of Hunter.

It appears that there are two influences to be considered, which act at present in opposition: First, the moral responsibility (if we may use the term) of raising the standard of medical education, so that, among other results, the labours of Hunter may be duly appreciated by the mass of the medical profession; second, the necessity of obtaining money for the support of the Museum, and the payment of examiners and other officers.

Great and honourable as is the labour of preserving and adding to the Hunterian collection, and of employing it in the elucidation of the medical sciences, we maintain that the duty of its guardians has a much wider range; that, in

short, the elevation of the medical profession is closely connected with carrying out the work which Hunter began. We must not look on Hunter merely as a naturalist—though he was among the greatest of such; nor as a surgeon—though as such his name is honoured; but we must regard him as a man whose labours were calculated to advance his profession—and to elevate the standard of professional knowledge far above that of the age in which he lived and laboured. This result he produced; and the good effects of his labours are far from being exhausted after the lapse of nearly sixty years. It would seem, to adopt the expressions used by Mr. Bransby Cooper in his Hunterian Oration, “as if the advancement of surgical science, since his period, had tended to raise his fame; leading, in truth, to the belief that his example and his works had so extended the knowledge of his followers as to render them competent to estimate his due value, which, during his life, was not appreciated because his doctrines were insufficiently understood”.

The question then arises:—How far do the Council of the College of Surgeons fulfil the trust placed in them as guardians of the Museum of Hunter? how far do they endeavour to render the great body of the profession competent to estimate his true value?

The care and labour bestowed on the Museum, as a means of elucidating natural history and pathology, require no elaborate praise from us; nor need we enlarge on the additional value which it derives from the talent of an Owen and a Quekett; nor is it necessary to speak in commendation of the lectures delivered annually on comparative anatomy, histology, and pathology, for the illustration of which the preparations in the Museum are employed. We would, too, join with Mr. Cooper in congratulating the members of the College on the means which are being taken, by enlarging the building, “for increasing the capabilities of the collection, so that its resources may be progressively developed to a degree, the influence of which will, it is trusted, be beneficially felt by every branch of the medical profession”.

But it is also the duty of the College authorities to render the medical profession capable of appreciating the value of Hunter's labours—in other words, to raise it to a higher intellectual status. In this respect an amount of responsibility rests on them, over and above that which they share in common with other examining bodies.

But, alas, the possession of the Hunterian Museum actually furnishes a principle which acts in opposition to that to which we have referred.

No anatomical museum can be efficiently maintained without a great outlay of money; and the labour which the College bestows on the Hunterian collection obviously necessitates the provision of ample funds. For money, however, it almost entirely depends on the fees for its diplomas of Fellow and Member; and hence arises a temptation to encourage an influx of members, and to keep down the standard of education, in order that students may not be deterred from

becoming candidates for the diploma, and that the probability of rejection on account of insufficient knowledge may be diminished. We admit that the College does sometimes appear to exercise a wholesome severity against incompetent candidates; but we believe that the incompetency of the rejected is in a great measure due to the general facility of admission. Young men become lazy when they remember that a slightly crammed pastry-cook of Taunton, having got false certificates, had no difficulty in satisfying the Examiners of the College of Surgeons.

This then, is the position of the College of Surgeons:—they have to keep and improve the Hunterian collection, and their funds must be chiefly derived from the admission of Fellows and Members. If, then, they fail in their duty of elevating the standard of medical education, they are perhaps rather to be pitied than condemned, as their conduct is obviously not their choice, but the offspring of an imperious pecuniary necessity. Their imperfect curriculum, their superficial examinations, the repulsive coldness with which they treat comprehensive schemes of medical reform, (such as the Bill of our ASSOCIATION), and the sale of midwifery diplomas, are all very plainly the shifts and devices of men who dread impecuniosity.

A few months ago, it seemed as if the Council of the College had felt the force of the maxim

“Sera nunquam est ad bonos mores via”;

and had straightway resolved that midwifery, hitherto spurned by them, should be raised to its proper position in their examinations. They have, however, instead of incorporating an examination in obstetric medicine and surgery with that for their diploma, given to the license in midwifery an independent existence; and have even, by aid of their regulations, made it obtainable by persons who possess no diploma or license to practise medicine or surgery. It is the latter point on which we would especially comment; and in doing so we would refer our readers to the memorial of the Wakefield surgeons, published at p. 225 of our number for 11th March. The following is the College regulation to which we allude:—

“All other persons” (i.e., those who are not Fellows or Members of the London College, or who do not possess a diploma from some other College of Surgeons or University) “will be required to produce the following certificates:—Of being twenty-one years of age; of having been engaged for three years in the acquirement of professional knowledge; of having studied practical pharmacy for six months; of having attended lectures on anatomy and physiology, with demonstrations and dissections, during two winter sessions; of having attended one course of lectures on the practice of surgery; of having attended the medical practice of a hospital during twelve months; of having attended the surgical practice of a recognised hospital during twelve months; of having attended one course of lectures on midwifery and the diseases of women and children; and of having personally conducted twenty labours.”

That is to say, all persons who produce the certificates of attendance on lectures and hospital practice just enumerated—no matter how little they have profited by them in the acquisition of general professional knowledge—will be capable, after an examination in midwifery, of receiving a license to practise in that department. The result which must arise from the admission of such persons into the ranks of the profession, is well portrayed by Dr. F. H. RAMSBOTHAM in the *Medical Times* for January 15th. The development of the man-midwife into a “family doctor” is most truthfully delineated in the following sentences.

“It is universally conceded that the chief stepping-stone to general practice, among the less affluent at any rate, is attendance on cases of labour; nor can we wonder at that. If a woman has recovered satisfactorily after her confinement, and her infant is taken ill, to whom is it so natural that she should apply as to the person who assisted at the birth? When another child requires medical attendance, the same advice is sought. Both she and her husband send for him when they require ‘a little physic’, and thus that individual is established as the regular ‘doctor’ of the family.”

To those who already possess a diploma from some University or College, the midwifery license is for the most part superfluous, as this subject is recognised by most examining bodies. Those who have already obtained the diploma of the College of Surgeons, may, without detriment to the profession, be allowed to take out the new midwifery license; but with regard to the future, it is essential for the respectability of medical men that the midwifery test be incorporated with the general examination of the College, as is the case in Edinburgh. Let the Council obtain the abrogation of the absurd and mischievous bye-law, which prohibits members of their body from practising midwifery; and then, perhaps, we shall hear of their shewing more humanity to British ladies, and more regard to the honour and interests of their profession.

In conclusion, we would express a hope that it may, before many years, be our good fortune to hear or read an Hunterian Oration, in which medical politics may be gracefully introduced; and in which the orator may recapitulate, and the audience may gratefully acknowledge, the services rendered by the College towards the medical profession. But when will the Council of the College shew a mind as great in justice and liberality towards their brethren as was that of John Hunter in the comprehension of the works of nature? Not, we fear, till the legislature, responsive to the voice of an united profession, emancipates the College executive from the trammels of pelf, by making it no longer necessary, for the support of the Hunterian Museum and the remuneration of the members of the examining board, to sell a vast number of surgical diplomas or midwifery licenses. By such an endowment all would be gainers; sound science and brotherly feeling would flourish and increase; and the Reform Bill of our ASSOCIATION would lose half its terrors in the eyes of the Surgical Potentates of Lincoln's Inn Fields.

LORD LYTTTELTON'S VACCINATION BILL.

A VACCINATION EXTENSION BILL has been read a second time in the House of Lords. Its object is to eradicate small-pox by compulsory vaccination. We intended to have examined, in detail, the provisions of this Bill; but it is really so clumsy an attempt at legislation, that we do not think that it merits so much attention. So crude a measure never can, we think, become law; but as Lord Lyttelton, who introduced the Bill, has, apparently, no inclination to withdraw it, it becomes a question how, and how far, the profession ought to interfere in the matter? Some legislative measure is necessary; for, notwithstanding the existing acts, vaccination is extensively neglected, and the variolous epidemic has been very fatal of late, chiefly among the un-vaccinated. Moreover, it is very doubtful whether anything short of compulsion, or something approaching to it, will ever effect the general vaccination

of the poor. Still, the hostility which a compulsory act would naturally excite, and the odium which it would cast on one of the greatest of social blessings, ought to be well considered before the details of a measure based upon so doubtful a principle are finally determined. Meanwhile, it would be well to compare the results of the investigation made a few years since by our ASSOCIATION, with the forthcoming report of the Epidemiological Society; and thus to bring every possible ray of light into the arena of public discussion, before the nature of so important a measure is decided. The authors of the present Bill are not acquainted with some of the most important bearings of the subject.

As to its political aspect, we are not sure that it should be left to the management of such changeable and unstable bodies as boards of guardians. By protecting the poor, we protect the nation; and by vaccinating a poor man's child we destroy an arrow of death, which might otherwise have poisoned a parish or a city: it is, therefore, a national affair, and does not only concern pauperism. The existing acts ought probably to be wholly abrogated, and some provision substituted which shall more effectually provide for the actual vaccination of Her Majesty's subjects, not only here and there, where union surgeons and boards of guardians happen to be zealous in the cause, but also where zeal is most wanted, and neglect most palpable. One essential to good vaccination and vigilant zeal in its promotion, is the due remuneration of qualified vaccinators. This, the bill in question does not provide for; and thus it bears most unjustly on the medical profession, and makes a proportionably fallacious provision for the due execution of its objects.

The ASSOCIATION and the profession generally would do well to petition Parliament to reject this Bill; and then, if our Association were to appoint a Committee to meet the Small-pox Committee of the Epidemiological Society, for the purpose of agreeing in the provisions of a bill to be prepared without needless delay, we are not without hope that a really efficient and unobjectionable measure might be passed during next session. Nothing can be more injurious to the interests of the profession, and of society at large, than over hasty and random legislation on this important but somewhat difficult subject. We, therefore, invite the attention of our colleagues to the Bill, which we have reprinted at p. 264, so that each may form his own opinion, and then act as the emergency requires. Our own opinion is, that at present we ought to use our influence privately, and through petitions, to get the Bill thrown out of the House of Commons, as it will probably come down to that House from the Lords.

THE MEDICAL REFORM BILL.

It is with feelings of no ordinary satisfaction that we call attention to the hopeful aspect of the MEDICAL BILL of the ASSOCIATION, as disclosed by the report of the deputation to Lord Palmerston, and the letter from Mr. Hastings, printed at page 263. There is now a unity of action and a spirit of concession among all classes of medical reformers, which cannot fail to command success. When the Bill in its modified form is ready, we will publish it in the JOURNAL, along with a few commentaries.

ORIGINAL COMMUNICATIONS.

LETTSONIAN LECTURES FOR 1853.

By EDWARD WILLIAM MURPHY, M.D., Professor of Midwifery in University College, and Obstetric Physician to University College Hospital.

LECTURE FIRST.

FIRST STAGE OF LABOUR: IMPORTANCE TO THE PRACTICE OF MIDWIFERY OF A COMPETENT MEDICAL EDUCATION.*

MR. PRESIDENT AND GENTLEMEN,

THE very honourable office to which you have appointed me, imposes upon me duties which are both pleasing and responsible. My first and most pleasing duty is to tender to you and to the Council of this Society my warmest acknowledgments for the honour you have conferred upon me. My next duty is a most responsible one—so responsible, that I naturally feel some anxiety, some distrust, lest I should not accomplish my task in the manner I should desire.

You have heard from my predecessors most valuable lectures on highly interesting subjects connected with medicine and surgery. It is my duty to engage your attention equally in favour of midwifery; and with such an object, I confess that I have felt some difficulty in deciding upon the most attractive point of view in which I should present it to you.

This does not arise from any poverty in the subject itself; on the contrary, obstetric medicine is rich in interest, whether it be considered in a physiological, a pathological, or in a practical aspect. My embarrassment is much more the *embarras de richesses*. I might take the subject of parturition as a physiological question, and prove to you how deeply interesting to the physiologist is the observation of the phenomena of labour, but then I should involve you in a most difficult inquiry, and perhaps entangle you in a controversial web, from which I might not so easily extricate you.

I am at liberty to examine with you the pathology of the uterus, both in its unimpregnated and in its gravid state. If this were the question, a wide field of inquiry is open to us, that would afford an abundance of interest; but then, if I were to ask you to traverse it with me, so many questions in dispute oppose themselves, and I should have so many controversial gates to open in order to advance, that I fear such a trespass on your patience. The interest of the subject would hardly compensate for, or disguise the unpleasantness of having to wade through the mire of obstetric disputes.

I prefer, therefore, to present midwifery to your notice in a practical point of view; to consider the subject of parturition, its phenomena, its difficulties, its dangers, and then to inquire with you, whether it is not a duty of the first importance to rescue it from the consequences of that neglect which it has too long received, and to use our best exertions to place midwifery, both with regard to education and qualification, in the same position as medicine and surgery. On such a subject, I have no controversy to unravel; my difficulty is of a different kind. I have rather to ask you to aid me to overcome the *vis inertiae*—the dull weight of indifference that oppresses and retards the advance of this branch of medical science.

Before, however, we draw conclusions, we must first lay down our premises; and I shall in this lecture, having briefly explained the phenomena of parturition, point out to you where errors have been and may be committed in the management of labour, and where it is that ignorance too often causes unnecessary difficulty, and shelters itself from exposure, under the convenient cloak that nature affords her. It is an axiom, that "parturition is a natural process"; and therefore, whatever may occur in labour,

* This Lecture was delivered before the Medical Society of London, on March 9th, 1853.

Nature get the credit of it all. If the life of the unfortunate patient be not actually sacrificed; if it be only a greater delay and increased suffering; if an injury that may not show its effects for some months afterwards; if a difficulty, no matter how produced, that justifies a call for assistance; in all such instances, ignorance quietly makes her escape, and perhaps leaves to the consultant an undisputed claim to the merit of the case. "It was a very serious case—she did her best—she sent for the best assistance she could find—and from that moment was not further responsible." Such is the plausible justification that may conceal a host of blunders which converted a simple case into a most serious one.

My object is to point out where and how these blunders are committed, and to prove that the education of the obstetrician, whether in a scientific or in a practical sense, demands fully as much attention as that of the physician or the surgeon. Nay, I would say more: midwifery needs a more jealous guardianship, and for this reason; it does not possess any inherent power of protecting itself. The ignorant physician cannot succeed in his profession; because, if he know not how to combat the malady which he undertakes to cure, the progress of the disease will soon expose him. He can afford no relief, and the patient flies to a more skilful practitioner; or, possibly, an increasing mortality may soon terminate his career. If, therefore, medicine had no protection, if there were no examination required, the public now, just as they did centuries ago, would discriminate the wheat from the chaff. They would soon learn to appreciate the well informed physician, and would crowd round the Hippocrates, the Galens, the Celsuses of modern times, just as they did in the classic ages of Greece and Rome.

The surgeon who is unskilful, has a still less chance of escape; every case he meets with is an *experimentum crucis* of his knowledge. If it be the union of a fractured bone, the reduction of a dislocation, the removal of a limb, or even the passing of a catheter, his anatomical knowledge and his surgical skill are at once put to the test; his ignorance is immediately exposed, and the public are not long deceived.

I think I am correct when I state, that the most powerful plea in favour of a College of Surgeons, that which first proved its necessity, was afforded by the *palpable* mischiefs committed by ignorant men who had the hardihood to venture upon surgical practice. Their ignorance was felt as a grievance, and the remedy was applied.

Midwifery has not this advantage, because it consists neither in the curing of a disease, nor the repairing of an injury; but is essentially the scientific observation of a natural process. Nature herself combines the duties of the physician and the surgeon, and will generally succeed, even if unaided, in accomplishing the safe delivery of the parturient female. Sometimes, however, she cannot do so: difficulties interpose themselves; and then the necessity for the skilful accoucheur is acknowledged. The delivery cannot be completed without him, and a tardy admission is extracted, that education and skill are occasionally required even in midwifery. But such cases requiring interference bear no proportion to those that present themselves to the physician or the surgeon; and, consequently, the stimulus of necessity does not act in the same manner. Difficult cases are the exception, not the rule; and inasmuch as, in numerous cases, ignorant people seem to succeed very well in delivering women, the importance of a sound education is not so obvious as in medicine or surgery. But I would ask, Who can tell, in any given case, what the character of that case may be? Can any one say that flooding may not arise? that convulsions might not seize the patient? that an operation may not be required to deliver the child? And if it should happen that one single life is sacrificed through ignorance—not to say many lives; if some women are disabled through life, simply because their attendant knew nothing of parturition,—is it any answer or excuse for such a catastrophe, to say "that several women, attended just in the same way, never met with such accidents"? As well

might it be said that pilots are unnecessary, because ships are steered, often even through difficulties, without them. As well might it be argued, that the York Column, or the Monument at London Bridge, required no grating, because madmen do not always fling themselves from their summits. It required six deaths from the Monument to overcome the *vis inertiae* of the city of London: it would seem to require six hundred—I do not know how many more—to remove the incubus that oppresses obstetric medicine. If, however, the sophism to which I have alluded be admitted to be invalid; if it be granted, that it is the bounden duty of the public, or of those to whom the public have confided the responsibility, to use the most efficient means to secure the parturient female, in her hour of trial, against accident; if we allow that all women, under such circumstances, are exposed to risk, and require protection, although only a few may meet with such mischances,—it remains for me to prove that such protection can only be efficiently afforded by demanding of those who practise midwifery, an education fully equal and similar to that of the physician and the surgeon. It is my task to show you that the necessity for a scientific medical education is demanded in midwifery, the more urgently, because the very fact that women may be delivered with but little assistance, gives an encouragement to the ignorant, who are never remarkable for diffidence, to venture upon this branch of practice, where they dare not attempt it in either of the sister professions.

I shall first consider the manner in which the child is expelled from the womb, and point out the provisions of nature to secure the safe accomplishment of this process.

Let us suppose, then, the period of parturition to have arrived, and examine the conditions upon which its fulfilment depends. The child has attained its full intra-uterine growth; the womb, which envelopes it, occupies the whole of the abdomen; its mouth is closed, and the organ, thus immensely increased in volume, rests upon and above the pelvic cavity. In a mechanical point of view, then, we have to consider the body to be moved, the resistance to be overcome, and the power which impels it. The power exists in the muscular walls of the uterus, aided, when necessary, by the whole of the respiratory muscles. The resistance is three-fold: first, that which exists in the neck of the womb itself; secondly, that arising from the pelvis; and thirdly, that produced by the tissues which close the outlet of the pelvis—a resistance which constitutes the chief support to the pelvic organs in their ordinary state.

The body to be moved may be considered almost as an inert mass, yet not completely so. It seems to me to exert a certain independent, although limited, power to aid its expulsion. The motions of its limbs excite more efficiently the contractions of the uterus in the first stage of labour; and the motions of its head, in the second stage, seem to me not entirely dependent on the pelvis. The effect of pressure, perhaps the pain produced, leads it intuitively to alter the direction, so as to diminish these effects, and consequently to seek the widest space. This will be best observed by contrasting cases where the child is living, with those where it is dead before delivery. Labours are seldom so active (to use obstetric language) in the latter as in the former case.

The muscular power of the uterus is of enormous magnitude. This is well known to the practical accoucheur, who is occasionally obliged to pass his hand into the uterine cavity, to overcome these contractions, and to deliver the child or the placenta. The resistance he meets with would be insuperable, if he trusted alone to the antagonism of forces in order to oppose it successfully. If the whole of this power were exercised for the purpose of forcing open the mouth of the womb, the most serious consequences would ensue; the structure of the cervix could not resist this force; it must be torn by it, and a laceration be the result, which might extend through the peritonæum, and destroy the patient. Let us consider the manner by which nature controls and regulates this power. The most accurate observers have arranged the fibres of the uterus into certain sets of muscles, which we shall briefly con-

merate. On the external surface of the uterus, the fibres arrange themselves so as to form fan-shaped muscles, diverging from the round ligaments, which thus fulfil the duty of tendons. These muscles give great support to the womb during its growth, and now are the first to contract. They draw the womb down upon the pelvic cavity, keep it fixed in its position, and prevent a divergence to either side, which, by increasing the obliquity of the uterus, would derange its action. Thus, before the pains of labour are noticed, these muscles contract, gradually draw down the uterus, and render the abdomen less prominent than before; so also the walls of the uterus, felt through the abdomen, are more firm and resisting—a certain indication that other contractions will soon take place, that constitute the pains of labour. These occur in the fibres on the inner surface of the uterus, which arrange themselves into two sets, surrounding the openings of the Fallopian tubes, and forming concentric muscles. Some fibres pass round the lower portion of the uterus in irregular circles; these are especially to be observed at the junction of the body and neck of the uterus: others, but very difficult to trace, pass downwards towards the mouth of the womb, surrounded and imbedded in a large quantity of condensed cellular structure. By this arrangement, the simultaneous contraction of all the fibres of the uterus would equally reduce its volume; the walls of the womb would contract, and converge towards a common centre in its cavity: but a contained body, being compressed equally on all sides, would remain stationary. It is necessary that there be a succession, an order, in these contractions. The expulsive muscles must expand the opposing tissues: the fibres contained in these structures support them, and prevent over-distension; the former precede the latter in their contractions, and act alternately with them. The fundal muscles, those surrounding the Fallopian tubes, form the great expulsive force of the uterus; the fibres of the lower portion of the body and cervix are the guardians of its structure: the one set is in some degree, in opposition to the other, but that is more apparent than real. It is most essential that anything like antagonism between muscular forces be avoided; and, therefore, it is necessary that there should be some means of communication that will harmonise their actions. It is in this sense that the womb affords so beautiful an illustration of the reflex function of the nervous system: a perfect correspondence is maintained between the cervix and the fundus of the uterus, by which all collision is avoided. If the fundal muscles contract, the fibres of the cervix are passive; if the cervical fibres are excited to contraction, the fundal muscles suspend their action. So also the effort of the fundus uteri to distend and open the cervix must not be viewed merely as an illustration of mechanical power; there is, through the same reflex medium, a vital action set up, which, more than any other, contributes to the safe accomplishment of this object. The structure to be distended and opened is prepared for that purpose; the highly condensed cellular tissue of the cervix becomes softer, more yielding, more abundantly moistened with mucus; and sometimes what might be called an act of dilatation, takes place—the whole of the structure yields to the force of the fundus, with a suddenness that resembles, and has been mistaken for, the relaxation of a sphincter muscle. There is abundant evidence to prove, if time allowed me, that the fibres of the cervix do not perform the office of a sphincter muscle; and I am happy on this point to have the support of your late distinguished Lettsomian Professor, Mr. Hancock, who has shown you that neither in the bladder (an analogous viscus) do the circular fibres of its neck fulfil such a duty. "And so likewise in the bladder, the longitudinal fibres are more developed and stronger towards the fundus, whilst towards the middle and neck we find the circular and transverse in greater abundance. But I am not inclined to consider either these, or the analogous fibres round the lower part of the rectum, in the light of sphincter muscles."*

Notwithstanding all these means to facilitate the opening of the womb, there still remains a difficulty to remove. The highly condensed tissue of the cervix varies greatly in its density, and is at this time more than usually vascular: it is, therefore, easily inflamed; any irritation applied would first excite, and then derange, the order of uterine action. The irritation is instantly communicated to the fundus; its contraction follows. The structure of the cervix may not yield; and if so, the irritation is increased. Ultimately, inflammation of the cervix sets in; the muscular fibres existing there contract spasmodically; and the fundal muscles cease to act, or only act irregularly. All this would happen in the majority of cases, if the child were driven down as a wedge to force open the womb. Some provision is, therefore, necessary to avoid this; and thus you will perceive the importance of the final duty of the amnion and its contained fluid. The liquor amnii, surrounding and protecting the fœtus on every side, until it is able to protect itself, accumulates upon the cervix uteri, and conveys through a fluid medium the power of the fundus. By this means, the force is not merely directed upon the os tincæ, but is diffused and equalised. You are aware that any force applied to a contained fluid is distributed equally to every point of whatever contains it. On this principle, the force of the fundal muscles is not alone communicated to the cervix uteri, but is distributed to every other part of the uterine cavity; consequently, it is reflected against the fundus itself, so that, if the action of these muscles should be too powerful, they are opposed and controlled by their own reflected force.

Besides this, the fluid thus interposed between the child and the neck of the womb removes all irritation. If the os uteri dilate, the fluid insinuates itself within it; if any irregular contraction or unusual resistance occur at the cervix, the liquor amnii at once yields, but at the same time maintains a steady pressure. If the fluid enters within the circle of the mouth of the womb, the force of the fundus is conveyed by it directly against the margin of the os that surrounds it. Thus it is that a force possessing immense power is kept under perfect control, and at the same time rendered most efficient for the object which it has to accomplish. With such safeguards, it might be supposed that a steady, continuous action of the fundal muscles would soon open the womb, and expel its contents, just as occurs in the bladder or rectum; but this is not the case. Every one knows that the action of the uterus is an interrupted action, returning at intervals of variable length, the periods of repose being longer than in any other of the hollow viscera. Why is this? It is a further evidence of caution. The tissues of the cervix expand slowly, and not only is a sufficient, sometimes a very long time required for this purpose, but the structure itself must be relieved from the irritation which a continued pressure against it would certainly produce; hence the necessity for intervals of rest. The experienced obstetrician is well aware how these intervals are sometimes lengthened, where there is more than usual resistance to be overcome; he knows that the action of the uterus may be even suspended when previous efforts fail, or are producing irritation: but in ordinary cases this interrupted action of the uterus is equally a proof of the caution with which every possible provision is made to guard against injury to the opposing structure. Nature adopts for her principle, *Arte non vi*—"Time, not force"; and those who would follow her, must be content to walk in her footsteps.

In the whole of this process by which the womb is opened, there is nothing that calls for assistance. Neither medical nor surgical aid is demanded. If no accidental causes interfere with her, Nature is all-sufficient; and any one—the midwife, the nurse, the friend—may act as her handmaid; because, in fact, they have nothing to do but to offer consolations, a virtue which the midwife possesses in a most remarkable degree. But, unhappily, accidental causes do interfere, and so derange these operations, that it requires all the judgment of the educated physician, and sometimes the skill of the experienced surgeon, to bring

* *Lancet*, 1852, vol. i, p. 213.

the patient safely through the difficulty. Sometimes the accidents are unavoidable, and will happen irrespective of the most judicious treatment; but too often they are the results of ignorance, and would have been avoided, but for the mischievous dogma that places the parturient woman in the hands of ignorant persons. It is said, "labour is a natural process, and therefore any one may practise midwifery". Let us examine the consequences of this doctrine.

One of the causes that interfere with the efforts to dilate the womb, exists in the structure of the cervix; it may be more than usually dense and unyielding, and, notwithstanding all the provisions that nature has made to allow it to expand gradually, and to avoid irritation, still she sometimes fails: the tissues of the cervix will not relax—they become irritated—inflammation sets in, and what is called, in obstetric language, "a rigid os uteri" is the result. The consequence is, that this stage of labour is not only protracted, but the pains experienced by the patient become agonizing. The consolations of the midwife afford no comfort, and therefore she proceeds, to use her own language, "to assist the labour"; that is, she endeavours, by her manipulations, to dilate the vagina, and to open the mouth of the womb. The result is, that the inflamed cervix is yet more inflamed, the inflammation extending both to the vagina and body of the uterus. No doubt the membranes are also ruptured, perhaps intentionally; the head of the child is forced down upon these tender tissues; its body is tightly grasped by the uterus, in obedience to that law which prevails in all involuntary muscles, to seek a state of contraction; and although these contractions are increased during the pains, yet in the intervals the fibres are never perfectly relaxed. What, then, is the result? The agonies of the patient are increased in a ten-fold degree; she is dissipated by the great protraction of the labour, and exhausted by her sufferings; her friends are equally so. The midwife thinks it would be well to have another opinion; assistance is sent for; and then it is found to be absolutely essential to remove the child. There is only one operation available under such circumstances—one by which the child, if alive, is destroyed:—the head must be perforated, and the brain removed, in order that, thus reduced in size, it may be brought through the passages. In most instances, however, of this kind, the child has already ceased to exist; it dies in the womb, in consequence of the great pressure maintained on the circulation in the funis and the placenta. But this is not the only bad consequence; the patient herself, although delivered so far safely, is still exposed to risk from the pre-existing inflammation. It may reach the peritoneum, or engage the veins of the uterus, and end in the most fatal results.

In such a case as this, then, two lives may be sacrificed from mere ignorance. The inflammation was not recognized when it might have been arrested. When the difficulty that it caused is at length found out, the inflammation is considerably increased by the means that are used to overcome the obstacle; until ultimately ignorance acknowledges that the case is past her skill, and the consultant has to share all the onus, if not the odium, of these melancholy consequences.

I am persuaded that the Fellows of this Society, who practice midwifery, will bring to their recollection examples of mismanagement such as I have quoted, and will admit that I have not overdrawn the picture which I would present to you. With regard to my own experience, I may state that during my residence in the Dublin Lying-in Hospital, several such cases were sent in from the country, in which we had no alternative but to deliver them; and thus the number of perforations performed in that establishment were greatly increased beyond what they otherwise would be. To avoid an operation, is a much greater proof of skill than to perform one, and in no instance does that remark apply with more force than in the operation under consideration,—one in which the life of the child is necessarily sacrificed, and that of the mother placed in such danger, that, according to the most accurate statistics, one life in five is generally lost.

These cases are, unfortunately, not the only ones that

illustrate my argument. I shall direct your attention to one of a different kind that may arise during this stage of labour—one that requires for its management the soundest medical experience.

The womb, in its non-gravid state, is frequently the seat of a low inflammation, that shows itself prominently during the catamenial period, but subsides in the intervals. The leading symptoms are, extreme pain during menstruation, and a scanty discharge. We call it dysmenorrhœa, and relieve it by hip-baths, aperients, and sometimes depletion and anodynes. The popular theory of our treatment is derivation: we either endeavour to draw blood from the uterus, or relieve the circulation by taking blood elsewhere; but we are, in fact, treating the inflammation, which prevents the uterus from fulfilling its proper function. Now this inflammation is accompanied by a very remarkable condition of the nervous system. The neck and body of the uterus can generally be touched and examined, without causing much pain; the os tincæ is almost insensible. In these cases, however, pain is exalted to its highest intensity; if an examination be made by touch, the patient can hardly bear the finger to pass along the vagina; if the mouth or neck of the womb be examined, the pain is very great; and if the body of the womb be compressed, the patient suffers agony. This local distress is accompanied by that general nervous irritation which is so familiar to you as hysteria, and upon which I need not dwell.

Fortunately, these women do not generally conceive; but this sometimes happens. When they become pregnant, the new demand upon the constitution often relieves the prominent symptoms; they are less hysterical, and have no longer the agonies of dysmenorrhœa: but still they are much more irritable than other patients in similar circumstances; they are much more liable to uterine pains; and hence, during pregnancy they have frequent attacks of pain in the womb,—a uterine neuralgia, that is sometimes called rheumatism of the uterus. The motions of the child also often distress them very much. But these are only trifling inconveniences, when compared with those which take place when the period of parturition arrives. When these patients have to endure the pains of labour, then, indeed, their sufferings reach a climax. The pain that accompanies the action of the uterus in an ordinary, or what might be called a healthy labour, is no measure of the agony caused by its contractions when in this morbid state: consequently, the amount of suffering to which such patients are exposed, is more than they can bear. It is sufficient to overcome the fortitude of any woman; and women are remarkable for their fortitude in this their hour of trial. In the present case, however, the patient does not possess that fortitude; she is very impatient of pain; is highly irritable; and watches, with intense anxiety, every returning contraction of the uterus. The consequence is, that these contractions are feeble and inefficient. The influence of the mind on the uterus is familiar to every experienced practitioner. A slight shock, a surprise, will arrest the action of the uterus; but in these instances the sympathy (from this morbid derangement) is still more marked; hence the very apprehension of pain arrests the contraction, and, after hours of suffering, very little progress is made, although the cervix uteri does not present any unusual resistance.

Let us, then, suppose such a case in the hands of an ignorant person; the pains are too violent to be relieved by consolations, and therefore something must be done. "The pains are doing no good": warm stimulants are given; these failing, ergot of rye is perhaps tried as a display of medical knowledge; the uterus contracts spasmodically, the agonies of the patient are greatly increased; but this temporary effect soon ceases, and leaves the patient more exhausted, and more dispirited than ever. Possibly, the same manipulations may be attempted as in the former case, and the attendant endeavours to dilate the mouth of the womb mechanically. Fortunately, the patient can hardly bear this; but, if she should, the result is the same—~~inflammation~~ inflammation of the os and cervix sets in, and the difficulty is greatly increased. At length we arrive at the same point.

clusion as in the former instance. Ignorance can do no more; the case is past her skill, and assistance must be obtained: perhaps she may not make so honest a confession, but rather allow the anxious friends to arrive at the same conclusion. They urge her to have a second opinion, she is too conscientious to offer the slightest opposition—and aid is sent for: but under what circumstances? The patient is worn out by protracted suffering; the constitution may have received a shock from the intensity of pain, which gives rise to the most serious consequences; atony of the uterus, with its attendant, hæmorrhage, may occur at any time during the labour; convulsions may take place; and if the practitioner is fortunate in escaping these evils, and safely delivering his patient, still he is exposed to the risk of a protracted recovery; because a patient so exhausted is much more liable to attacks of fever or of inflammation than are healthy women.

Such a case as this requires the aid of the educated and experienced physician, as completely as any case of hysteria that he undertakes to treat. The disordered actions dependent on the womb in its unimpregnated state are the object of the physician's attention, and are acknowledged to require for their treatment all the advantages of a sound medical education: but the very same derangements, when the womb is gravid and is about to expel its contents, become, from this accident, unworthy of his care. The simple fact of the womb being gravid, and not gravid, seems to form the line of demarcation between ignorance and education. I am sure, sir, you will admit that such a position is untenable, and that cases like these, as well as those previously alluded to, prove that the obstetrician requires an education fully equal to the physician or the surgeon.

Thus far I have confined your attention to labours that are called "natural", where no assistance is required, and where it is assumed that there is no occasion for a medical or a surgical education to understand its management. Those labours, however, which are exceptions to the rule are acknowledged to require something of this kind, but then it is argued that whenever assistance is needed in such cases, it can always be obtained as soon as the necessity is known. This is not always true, especially in country districts. It is my duty, however, to point out to you that the argument itself is invalid. If, for instance, I were to direct your attention to those labours that are called "preternatural", those in which some other part of the child than the head presents, I could point out many instances, where the life of the child has been lost because the attendant did not know what assistance to give, or how to give it. Most of these, however, belong to the second stage of labour; and as I wish in the present lecture to confine your attention to the first stage, I shall only mention one instance in which ignorance sometimes contrives to do irreparable mischief.

When the arm and shoulder of the child are found to present at the mouth of the womb in place of the head, the case is one where art must supersede nature: the acknowledged rule of practice is to deliver the child, the moment that it can be done with safety to the mother. It is, therefore, of the greatest importance that this deviation be recognized early in the labour, and that the person in charge be prepared to turn and deliver the child, the moment a favourable opportunity presents itself—that is, as soon as the mouth of the womb is sufficiently open or sufficiently yielding to admit the hand to be passed through it without risk. Now, if a case of this kind unfortunately fall to the lot of an ignorant person, the worst consequences ensue. Nothing, whatever, is known of the presentation in this stage of the labour—their skill does not consist in recognizing positions; everything is done to console the patient under her sufferings; vain promises are made that "the birth will soon come"; perhaps stimulants are given to support her strength; but at last the period arrives when all these means fail, and an examination is made to ascertain the cause of the delay. It is then found out for the first time that the labour is unusual; the arm is felt in the vagina, and assistance is promptly sent for; but under what circumstances? The membranes are broken, and the liquor amnii has been dis-

charged long before; the uterus is contracted strongly about the body of the child; the protruding arm may be swollen so as to fill the whole vagina. To turn the child, under such circumstances, is always an extremely difficult and sometimes a most dangerous operation; the child never escapes, and I have known cases where the uterus was ruptured in the attempt. Thus, in fact, one life is certainly lost, and possibly both: because the patient has had the misfortune to entrust herself, in the first instance, to an incompetent person. Time, which was of the highest value, was lost; the period at which the child could have been delivered safely, and without risk was unnoticed, and the difficulty was only ascertained when it became dangerous.

I shall take another example of a still more serious character from the class of complex labours. It sometimes happens that the after-birth is attached to the mouth of the womb: and when it is thus situated, hæmorrhage is the necessary consequence of the dilatation of the os uteri. The most frightful flooding may take place the moment the womb opens, or the discharge may return with every pain in a less degree and gradually exhaust the patient. I know no case in the whole range of obstetric practice that requires more decision or more promptitude, nor one in which the line between ignorance and education is more strongly marked; because, here, ignorance has not time to take refuge behind a second opinion. Flooding will not wait; and if the proper treatment be not carried into effect in the first instance, the patient's life is sacrificed to the delay. In order, however, that this treatment be adopted, the nature of the case must first be ascertained, the attendant must know that the placenta presents, and here it is that ignorance shines so conspicuously. She knows nothing whatever about it; the hæmorrhage alarms her, and it is well if she does not leave the unfortunate patient to her fate. One fact is worth a thousand arguments, and I shall in illustration quote one case from Dr. Waller's valuable clinical remarks.* "The patient", he reports, "had been under the care of a midwife, who, on the preceding day, finding hæmorrhage, ruptured the membranes; this not succeeding, she left her. Another woman was sent for in the evening, who also got alarmed at the bleeding, and like her predecessor decamped, leaving the sufferer to her fate. A medical man saw her on the following morning, who immediately requested my (Dr. Waller's) attendance. At that time the hæmorrhage had abated, the pulse, though rapid and soft, was not so feeble and faltering as I have frequently witnessed in similar cases: there was a general warmth of the surface; but the countenance was deathly and corpse-like. On introducing the hand for the purpose of examination, the placenta was easily felt lying in the vagina, but no portion of the child; the knees presented. The child was readily drawn down: some difficulty was experienced in bringing the head through the pelvis. Notwithstanding the discharge was trifling, the signs of sinking had increased. . . . After an interval of about fifteen minutes, the pulse fell, the patient threw back her head on the pillow, and instantly expired."

Thus, from mere ignorance, was this woman's life sacrificed. All the aid that Dr. Waller could afford, failed, because it was too late; and even the effort of nature, the complete separation of the placenta, was unavailing, because, although the hæmorrhage had abated, no timely aid was given to save the patient from its effects.

Time will not permit me to trespass further on your attention this evening; but I trust that I have succeeded in proving to you the dangerous consequences that result, even at this stage of labour, from ignorant persons undertaking the practice of midwifery; and that the death of the parturient woman, and much more frequently the death of the child, is too often attributable to this cause alone. I might also advance instances in which, although the patient escaped with her life, the foundation had nevertheless been laid of very serious diseases, which left her a patient ever afterwards. I need only allude to that much controverted subject, inflammation and ulceration of the neck of the womb.

* Medical Times, January 16th, 1848.

"This disease is produced by various causes; but the history of such cases points to none more common than a previous labour, in which inflammation of the os uteri had commenced, had been unnoticed, and had been suffered to advance until the tissues became disorganized. When labour was concluded, and the patient recovered from its immediate effects, the inflammation which had but imperfectly subsided, was readily reproduced.

If such facts are true, you will admit that it proves the importance of a competent education among those who practise midwifery; and not only so, but the necessity of excluding from this branch of practice, those who do not prove themselves competent. I shall reserve to the concluding lecture some further observations upon this part of the subject.

In my next lecture, I shall enter upon the consideration of the second stage of labour.

Henrietta Street, Cavendish Square, March 1853.

GALACTAGOGUE AND EMMENAGOGUE EFFECTS OF WARM AND STIMULATING APPLICATIONS TO THE MAMMÆ.

By JOHN ROSE CORMACK, M.D.

DR. J. O. M'WILLIAM published in the *Lancet* of September 7th, 1850, some very interesting details regarding the use, among the natives of the Cape de Verd Islands, of fomentations with the leaves of the *Ricinus Communis* and *Jatropha Curcas*, for the purpose of accelerating and bringing on, or increasing the flow of milk when the secretion was tardy or deficient after childbirth; and in the *London Journal of Medicine* for October 1850, Dr. Tyler Smith described some trials made by him with the leaves of the *ricinus communis*, for the purpose of showing that similar galactagogue effects might be produced in London as in Boa Vista, by adopting measures similar to those employed by the natives of that island. The method adopted by Dr. Tyler Smith was essentially that detailed by Dr. M'William.

Dr. M'William's account of the native practice is as follows:—

"The *bofareira* (*ricinus communis*) grows in most, if not all, the Cape de Verd Islands. That used by the natives for the purpose I have mentioned is called by them *white bofareira*, to distinguish it from what appears to be nothing more than a variety of the same species, the *red bofareira*. The white, or that which possesses galactagogue qualities, is recognized by the natives by the light green colour of the stem of the leaf; whilst the leaf-stem of the *red* is of a purplish red hue. The latter plant is carefully avoided, as it is said to be a powerful irritant; and if applied, as it occasionally has been, by mistake for the *white*, it produces an immediate and often immoderate flow of the menses.

"In cases of childbirth, when the appearance of the milk is delayed, (a circumstance of not unfrequent occurrence in those islands), a decoction is made by boiling well a handful of the *white bofareira* in six or eight pints of spring water. The breasts are bathed with the decoction for fifteen or twenty minutes. Part of the boiled leaves are then thinly spread over the breasts, and allowed to remain until all moisture has been removed from them by evaporation, and probably in some measure by absorption. This operation of fomenting with the decoction, and applying the leaves, is repeated at short intervals, until the milk flows upon suction by the child, which it usually does in the course of a few hours.

"On occasions where milk is required to be produced in the breasts of women who have not given birth to, or suckled a child for years, the mode of treatment adopted is as follows:—Two or three handfuls of the leaves of the *ricinus* are taken, and treated as before. The decoction is poured while yet boiling into a large vessel, over which the woman sits, so as to receive the vapour over her thighs and generative organs, cloths being carefully tucked around her so

as to prevent the escape of the steam. In this position she remains for ten or twelve minutes, or until the decoction cooling a little she is enabled to bathe the parts with it, which she does for fifteen or twenty minutes more. The breasts are then similarly bathed, and gently rubbed with the hands; and the leaves are afterwards applied to them in the manner already described. These several operations are repeated three times during the first day. On the second day, the woman has her breasts bathed, the leaves applied, and the rubbing repeated three or four times. On the third day, the sitting over the steam, the rubbing, the application of the leaves, and the fomentation of the breasts, are again had recourse to. A child is now put to the nipple, and in the majority of instances it finds an abundant supply of milk. In the event of milk not being secreted on the third day, the same treatment is continued for another day, and if then there still be want of success, the case is abandoned, as the person is supposed not to be susceptible to the influence of the *bofareira*."

Dr. Tyler Smith did not subject his patients to the steaming process.

From a number of observations which I have made at various times, and in cases of very different character, I am fully satisfied that the cases of Drs. M'William and Tyler Smith do not in any way support the notion of a special galactagogue power belonging to the leaves of any particular plants. It will be found, I think, that simple warmth, still more hot fomentations, and in a yet higher degree stimulating embrocations and cataplasms, have an extraordinary power in exciting the mammary glands to the secretion of milk, even in circumstances apparently the most adverse to the performance of their function. The leaves of the *ricinus communis* and of the *jatropha curcas*, when applied to the mammæ, produce decided stimulation; as we might expect, when we remember that they belong to the natural family *Euphorbiaceæ*, of which acridity is the leading character. This acridity exists in a very high degree even in the seeds of the *ricinus communis*; and Pereira quotes, along with similar cases, the case of a girl, eighteen years of age, who died of gastro-enteritis, from eating about twenty of these seeds.

My object at present is to establish, by the brief narration of a few facts, the following propositions:—

- 1st. Warmth and stimulants applied to the mammæ often act powerfully as *galactagogues*.
- 2nd. Warmth and stimulants applied to the mammæ often act powerfully as *emmenagogues*.
- 3rd. The leaves of the *bofareira* (or *ricinus communis*) and *jatropha curcas* act as *galactagogues* and *emmenagogues*; but not from their possessing any peculiar or specific power.

I. WARMTH AND STIMULANTS APPLIED TO THE MAMMÆ OFTEN ACT POWERFULLY AS GALACTAGOGUES.

CASE I. MILK RESTORED TO THE MAMMÆ BY HOT FOMENTATIONS. Last month, a lady, when nursing her infant, about seven months old, was attacked with acute bronchitis of moderate severity, which was successfully treated by low diet, and tartar emetic in small doses. At the end of four days, the bronchitis was cured; but the milk, which had previously been failing, almost entirely left the breasts. On the fifth day, from exposure to cold, she experienced a relapse of the bronchial affection. As she had been considerably weakened by the previous attack, and as the symptoms of the relapse were not sufficiently severe to justify recourse a second time to antimony, I ordered her to take a draught containing ammonia and chloroform, as an *anodyne*, expectorant, and diaphoretic, every eight hours; and to carry out similar intentions, I also directed a succession of pillow-cases, filled with heated moist bran, to be applied to the chest. When I saw her on the following day, after the treatment had been employed, she told me that she had profusely perspired for some hours; she was (after copious expectoration) free from cough, and pain in the chest, and, what was equally a source of pleasure and surprise,

her, *her breasts had become distended with milk.* This lady was able to resume nursing, and to continue it with the assistance of a suitable diet.

CASE II. EFFECTS OF A SINAPISM APPLIED TO ONE OF THE MAMMÆ OF A LADY, FIVE MONTHS ADVANCED IN PREGNANCY: EFFECTS OF WARMTH IN THE SAME CASE. A lady was under my care for bronchitis, at the same time as the patient whose case I have just sketched. She was directed one night to apply a sinapism over the sternum, which she did, but having fallen asleep, it slipped to the side, and remained undisturbed for about an hour upon one of the breasts. For some days, this mamma was very much larger in size than the other, and its areola was also much darker. From the delicacy of this lady, and the unusual severity of the weather, I directed her to wear a double flannel jacket, and a wadded wrapper round the chest. She tells me that *the breasts are larger, and the areolæ much deeper in colour than they ever were in any of her ten previous pregnancies even at the full time;* and these conditions were established while her general health was exceedingly depressed by illness.

CASE III. STIMULATING EMBROCATION INCREASING THE SUPPLY OF MILK. A lady, though in excellent health, had a very scanty supply of milk for her infant, when it was a few weeks old. She consulted me as to the use of means to remedy this evil; and I advised her to rub the mammae gently, every six or eight hours, with an embrocation containing a small quantity of tincture of cantharides and oil of thyme, and to sheath the mammae very warmly in wadding. *In a few days the milk was abundant.*

CASE IV. HOT POULTICES KEEPING UP THE SECRETION OF MILK WHEN THIS WAS NOT DESIRED. A lady suffered, after her confinement, from a succession of abscesses and abortive abscesses in the breast. The surgeon who attended her treated her by antiphlogistic medicines, under which discipline she passed some wretched months, from mental and bodily depression, aggravated by hysterical attacks. The local affection did not seem to make any satisfactory progress; and the great obstacle to a cure was stated to be the impossibility of getting rid of the milk, in spite of saline purges being freely administered. The mammae during the whole of the period to which I refer, had been ceaselessly treated, night and day, with hot poultices and medicated fomentations. These applications were abandoned, and a generous diet prescribed. *In a few days there was not a drop of milk in the breasts;* and the abscesses, actual and threatening, had ceased to give any pain, and had, in fact, almost disappeared.

I might refer to other cases, which I have vividly in my memory; but the above, which have occurred within the last three months, seem sufficient to establish the first proposition; viz., that *warmth and stimulants applied to the mammae often act powerfully as galactagogues.* I need hardly add, that along with the use of such means, the regular application of an infant to the breast would greatly assist in reproducing lactation, as, according to the testimony of various authors, this stimulus has of itself proved sufficient to restore the secretion of milk, and has actually caused it to flow, not only from virgins and other women who had never been pregnant, but even from males.* Excitement and sanguineous turgescence of the gland is induced; and these conditions afford to the organ both a power and a stimulus to perform its previously dormant function.

II. WARMTH AND STIMULANTS APPLIED TO THE MAMMÆ, OFTEN ACT POWERFULLY AS EMMENAGOGUES.

Warm clothing of the abdomen and limbs, hot hip-baths, and medicines which stimulate the bladder and rectum (such as ergot, cantharides, and aloes), have undoubtedly emmenagogue powers in properly selected cases of retarded or suppressed catamenia; and, indeed, they constitute, in various combinations, the principal measures by which the physician usually endeavours to excite the ovarian nius

upon which menstruation depends. The observant physician knows well, that while his treatment is directed to the uterus through the ovaries, the effects produced upon the mammae are generally very striking, and the first indications which he expects to find of the uterus being roused from its torpor are turgescence and tingling of the mammae; phenomena which also usually precede normal menstruation. It is equally true, though not so familiarly understood, that measures which act directly and primarily upon the breasts, such as warm clothing to the bust, and the application of stimulants, not only cause them to swell and throb, but likewise stimulate the ovaries, and cause the menses to flow. The practice adopted by some practitioners, of applying leeches to the mammae in amenorrhœa, owes its efficacy to fomentations used, and the irritation of the bites.

In 1834, Dr. Charles Patterson published, in the *Dublin Journal of Medicine*, a paper in which he described the emmenagogue power of irritation of the mammae by sinapisms. This paper fell into my hands at the time of its appearance, when I was an Edinburgh dispensary pupil, practising, I believe, with more zeal than knowledge, and using, often with more confidence than discrimination, that plan of treatment which I had seen most recently or most enthusiastically recommended. In these circumstances, I successfully employed Dr. C. Patterson's method in amenorrhœa. The beneficial results which I then obtained, produced a very strong impression upon my mind as to the efficacy of irritation of the mammae in producing menstruation; and the experience of nineteen maturer years has confirmed this impression.

As Dr. Patterson's facts do not seem to be referred to by subsequent writers, and as the practice which he recommends is so little noticed by authors, I subjoin an extract from his paper. Dr. Patterson writes as follows:—

"Mary Reardon, aged 24, of moderately corpulent habits, was admitted into the Rathkeale Hospital on the 10th of August 1832. She laboured under slight synochial fever, which in a few days yielded to venesection and purgatives. On the 19th August, symptoms which were considered of a hysterical character presented themselves, with pain in the upper and outer part of the right side of the chest. For the latter affection, a small sinapism was prescribed; but from inattention of the nurse, it was made so large, that it covered a considerable portion of the mamma. The sinapism remained on for half an hour. At the visit on the following morning, the 20th August, Reardon complained that the right breast was exceedingly painful—the pain being very different in its character from that which she had before experienced. On examination, the whole side of the chest was found considerably swollen: there was slight diffused redness of the skin; and though the mamma itself was enlarged to four or five times its natural bulk, yet there was no circumscribed hardness, nor any tendency to suppurative inflammation. On the 21st August, the right mamma and adjoining parts of the chest were found much more enlarged than they had been at the preceding visit. The left mamma and side of the thorax were unaffected; and it was announced by the nurse that the catamenia had that morning appeared, and were then in considerable quantity. This discharge, which, as the patient stated, had been for two years and a half wholly suppressed, continued to flow for two days; then it began to decline, and with it the tumefaction of the mamma gradually disappeared." (pp. 193-194.)

Dr. Patterson's attention having thus accidentally been directed to mammary irritation as an excitant of the torpid uterus, he resolved to try its efficacy when a suitable opportunity presented itself. His next case is thus described:—

"Catherine Power, aged 19, applied to me on the 14th September 1832. She complained of headache, languor, loss of appetite, and inability to attend to her usual business, that of a servant. She stated, that about the middle of April, the menstrual discharge being then present, she incautiously exposed herself to cold in washing clothes at

* Cases in which men have suckled children are on record. The essential character of the gland is the same in both sexes.

a river. The catamenia then suddenly ceased, and had not since returned; and from that period she had been constantly subject to ill health. She had consulted different medical gentlemen, and taken a great variety of medicine, with little advantage. I directed that the clavicular half of the right mamma should be covered with a sinapism. It was allowed to remain on for thirty minutes; and on visiting her in six or seven hours after its removal, I found the whole right breast considerably swollen, hot, and painful. The next morning, the enlargement of the mamma was very much increased, the tumefaction having extended to the clavicle and axilla of the irritated side. There was no hard circumscribed or prominent tumour, but a painful, diffuse, elastic distension of the mammary gland, and surrounding cellular substance. On the evening of the day next succeeding the application of the sinapism, this poor girl with much joy reported that the catamenia had appeared. The flux having continued for two or three days in moderate quantity, she then found herself greatly relieved of the headache and other most distressing symptoms; and in a week her health was so far restored, that she ceased to require any further attendance." (pp. 194-195.)

I am disposed to regard irritation of the mammae as a convenient and rapid agency for the induction of menstruation; but one which must neither be rashly nor indiscriminately employed. In numerous cases it may be used alone; but, generally speaking, it may be advantageously combined with other means.

In cases of acute suppression of the menses, I am in the habit of prescribing, along with sinapisms to the mammae, warm clothing of the bust and limbs, and the hot hip-bath every twelve hours.

In anæmic amenorrhœa, it need hardly be stated, that irritation of the mammae is only calculated to do good in conjunction with, or after a course of, a metallic medicine, such as some of the preparations of iron, manganese, or arsenic. In such cases, where we can trace a monthly ovarian nîsus, though there be no catamenial flow, these periods should be seized as the appropriate times for using the sinapisms, and then also we may sometimes, by venturing a few doses of forcing medicine, such as cantharides and ergot, bring the case at once to a favourable issue.

The emmenagogue effects ascribed to the application of the leaves of the ricinus communis, by Drs. M'William and Tyler Smith, can easily be understood, when we remember their irritative character, and the consequences which we have found to be induced by irritation of the mammae caused by other stimulants.

"When the breasts", says Dr. M'William, "are small and shrivelled, the plant is said to act more upon the uterine system, bringing on the menses if their period be distant, or causing their immoderate flow if their advent be near."

In the subjoined case, related by Dr. Tyler Smith, the effect produced may have been owing partly to the application to the breasts, and partly to the application to the genitals.

"I have used," says Dr. Tyler Smith, "the remedy in a case of scanty menstruation of a remarkable kind. Owing to exposure to marsh malaria some years ago, the patient had scarcely a sign of coloured discharge at the usual catamenial periods. She used the infusion of the leaves of the red bofareira at the date of her period, applying the infusion and leaves to the breasts, and the vapour to the genitals, with the effect of producing, in two days, a considerable flow of the catamenia."

III. THE LEAVES OF THE BOFAIREIRA DO NOT PRODUCE THEIR GALACTAGOGUE AND EMMENAGOGUE EFFECTS IN VIRTUE OF ANY SPECIFIC PROPERTY.

The facts which have been already cited, point out pretty plainly that the effect of the leaves of the bofareira does not depend upon any specific property possessed by them; but simply on the determination produced by warmth and the irritative juices which they contain. That a good

deal depends upon the mere warmth of the poultices, is sufficiently obvious. I have seen frequent examples in my own practice. I will not, however, enter into the particulars of these cases; but will conclude by mentioning two circumstances, which thoroughly corroborate this view.

In the *Boletín de Medicina, Cirujía, y Farmacia* of 14th November, 1852, a short abstract was given of Dr. M'William's paper. In the same journal of the 19th December following, a correspondent writes to say, that in consequence of the notice which had appeared of Dr. M'William's paper, he had used fomentations of fig-leaves (*hojas de higuera*) to promote the secretion of milk in three cases, in which it had wholly or nearly ceased. In all the cases the benefit was decided. The Spanish practitioner wrote to confirm the practice recommended by Dr. M'William, but he has in reality, by using the wrong leaves, shown very clearly the galactagogue effects of poultices and fomentations, even when destitute of stimulating properties. I may likewise here state, upon the authority of a Spanish lady (with whom I conversed on this subject a few days ago), that in Cadiz women are in the habit of bringing back the milk to their breasts after it has left them in consequence of weaning the child, or of any other cause, by means of drinking an infusion of the wild lupin (*altramuz*), and applying to the mammae fomentations made with the same plant. This plant has no stimulant or irritative quality, and the efficacy of the poultices made with it must, as in the case of the fig-leaves, depend simply on heat and moisture, as in a common poultice. The internal use of the infusion might be dispensed with.

IV. CONCLUSION.

I have now made out a good plea in favour of warmth and irritation of the mammae, being regarded as powerful galactagogue and emmenagogue agencies; and I have also shown that the interesting facts recorded by Drs. M'William and Tyler Smith are not examples of specific action, but illustrations of a general principle, which may be rendered available in rational therapeutics.

Injurious effects may so readily be produced by *excessive irritation of the mammae* upon themselves, upon the ovaries and uterus, and (as a consequence of the undue excitement of any of these organs) upon the whole system, that, in following the practice recommended in this paper, it is necessary to proceed with caution.

FIRST, as regards the *mammæ* themselves, care must be taken not to produce too much irritation, lest troublesome inflammation be excited in them, and in the glands of the axilla;—consequences which I have seen produced in such a degree as to require, for several days, cooling lotions and general antiphlogistic measures.

In irritable subjects, or when the effects of the treatment cannot be daily ascertained, stimulating embrocations ought to be preferred to sinapisms. When sinapisms are applied every eight or twelve hours, for some days continuously—as is sometimes necessary—they ought to be compounded of two or three parts of bread to one of mustard; and a fold of soft linen ought to intervene between them and the skin. By attending to these conditions, patients will generally endure the poultice without injury for half an hour or an hour; and a greater amount of benefit will be obtained than by causing violent stimulation for a short period. It is always essential to maintain, during the intervals, great local warmth, by means of abundance of cotton wadding. If mammary irritation have been carried so far, through mistake or accident, as to necessitate recourse to refrigerating lotions and lowering treatment, it need hardly be remarked, that the object for which it was used is not likely to be accomplished.

SECONDLY, as regards the *ovaries* and *uterus*, the effects produced upon these organs must be attentively watched; for the very greatness of the power which irritation of the mammae exerts over these organs, may constitute an element of danger. In endeavouring to excite mammae,

we must take care that we do not excite inflammation of the ovaries, or of the womb. When we find the patient complaining of severe pain in the loins, and suffering from general fever, we ought at once to discontinue mammary irritation, and prescribe rest in bed, abdominal fomentations, and the frequent use of the hip-bath. In cases of this description, as in ordinary attacks of dysmennorrhœa, we may often not only relieve pain, but accelerate a resolution of the inflammation, by administering opiate enemata.

Caution on the part of the practitioner will generally enable him to prevent or speedily remove the evils and inconveniences to which reference has been made. They may, however, so easily occur through the want of it, and lead to so much discredit and embarrassment, that I have been anxious to give them the prominence which they deserve.

Essex House, Putney, 19th March, 1853.

ON DISTICHIASIS.

By HAYNES WALTON, Esq., F.R.C.S., Surgeon to the Central London Ophthalmic Hospital, Assistant-Surgeon to St. Mary's Hospital, etc.

DISTICHIASIS having been lately brought before the members of the Association through the medium of our JOURNAL, I am desirous to record my own views respecting that condition of the eyelashes which this term is meant to imply.

Distichiasis, from *dis*, twice, and *σῆλος*, a row (one of the many pedantic words that yet obscure the writings devoted to diseases of the eye), is usually employed to signify that a second, or supplemental, row of cilia or eyelashes exists; but the correctness of this, as a pathological state, I dispute. The matter is not devoid of practical interest, and this I purpose to show in a subsequent communication on the treatment of certain affections of the eyelids.

I maintain that the supposed new row consists of the natural cilia merely displaced; and that the idea of super-added eyelashes is an error, which arises out of the normal yet irregular disposition of the manner in which they are set on the lid, and which becomes very apparent when the extremities of those which are most internal are turned inwards and away from those which are most external. The deception is still greater, when abortive cilia supplant those along the inner margin of the eyelid, and grow without any curve, but straight, and incline rather towards the eyeball than in any other direction. I have observed examples of abortive eyelashes growing inwards, nearly at a right angle to the tarsal cartilage. Of the truth of the assertion of the irregular disposition alluded to, any one may convince himself by selecting for experiment a healthy eyelid, separating the most internal of the eyelashes with a probe, and producing the so-called distichiasis. This is, in fact, what is done by disease, and is effected in three ways—by the agglutination of some of the cilia with lachrymal secretions, in certain affections of the conjunctiva, or of the Meibomian glands, in consequence of which they are turned against the eyeball; by long-continued malposition in inversion of the eyelid; and, most frequently of all, by disease of the edge of the eyelid, producing pathological changes in the dense fibro-cellular tissue that surrounds the hair follicles, and perhaps also by changes in the follicles themselves. A case, remarkably illustrative of the last clause, came under my notice at the Central London Ophthalmic Hospital. A lad was brought there with chronic inflammation of the upper eyelid, of three years' duration, by which the edge of the lid was considerably thickened, and the eyelashes separated into two distinct rows. Several months afterwards, when all traces of preternatural vascularity had ceased, and the eyelid had nearly recovered its natural size, the duplex arrangement of the cilia was no longer apparent.

So far as I am aware, there are not any physiological facts that at all support the theory of hair being developed after foetal life; that is, there is not on the surface of the

body any secondary formation of hair follicles, these being of primary existence. The appearance of hair on parts apparently devoid of it, after the application of blisters, or the accession of increased vascular action, has been often advanced in proof of the secondary creation; but this argument is quite demolished by the fact that the entire surface of the body, with the exception of the palms of the hands and the soles of the feet, is thickly set with hair follicles; and by the deduction from this fact, that when hair is so accidentally developed, the phenomenon must be ascribed to hyper-nutrition of normal germs.

Those who contend for the existence of distichiasis, but cannot overcome the fact of there being no secondary creation of hair, declare that the irregular eyelashes, although proceeding from old hair follicles, perforate the lid more internally than natural. This cannot be, unless the hair pass through the tarsal cartilage (a supposition that is manifestly absurd); for the most internal of the eyelashes, as every one who has dissected the eyelids minutely, knows, issue as close as it is possible by the side of the cartilage.

In the *Dublin Quarterly Journal of Medical Science* for February 1853, the reviewer of my treatise on "Operative Ophthalmic Surgery", makes the following remarks on this question:—"It has always appeared to us surprising, that any one could imagine this extraordinary growth, how it could be, or why it should be produced. We have examined a very large number of persons affected with the disease under consideration, and could not, in any case, discover the extra number of cilia, comparing the diseased with a sound eye in the same person—the only possible way, we maintain, by which a fair and correct opinion can be formed; for it is obvious that, if we were to compare the number of cilia to be found in the lids of one suffering from the complaint, with those in sound eyelids in another person, we would be proceeding upon very irregular principles, were we to found any argument upon such data."

60, Brook Street, Hanover Square, March 1853.

REMARKS ON A NEW KIND OF CATHETER, MADE OF VULCANIZED INDIA-RUBBER.

By W. VINER BEADLE, M.D.

FINDING, in a case some time since under my care, that the ordinary catheters produced or kept up irritation of the mucous membrane of the bladder, and produced also great general disturbance, I was induced to try a catheter made of vulcanized India-rubber.

CASE. Mr. H., aged 80, had at different times suffered from incomplete retention of urine; but the attacks had always hitherto passed off without instrumental assistance. In this attack, after exposure to cold, he had felt colicky pains in the umbilical region, combined with slight diarrhœa. He had constant calls to micturition, though unable to pass more than a small quantity at a time, and that in drops. In a day or two, the retention becoming urgent, and the pain severe, although urine was still passed, he applied for assistance. The bladder, having become more distended, had in the same ratio lost more of its contractile power, and no longer possessed the power of lessening its cavity, or expelling the contents. Such was the state in which I first saw him, on the 16th of July. Being five or six miles from my residence, and unable to return that night with instruments, I prescribed fomentations and an anodyne. These measures afforded little relief.

July 17th. Early this morning, I used the catheter, drawing off a good deal of urine, of a dark colour, and which, on cooling, showed a considerable deposit of mucus. The catheter passed easily; and the prostate, though tender, did not seem greatly enlarged. I prescribed the following pills to be taken at bed-time, and an aperient draught in the morning:—

R. Pilulæ hydrargyri,
Pilulæ saponis comp. aa gr. v. Ft. pil. ij.

July 18th. The urine was drawn off. It was still dark,

and contained a good deal of mucus. He had had frequent calls to micturition in the night; the urine, however, coming only in drops. He had slept but little, and felt very uneasy. The pulse was 90; the tongue pale and furred. He was ordered to take at night five grains of the compound soap pill. A diaphoretic mixture, with hyoscyamus, was also ordered to be taken during the day.

July 19th. He had slept a little after the pill, but was very uneasy this morning. The urine was, if anything, more loaded with mucus, mingled with lithates. It had an acid reaction on litmus. The compound soap pill at bed-time was repeated; and he was ordered to take some castor oil in the morning.

July 22nd. He had taken the pill each night; but on this day, notwithstanding the sedatives, etc., the tenderness of the perineum had increased, and the pain in the bladder was greater, accompanied with smarting, and extending through the pelvis and hips. The effects of irritation on the general system were also more marked, and accompanied by flushes and slight rigors; and a tendency to low fever seemed rapidly setting in, whilst the bladder was assuming that state of chronic inflammation which so soon gives rise to the acute form, reversing, as it does, the ordinary course of inflammation. I prescribed as follows:—

R. Pulveris Doveri,
Sodæ sesquicarbon.,
Potassæ nitratis, aa gr. v. M.

Fiat pulvis 4tis horis sumendus.

July 24th. Since the 22nd, he had taken the last prescribed medicine regularly, with veal broth and barley water, freely as diluent. In some respects he had been relieved.

From the very frequent calls to micturition, it had been found necessary to keep the catheter constantly in the bladder, though removed each day. The long coils had, no doubt, by its being frequently passed, been one cause of keeping up the irritation of the mucous membrane of the bladder, and more especially of the prostate; both these organs being at all times, under such circumstances, exceedingly liable to become irritable. The urethra also was discharging mucus, and one of the testes had begun to swell.

Under these circumstances, I resolved to try the effect of a vulcanized India-rubber catheter; and I procured some small tubing of that substance for the purpose. I then placed *within* one extremity the end of a catheter, cut off for the purpose, and about an inch and a half long, snipping out a small piece of the tube corresponding with the eye of the inner piece. The extremity was then carefully closed, cemented, and smoothed. When well greased, it passed, without much difficulty, on a stiff stilette; and was not removed for a week. By the injection of warm water, the tube was easily kept free from mucus or other obstruction.

In a few days, under the use of anodynes, beef-tea, arrow-root, and wine, etc., he had so far recovered as to be able to walk in his garden, feeling but little inconvenience. The tincture of sesquichloride of iron was soon after exhibited; and he continued the compound soap pill for some time at night. Under the use of the iron and the catheter, the bladder soon recovered its powers. At the end of nearly two years, the patient is now hale, hearty, and well, for a man so greatly advanced in years.

REMARKS. In this case, the ordinary catheters seemed, by their firmness and the length of their coil, to produce irritation of the urethra and bladder, and, by their frequent passing, also of the prostate—all already so prone to it. From the comfort with which the vulcanized India-rubber tube was borne, the cessation of uneasiness and irritation, the facilities which it afforded the muscular fibres of the bladder to recover their tone, dilating or contracting as it does with each motion of the urethra, it was certainly of great benefit in this case. In one or two other cases in which I have adopted a similar instrument, it has fully answered my expectations. In cases similar to that which I have described, the vulcanized India-rubber catheter seems to offer great advantages.

Tewkesbury, Gloucestershire, March 10th, 1853.

CASE OF MALFORMATION AND COMPLICATED DISEASE OF THE URINARY ORGANS.

By SPENCER THOMSON, M.D.

THE accompanying drawing may interest the readers of the ASSOCIATION MEDICAL JOURNAL; in the first place, on account of the malformation which it represents, and in the second, as an illustration of the distinctly traceable effects of complicated disease.

- A. Right kidney: ureter double.
- B. Left kidney: vessels double.
- C. Union of canals of double ureter.
- D. Right renal vein.

- F. Right renal artery.
- G. Left renal vein, double.
- H. I. Left renal arteries, double.
- L. Opening of left ureter into thickened bladder.

The figure represents the kidneys, ureters, and bladder, taken from a young man who had suffered severely from stricture of the urethra. He subsequently became the subject of diabetes insipidus, and finally died in consequence of suppression of urine. The case occurred in the practice of Messrs. Tomlinson and Tome, of Burton-on-Trent, who kindly afforded me the opportunity of making the drawing from the parts.

On the right side, the enormously dilated ureter is double; on the left, there is a double set of renal vessels. The bladder, not larger than usual, is considerably thickened.

Unquestionably, the thickening of the bladder must have been directly occasioned by the stricture; and its dilatability being thus impaired, it must have become less than commonly adapted to accommodate the extra accumulation of urine, which the combination of diabetes and stricture necessarily involved. The confined fluid, consequently, must have been dammed up within the ureters; and to such an extent, apparently, had this

taken place, that these tubes were dilated to a calibre equalling that of the small intestines, which, indeed, they greatly resembled. Moreover, the valves of the kidneys were likewise much dilated, and the cortical substance diminished to a corresponding extent, for the glands themselves were not enlarged.

Haunton, Burton-on-Trent, March 1st, 1853.

CASE OF GLANDERS IN A FEMALE.

WITH REMARKS ON THE TRANSMISSION OF THE DISEASE FROM THE HORSE TO THE HUMAN SUBJECT.

By ARCHD. WM. COCKBURN, M.D.

CASE. Mrs. Slims, aged 52, wife of a cab-driver, was seen by me on Friday, 4th February, 1853. She had been in bed for nine days, complaining of feverishness and rheumatism. When I saw her, she had excessive pain in the extremities, especially the lower limbs. The ankles were red, swollen, and tender, but not glazed. On the right forearm there was an abscess the size of an egg. The body and limbs were covered with spots, some of a bright livid colour; others with pus; some like mere pimples; and on some parts there were patches similar to erythema. On the forehead, over the right temple, was an ulcer, or rather a cluster of vesicles injured by a blow since their formation. This ulcer was irregular and superficial, with dark, ragged, angry looking edges, and trifling discharge; it was about the size of a half-crown. There was much thirst and fever. The pulse was quick and small; the tongue dry and foul; the urine scanty and high-coloured; the countenance depressed and anxious. She had been slightly delirious the previous night, but was now sensible. She was ordered to take a mixture of acetate of potash, every two hours, and a pill of soap and opium at night. A poultice was applied to the forehead and arm, the feet and ankles were wrapped in cotton wool.

February 5th. She was much the same; had had some ease, and two hours' sleep after taking the pill. The feet were not quite so red, but still very painful. The urine was clearer, and more abundant. She had had one dark, offensive motion. She was sensible, and complained of pain in the stomach from the medicine. The acetate of potash mixture was changed for one with colchicum and hyoscyamus; and a pill with colchicum and conium was ordered to be given at night.

February 6th. During the night, a sudden discharge of very offensive dark-coloured pus took place from the nose, at half-past ten, A.M. She was drowsy all night, but was sensible when roused. She had not passed urine, unless in bed. The bowels had been moved once, and the motion was less offensive. The nostrils were dilated, and clogged with dark glairy matter; the throat was full of viscid phlegm, with difficulty of expelling it: the eyes were swollen and closed, with copious discharge. The pustules were abundant all over the body; none seemed to have burst, except on the forehead, where bruised. The pulse was weaker; the tongue moist, but coated; the arm better. The wool had not been removed from the ankles. The attendant said that the matter from the nostrils was peculiar and sickening. The patient was almost in a state of low delirium. The colchicum was omitted, and she was directed to take bark, with diluted hydrochloric acid and stimulants, also an expectorant.

Vespere. She was more sensible. The phlegm was very copious, but more easily expectorated. The nostrils were much dilated, and discharged a dark sanious fluid. The pustules generally appeared more suppurative; some over the chest were as large as a sixpence, full of pus, but without inflamed edges round them; those on the legs were in all stages; and the patches of erythema were very bright. The eyelids were closed, but she could open the right one. She had taken some porter. Bark and expectorant were continued, and the eyes were ordered to be well washed with warm water.

February 7th. She died at half-past two o'clock in the morning.

REMARKS. On my first visiting the patient, the state of fever, the severe pain of the joints, and the redness and swelling of the ankles, led me to think that she was suffering from acute rheumatism. I concluded that the pustules over the body were of the epidemic character that has so long prevailed, and that the occurrence of the acute rheumatism at the same time was merely accidental. The urine being scanty and high-coloured, I prescribed (what I have never found to fail in acute rheumatism) the acetate of potash every two hours, with a pill of soap and opium at bed-time. But this opinion did not satisfy me. There was an indefinable expression about the patient, and a varied peculiarity about the appearance of the eruption, for which I could not account; and I left her with the unsatisfactory conclusion that she was very seriously ill, and that I did not know what was the matter with her. As I passed through the stable (she lived in the loft) on my way out, I asked her husband if his horses, three in number, were healthy, and he said that they were so.

On the next day, her general appearance was in no way improved. She had a low typhoid look, and yet she was sensible and collected. The urine had improved: but as the general symptoms had not, I altered her medicine, and gave her colchicum with an anodyne.

On the third day, the sudden and profuse discharge of sanious matter from the nose; its peculiarly offensive, sickening odour; the dilated nostrils; the sudden affection of the throat; the swollen, discharging eyelids; with the more suppurative character of the pustules, at once induced me to set down the disease as glanders. Accordingly, I prescribed bark, with diluted hydrochloric acid, an expectorant, and stimulants. In the evening, my opinion was more confirmed.

The patient died about six hours after my evening visit.

I examined the three horses. They were all in sound health; their nostrils dry; their eyes free from discharge; they had no coughs; their coats were in good condition; but one had grease in the near hind leg. Though denied by the husband, there seems no doubt that the woman had washed this leg. The disease was not extensive, but still it was a leg discharging matter.

Her constitution seems to have been very susceptible of absorbing poison: for, two years ago, she injured her finger when attending as nurse on a patient with a suppurating wound of his leg, and she suffered much then from pustular fever and eruption.

In the present attack, she had been ill for eight days before I saw her. Farcy had preceded the glanders; though Professor Dick says "the two diseases are only modifications".*

Entertaining some doubts as to the possibility of the discharge from grease conveying glanders, I begged my friend Mr. Lizars to ask the opinion of Mr. Williamson, veterinary surgeon of Edinburgh, on this point. Mr. Lizars, in reply, writes to me thus:—

"I have read over your views on glanders to Mr. Williamson, who corroborates the greater part of them. He says that if you inoculate a horse with the matter from a leg affected with grease, or quittor, or foul sore, the horse will become affected with glanders. Therefore, there can be no doubt that the poor woman caught the disease from the horse's leg. Glanders often commence with farcy."

Two points in this case struck me as remarkable. First, as noticed by Dr. Graves,† "the variety of inflammatory actions observed in the skin"; second, as noticed by Dr. Ballard,‡ "the close resemblance in the condition of the nervous system to that in delirium tremens".

BIBLIOGRAPHICAL NOTICES.

URINARY DEPOSITS, THEIR DIAGNOSIS, PATHOLOGY, AND THERAPEUTICAL INDICATIONS. By GOLDING BIRD, M.D., F.R.S., etc. 12mo. pp. 473. Fourth Edition. London: 1853.

A FOURTH and enlarged edition of this classical treatise will be cordially welcomed by a numerous body of the best class of medical practitioners. The popularity and rapid sale of former editions not only speak loudly in favour of its merits, but likewise proclaim a highly advanced state of general professional knowledge; for without such knowledge, combined with a zealous and conscientious spirit of scientific inquiry, the labours of Dr. GOLDING BIRD could not have met with that hearty welcome which they have received, and which they so well deserve.

It would be out of place to give an analysis of a work which is so well known as that now before us; and we have only to state that the present edition contains considerable additions, especially in the chapters devoted to the therapeutic action of remedies. The chapter which treats of "Blood-depuration by the kidneys as a remedy in disease" is an important contribution to the philosophy of therapeutics; and we would particularly call attention to the author's remarks upon the *substitution of renal depurants for mercurials*. On this point he says:—

"I would most anxiously urge upon my professional brethren the importance of giving a fair and patient trial to the acetate of potass, in a large class of ailments where the blood is obviously in an unhealthy state, especially where glandular engorgements and furunculous eruptions exist. Indeed, in many of these forms of chronic indisposition in which there is no evidence of organic mischief, but where the general health is depressed, the face sallow, the urine coloured by purpurine, constituting the condition in which the patient is popularly said to be 'bilious', the advantage gained by the use of this remedy is remarkable. Hitherto, whenever a remedy influencing the general health through the capillary circulation is required in chronic disease, we generally fall back upon mercury; indeed, a mercurial and an alternative are nearly convertible terms. Instead then of trusting to mercurials nearly exclusively, or after they have been administered without benefit, or in the strumous diathesis, where for the most part they are not well tolerated, I would advocate the use of renal depurants, especially of acetate of potash.

"Although in these remarks I have especially alluded to the acetate of potash, yet I have merely selected it as a type of a large class of remedies, many of which equal it in their remedial effects. The citrates and tartrates of potass and soda constitute remedies of probably equal value. Indeed the utility of the popular 'saline draughts' of these salts is in all probability to be explained by their influence as renal depurants. The solutions of potass and soda, as well as their carbonates, are most useful remedies of their class, but decidedly of much less value than the acetates and citrates. Two reasons may be given for this; first, they are very likely to become neutralized whilst in the *primæ viæ*, by acids, which, like the hydrochloric and phosphoric, are not decomposed whilst passing through the circulation; secondly, the conversion of acetates and citrates into carbonates takes place in the blood, and thus they in the *nascent state*, when their chemical tendencies are the highest, come in contact with those matters which it is important to eliminate from the blood. It is well known that a considerable quantity of liquor potassæ is required to render the urine even neutral, whilst a few grains of an acetate or a tartrate will rapidly render it alkaline." pp. 441-443.

LITHOTRITY AND LITHOTOMY. By WILLIAM COULSON, Surgeon to St. Mary's Hospital. 8vo. pp. 388. London: 1853.

THE substance of this work was delivered in St. Mary's Hospital in the form of lectures, which were subsequently published in the *Lancet*. In its present improved form it must be regarded as the most complete monograph upon Lithotritry and Lithotomy which has yet appeared in our language. Even when the reader cannot exactly adopt the

conclusions of the author, he will find that the information imparted is so fairly and fully given, as to enable him to form his own opinions. The value of the work to the surgeon and the student is much enhanced by ninety-seven wood cuts, and a good index.

JAMES COPLAND, M.D., President, in the Chair.

PATHOLOGY OF OBSTRUCTION OF THE VEINS (OBSTRUCTIVE PHLEBITIS), AND THE NATURE AND PROXIMATE CAUSE OF PHLEGMASIA DOLENS. BY F. W. MACKENZIE, M.D.

THE author observed that, since the publication of the late Dr. Davis's paper on the proximate cause of phlegmasia dolens, in the twelfth volume of the *Medico-Chirurgical Transactions*, the profession had generally recognised the important relations which subsist between certain lesions of the crural veins and the general phenomena of the disease. The facts adduced by Dr. Davis had been fully substantiated; but the theory based upon them had not been so generally accepted; for, whilst many, with Dr. Davis, regarded the lesion of the veins as the proximate cause of the disease, others regarded it rather as a secondary effect, or as an incidental circumstance. The author's investigations were therefore directed, in the first place, to a solution of this question; and, having stated the distinctive characters of phlegmasia dolens, as given by Callisen and Hull, he proceeded to investigate how far these were producible by inflaming and obstructing, by various means, the iliac and crural veins of dogs.

EXPERIMENTAL INVESTIGATIONS. Three series had been made: first, the effects of ligaturing the iliac veins, as observed at definite periods after the operation; second, the effects of irritating the whole length of the lining membrane of the iliac veins, by means of chemical and mechanical irritants; and third, the effects of sustained compression and contusion of the femoral veins. In illustration of the first series, the effects of ligaturing the iliac veins were minutely detailed, as noted at periods of 24, 48, 72, and 96 hours, and 9 days, after the operation; and illustrative drawings of the dissections were given. The author pointed out the difference between inflammation of the iliac veins, thus induced, and the ordinary symptoms of phlegmasia dolens. In particular, the constitutional effects were very transient, being most marked on the day of operation, and subsequently rapidly subsiding. The local effects were also transient rather than persistent, and were confined to swelling, stiffness, and inability to move the extremity. There was no tenderness or preternatural heat of the limb; the swelling was of a simple oedematous character; and it and the other local symptoms rapidly passed away in a few days. He then described, in a general summary, the condition of the iliac veins at the several specified periods after ligature; the limited character of the inflammation; the absence of extensive coagula in the veins; and the general dissimilarity between the condition of the veins, and that met with in phlegmasia dolens. These phenomena were strictly in accordance with those which had been observed from time immemorial, in connexion with wounds, injuries, and operations upon these vessels.

The results of more extensive irritation of the iliac veins were then detailed. This part of the inquiry comprised, first, the effects of applying a strong solution of nitrate of silver to the lining membrane of the iliac veins, from the femoral up to the cava; and second, the effects of forcibly introducing a solid piece of bougie into them, throughout their entire length, and securing it there for several days. From the results of these experiments, illustrated by drawings, it was clearly shown that inflammation of the iliac veins, thus extensively induced, was not capable of giving rise to phlegmasia dolens. A similar conclusion was arrived at with regard to the results of long-continued compression and contusion of the femoral vein.

The author concluded, from these experiments, that phlegmasia dolens could not be dependent upon mere inflammation of the crural veins; and that, therefore, such inflammation could not be regarded as its proximate cause. Nevertheless, clinical history and *post mortem* examinations showed that lesions of the crural veins, although not the proximate cause,

must yet be regarded as an essential pathological constituent of the disease; and must be rationally accounted for, in common with its other pathological characters.

ORIGIN, NATURE, AND CAUSES, OF OBSTRUCTION OF THE VEINS. This subject was investigated more particularly in relation to local and constitutional causes. In pursuing this inquiry, the author treated in detail of the influence of irritation and inflammation of the external and internal coats of veins; of changes primarily and independently taking place in the blood; and of the conjoint influence of irritation of the lining membrane and the blood, in giving rise to the phenomena in question. In numerous cases, strong solutions of nitrate of silver, and other chemical irritants, were extensively applied to the external coat of the veins of dogs; and in others, it was severely contused, and otherwise mechanically injured. The general results appeared to justify the conclusion that, whilst the external coat of veins very readily reacted under the influence of irritating causes, and quickly developed the anatomical characters of inflammation, such inflammation was neither disposed to extend in the course of the vein, nor to give rise to obstructive phlebitis. In all the cases, the vein was not obstructed, nor was the lining membrane inflamed. The correctness of these conclusions was sustained by clinical facts.

In investigating the effects of irritation and inflammation of the lining membrane of veins, it would be necessary first to study these in veins from which blood had been altogether excluded; for thus only could we learn the exact share taken by the lining membrane of the vein in the causation of obstructions. Gendrin had observed, that such irritation of the lining membrane of veins rapidly gives rise to exudation of lymph, and thus to entire obstruction; and Dr. Mackenzie had applied solutions of various irritants, such as nitrate of silver, bichloride of mercury, and sulphate of zinc, to the lining membrane of veins, at the same time excluding the blood. The results, in a variety of cases, tended to disprove the opinion of Gendrin, and to show that very irritating solutions might be applied to the lining membrane of veins, without giving rise to perceptible exudation of coagulable lymph; and that, therefore, veins were not ordinarily obstructed by such exudation. In all the observations, the morbid appearances of the vein were strictly limited to the irritated portion; inflammation, therefore, of the lining membrane, as of the external coat, was not disposed to extend indefinitely. The application of this fact to the pathology of veins was briefly indicated.

The influence of primary and independent changes in the blood, in giving rise to obstruction, was considered under two heads: first, the influence of extreme vital prostration in giving rise to spontaneous coagulation of blood in the veins; and second, the action of various abnormal matters in the blood, in producing coagulation, irrespectively of any action of the veins. The first question arose from the fact, that it had been assumed that polypi in the heart and great vessels were a consequence of extreme prostration. The author had repeatedly bled dogs, and kept them on a limited supply of food; and had also had recourse to mechanical compression and ligature of some of the principal veins, but these had failed to give rise to obstruction beyond the ligatures. Two cases were reported in illustration, in one of which the femoral veins of a parturient bitch had been ligatured after considerable bleeding; and the author concluded that veins were seldom obstructed from purely vital prostration. He could not subscribe to the opinion that a coagulum in a vein acted as a foreign body, and so gave rise to phlebitis; because, in the cases in which the iliac veins had been ligatured, and a coagulum formed on the distal side of the ligature, this had been found in adherent, and the vein healthy, at periods of twenty-four and forty-eight hours after the coagulum had formed.

In considering how far veins might be obstructed by morbid matters in the blood, producing coagulation independently of the veins, the author examined the views of Mr. Henry Lee, and pointed out several sources of error in his experiments. In particular, various simple and indeed normal fluids, when added to the blood out of the body, would, under certain circumstances, hasten its coagulation; and in all cases in which pus, or any other abnormal agent, was thrown into the veins, inasmuch as it must come into contact with the lining membrane of the vessel, as well as with the blood, any resulting phenomena could not be legitimately referred exclusively to either. In injecting pus into the veins, moreover, the author had not been able to verify the observations of Mr. Lee; and he cited cases in which pus was injected into the femoral veins without producing any remarkable coagulation of the blood. Where such a result

did follow, Dr. Mackenzie believed that it might be accounted for on another principle than that assigned by Mr. Lee.

To ascertain the conjoint influence of the blood and irritation of the lining membrane of veins, in producing obstructive phlebitis, the jugular veins had been exposed in several dogs, and their distal branches ligatured, so as to prevent the entrance of blood. One of the distal branches was then opened, and through the opening some lint, saturated with a strong solution of nitrate of silver, was passed for some distance. The opening was then closed; and, the ligatures having been taken off the other branches, the blood was allowed to re-enter, and circulate through the vein. In each case, the blood had coagulated throughout the portion of vein which had been irritated; and, according to the date at which the examination was made, it was more or less firmly coagulated and decolorised, and the vein exhibited more or less fully the phenomena of obstructive phlebitis. Hence irritation of the lining membrane of veins could modify, in a remarkable manner, the condition of the blood; and upon this would follow all the changes constituting obstructive phlebitis. With regard to the question, whether actual inflammation of a vein was essential to the production of such coagulation of the blood, it was conclusively shown, after a lengthened inquiry, that such was not the case; for, on throwing irritants into a vein, and examining the condition of the blood and the vessels at short periods after the operation, it was found that, whilst coagulation of the blood had taken place in the track of the irritant towards the heart, and the coagulum had become adherent to the lining membrane of the vein, the latter was found, on careful examination, to be perfectly smooth, polished, and free from redness or inflammatory appearance. The author hence concluded that phlebitis was not the primary, or even an essential condition, of the pathology of venous obstruction; that mere irritation or excitation of the lining membrane of the vein would give rise to it; and that the phenomena primarily commenced in, and depended upon, a disturbance of the relations normally subsisting between the blood and the lining membrane of veins. He then proceeded to investigate how far this condition of the lining membrane might be produced by constitutional causes alone, or a general vitiation of the blood; for, although such might be inferred from the results of his previous investigations, he was unwilling to accept the fact as a matter of inference. He accordingly had performed a course of experiments, in which lactic acid, and other abnormal agents, were injected into the blood, and their effects in giving rise to obstruction of veins carefully noted. The results enabled the author to affirm the principle, that, by vitiating the general mass of the blood, not only particular veins, but even large portions of the venous system, might become obstructed, in the absence of local injury or inflammation of these vessels.

Having shown that extensive obstruction of veins was not producible by exciting local inflammation of these vessels, whilst, by vitiating the blood, large portions of the venous system might be readily irritated, obstructed, and inflamed, the author concluded that the cause of venous obstruction should rather be sought for in the blood than in inflammation of the veins. This cause, he believed, would also account for all the known phenomena of phlegmasia dolens; for regarding it as arising from the blood rather than from any local or specific affection of the veins, nerves, muscles, lymphatics, and cellular tissue of the affected extremity, we could reasonably account for the *concurrent* disturbance of all these several organs and structures, which, indeed, was an essential condition of the disease, and which, by giving rise to irritation coetaneously in them, would occasion that tense elastic swelling, loss of motor power, morbid sensibility, lesions of the lymphatics, and obstructed and inflamed condition of the veins of the limb, which together constitute the pathognomonic symptoms of the disease.

To determine how far this theory of the disease was supported by its clinical history, the author entered upon the analysis of one hundred cases of the disease, as recorded in systematic treatises or in various medical periodicals. This number comprehended sixty cases which had occurred after parturition, and forty which had occurred independently of this function. The former series comprised twenty deaths and forty recoveries; the latter an equal number of deaths and recoveries. The principal facts of these cases were carefully analysed and tabulated; but before applying them to the solution of the question under consideration, the author laid down the following principle:—That the origin of a local disease from constitutional causes might in general be deduced from two series of facts; first, its having been preceded by local or constitutional causes calculated to vitiate the blood; and, second, the simultaneous existence of

various local affections in different organs. Upon these data he tested the validity of the opinion which he had espoused on the proximate cause of phlegmasia dolens; and having shown that the more general circumstances connected with the labour, the date of attack, and the extremity affected, in the puerperal cases, supported rather than opposed this view, he entered upon an especial consideration of the principal antecedents and probable causes of these cases, their concomitant affections, and the *post mortem* lesions in fatal cases.

The analysis of their antecedents gave the following results. Of the sixty cases, thirty-five had followed upon some form of puerperal fever: thirteen upon exposure to cold, and consequent arrest of the cutaneous secretion; three upon dietetic errors, and consequent derangement of the assimilative processes; three upon the operation of epidemic influences; four had occurred in the progress of pulmonary consumption, or some other constitutional disease; two had followed quickly upon severe or protracted labour; whilst in three no particular information was given. Thus, in nearly all, the attack had been preceded by some circumstance calculated to vitiate the blood, such as fever, suppression of the natural excretions, epidemic influences, derangement of the assimilative processes, or some constitutional disease. Dr. Mackenzie then entered upon a critical examination of the *modus operandi* of these influences in giving rise to venous obstruction and inflammation, as well as to the special symptoms of phlegmasia dolens. The thirty-three cases preceded by puerperal fever were referable to two divisions, viz., those which had been attended by injury or inflammation of the uterine organs during, or subsequent to, labour, and those which had occurred from other causes. Believing the former to be typical of the operation of local causes in contaminating the blood, by furnishing unhealthy or inflammatory secretions, and so giving rise to the disease, he pointed out the several modes in which such causes may operate. In connexion with the cases which had been preceded by some form of puerperal fever, unconnected with any local injury or lesion of the uterine organs, he entered into the consideration of the peculiar circumstances under which irritation, obstruction, and inflammation of veins might occur from fever or constitutional causes, and pointed out the influence of the three following in co-operating to this result: 1, constitutional debility; 2, a redundancy of the fibrinous element of the blood; 3, an affinity between the morbid elements in the circulation and the lining membrane of the veins. He further considered under this head, the reason why the venous system should more especially suffer from constitutional causes than the arterial; and lastly, the circumstances which determined irritation and obstruction of particular veins, rather than of others. Cases which had occurred from exposure to cold, might be legitimately connected with an abnormal condition of the blood; for whenever the cutaneous functions were arrested or interrupted from this cause, material as well as dynamic changes ensued in the blood and the circulation. The analogy between such cases of phlegmasia dolens and rheumatism, moreover, afforded a strong argument in favour of their blood-origin; and lactic acid, an important constituent of the sweat, and the supposed *materies morbi* of rheumatism, had been actually detected in the blood of puerperal women, either in morbid excess, or as an abnormal agent. Errors of diet, and derangement of the assimilative processes, were shown to be productive of a morbid condition of the blood, both by giving rise to a crude, unassimilable matter, which, on entering the blood-vessels, might prove a source of irritation to the system; and also by producing sympathetic fever, which would tend to impede or arrest the excretory functions. In treating of the cases which followed upon the operation of epidemic influences, the author more particularly spoke of the erysipelatous poison, and showed that whilst its primary action was upon the blood, its secondary might be upon the lining membrane of veins, just as it had been shown to be upon the skin and cellular tissue. The cases following upon pulmonary consumption, and other constitutional disease, needed no particular remark—they were clearly referable to an abnormal condition of the blood. Thus, in fifty-seven out of the sixty puerperal cases, the attack had been preceded by causes calculated to produce a vitiation or impurity of the blood; and with regard to the three remaining, of which no antecedent history was given, coexistent lesions were found in other parts of the body. On investigating the concomitant affections met with in these cases, it was found that in forty-five out of the sixty, some evident local or constitutional malady coexisted with the local affection of the extremity. Thus, in fourteen, or in about one-fourth, there was evidence of the coexistence of some form of thoracic inflammation or disease; in fourteen, also, there were symptoms of abdominal inflammation or disease; in

nine there were cerebral symptoms; whilst in others various local affections were met with. Of the forty non-puerperal cases, ten followed upon some form of fever; eleven upon exposure to cold; three upon suppression of the catamenia; eight occurred in the progress of consumption, or some other constitutional disease, whilst seven followed upon the operation of local causes, calculated to vitiate the blood, such as suppurating wounds, malignant ulcerations, etc., which the author had shown to be capable of giving rise to a morbid condition of the blood, and thus to the phenomena of the disease. An analysis, in the last place, of the concomitant affections and *post mortem* lesions in the non-puerperal cases, showed that, with few exceptions, various local affections coexisted with the affection of the extremity; and in the fatal cases, extensive lesions were found in distant organs and structures. In concluding his investigations, the author observed that the results of clinical experience thus harmonized with those of physiological research; and he finally proceeded to lay down the general principles upon which he conceived the treatment of the disease should be conducted.

A discussion of considerable interest followed the reading of Dr. Mackenzie's very able paper. The speakers were Mr. Henry Lee, Mr. Arnott, Mr. Hodgson, Dr. Copland, and Dr. Locock. As many of their remarks evidently proceeded from an imperfect impression of the scope of the paper, we have thought it best upon the whole entirely to omit the speeches referred to, as well as the author's reply. By following this course, we have been enabled to publish so clear and full an abstract of the paper as will enable our readers to arrive at their own conclusions. Papers like that of Dr. Mackenzie's are too elaborate in their details, and contain too much new matter, to be advantageously subjected to extemporaneous discussion.

TUESDAY, MARCH 22nd, 1853.

JAMES COPLAND, M.D., President, in the chair.

CASE OF GANGRENA SENILIS TREATED SUCCESSFULLY BY AMPUTATION OF THE THIGH HIGH UP. BY T. W. GARLIKE, ESQ.

The patient was a man aged 60, who was the subject of senile gangrene in the right foot. After the disease had progressed some time, a distinct line of demarcation was set up; and formations of matter took place in the leg, producing much distress, which diminished as they subsided. The temporary improvement was followed by an aggravation of the local and constitutional symptoms, and suppuration occurred in the knee-joint. After this, however, as there were evidently renewed attempts of nature to repair the injury, and the patient was importunate to have an operation performed, Mr. Garlike amputated the thigh as high up as possible. The femoral artery was found ossified through two-thirds of its calibre, at the line of section: the profunda was in the same condition. The tube of the femoral stuck out an inch on retraction of the muscles, and the small arteries felt like wire. Not much blood was lost during the operation. The patient made a favourable progress, had a good stump, and regained appetite and flesh. At the end of two months, a ligature was found remaining; and many weeks after, an annulus of bone exfoliated. Fifteen months have elapsed since the operation was performed; and the man continues in good health, except that the left lower limb presents indications of obstructed arterial circulation. The author thought that country air had given to his patient an advantage which hospital patients could not possess.

Mr. ADAMS (of the London Hospital) mentioned corroborative cases. He believed that very many more had occurred than had been recorded. This form of gangrene was by no means limited to persons advanced in life.

Professor FERGUSON said, that it was well for the surgeon to know those precepts of his art which had been formed out of the accumulated experience of his predecessors, and it was right to be generally guided by them in his practice; but it was equally important that he should be able to appreciate exceptional cases, and know when he might be most likely to benefit his patient by a deviation from the common path. He thought that success in Mr. Garlike's case depended upon exceptional treatment having been judiciously applied in an exceptional case; and that a favourable result in a few such cases was not enough to unsettle the established principle, that interference with the knife in gangrena senilis was generally wrong, and that it was most prudent to let nature do her best. Possibly, by amputating high up, the danger of sloughing flaps was lessened. Gangrena senilis was an objectionable term, and was often applied to cases etiologically distinct.

Mr. ARNOTT disliked the term *gangræna senilis*, as it led the mind away from the true nature of the disease. That dry and mummified condition of a part which resulted from obstructed circulation in it, might more appropriately be called *spontaneous gangrene*. It certainly was not an affection peculiar to old age, as was shown by the testimony of many authors: and this very condition had occurred in a child three years and a half old, who had recovered under the use of opiates and calomel in his hands; and the case had been described by Mr. Solly. Mr. Arnott had never seen a case of arteritis, but he did not mean to deny that there really was such a disease.

Mr. H. B. NORMAN thought that there were some circumstances in the case which removed it from the category of cases of senile or spontaneous gangrene. There was, for example, a sthenic inflammation of the knee-joint.

PRACTICABILITY OF ASCERTAINING THE PERMEABILITY OF THE EUSTACHIAN TUBE WITHOUT THE AID OF THE CATHETER. BY JOSEPH TOYNBEE, ESQ., F.R.S.

The method referred to by Mr. TOYNBEE, was the performance of the experiment described in the abstract of his paper read before the Royal Society, given at p. 177 of our number for February 25th. He objected to the use of the Eustachian catheter; first, on account of the uncomfortable sensations which it produced; secondly, on account of the difficulty of applying it. Its use was to be discouraged in obstruction of the Eustachian tube from thickening; but in those more rare cases, where a plug of mucus obstructed the canal, it might be useful. The absence of the sensation produced by swallowing with the mouth and nostrils closed, or of the sound heard with the auroscope, might indicate obstruction from adhesion of the lips of the tube from mucus, or from a mucous plug, or from (more rarely) permanent obstruction.

The Society then adjourned to Tuesday, the 12th of April, when it is expected that a paper by Professor Syme, of Edinburgh, on the "Treatment of Stricture", will be read.

ASSOCIATION INTELLIGENCE.

MEDICAL REFORM BILL:—DEPUTATION TO LORD PALMERSTON.

On Friday the 18th of March, a deputation of the Provincial Medical and Surgical Association waited, by appointment, upon Lord Palmerston, at his residence in Carlton Gardens, to present to his Lordship the Bill that they have prepared for the regulation of the medical profession, and to request him to introduce it into Parliament as a Government measure.

The deputation consisted of Sir Charles Hastings, M.D., D.C.L., President of the Council; A. Robertson, M.D., of Northampton; Geo. Webster, M.D., of Dulwich; Mr. Noble, of Manchester; Mr. Southam, of Manchester; Mr. Cartwright, of Oswestry; Mr. Bree, of Stowmarket; Mr. Bottomley, of Croydon; Mr. Stedman, of Guildford; Mr. Walsh, of Worcester; Mr. Nunneley, of Leeds; Mr. Hastings, Barrister—being the Committee of the Association who have charge of the bill; John Forbes, M.D., President of the Metropolitan Counties' Branch; J. C. Williams, M.D., Nottingham, President of the Midland Counties' Branch; C. Chadwick, M.D., Leeds, President of the Yorkshire Branch; J. Beddingfield, M.D., Needham Market, President of the Suffolk Branch; J. Heygate, M.D., Derby; Mr. Norman, Bath; F. R. Horner, M.D., Hull; G. S. Jenks, M.D., Brighton, Vice-Presidents of the Association; J. Conolly, M.D., Hanwell; C. Cowan, M.D., Reading; W. P. Brookes, M.D., Cheltenham; Mr. Nunn, Colchester; Mr. Clements, Shrewsbury; H. Johnson, M.D., Shrewsbury; E. V. Mainwaring, M.D., Bournemouth, Members of the Council: Dr. Renton, late President of the College of Physicians of Edinburgh; Dr. Combe, President of the College of Surgeons, Edinburgh; Sir John Liddell, of the Medical Department of the Navy; and Mr. Wakley, late M.P. for Finsbury.

The following Members of Parliament accompanied the deputation. The Rt. Hon. T. B. Macaulay; the Rt. Hon. M. T. Baines; the Rt. Hon. T. M. Gibson; Lord Alfred Hervey; Lord Elmsley; Lord Hotham; Mr. O. Ricardo; Mr. Walter; Mr. Brotherton; Sir G. Pechell; Sir T. Winnington; Capt. Rushout; Mr. Laslett; Mr. B. Westhead; Sir H. Willoughby; Mr. W. Knight; Mr. Crawford; Hon. R. H. Clive; Mr. Cobden; Sir G. Goodman; Mr. Bright; Hon. Capt. Duncombe; Mr. Alcock;

Mr. Pigott; Mr. Phinn; Mr. Langton; Mr. Raikes Currie; Mr. Booker; Mr. Aglionby; Mr. Tomline; Mr. Whalley; Mr. C. Berkeley; Mr. G. Berkeley; Mr. Brown; Mr. Martin; Mr. Price; Mr. Headlam; Mr. Cobbett; Mr. Bass; Mr. Drummond; Mr. Mangles; Mr. Bell; Mr. Stafford; Viscount Newark; Mr. Barrow; Mr. Vernon; etc.

The deputation having been courteously received by Lord Palmerston,

Sir CHARLES HASTINGS addressed his Lordship on their behalf, and said that the Provincial Medical and Surgical Association had existed for twenty-one years, and numbered nearly two thousand members, residing in all parts of the kingdom. It was established for the advancement of medical science; but, finding many obstacles from the incongruous state of the profession, they had found that it was absolutely necessary to improve the organization of the profession. They had, from the first, laid down broad principles of medical reform, and had never swerved from them. These were, uniformity of qualification, equal right to practise throughout the United Kingdom, and the adoption of the representative principle in the formation of the councils or other governing bodies. They had from time to time presented petitions to Parliament, and memorials to Government on the subject; and, within the last three years, Sir G. Grey had expressed a resolution to give his sanction to any measure that might be generally approved of by the medical profession. Since that time a Committee of the Association had framed a bill with the assistance of Mr. Hastings, a barrister, which had been repeatedly submitted to the profession, through the medical societies, and the district branches; and it had been altered and improved to meet various suggestions. As the result of their labours, he might now state that the bill had received an unparalleled amount of support. The London College of Physicians had given it their approval, and declared that it was in harmony with their proposed new charter. A deputation from the Edinburgh Colleges was present to express their approval: and it was warmly supported by a vast majority of medical practitioners throughout the kingdom. In fact, no opposition had been made to its principles, though some exceptions might have been taken to its details. The bill embraced the establishment of a Medical Council, of a Board of Examiners before whom every candidate for a right to practise must go, and of a system of registration. Sir Charles then expressed the wish of the Committee, that, should any objections be made to the measure, his Lordship would give them an opportunity of replying through their secretary, Mr. Hastings; and in placing the bill in his Lordship's hands, he trusted that he would think fit to pass it into law, and thus to confer a great benefit, not only on the medical profession, but on the sick and suffering of the whole community.

Dr. RENTON, and Dr. COMBE, on behalf of the medical Colleges of Edinburgh, then expressed their perfect approval of the bill.

Sir JOHN LIDDELL pointed out the need of better education for medical officers in the navy; at present they had men well versed in surgery, but ignorant of pharmacy, and *vice versa*. The establishment of a common Board of Examination would remedy this evil.

Mr. WAKLEY then addressed his Lordship, and said that he had been engaged for twenty-nine years in the work of medical reform, but never till now had he seen much hope of a successful result. Various measures had been introduced into Parliament by Sir James Graham, and by himself, but they had all failed. Now, however, there was a very great approach to unanimity on the subject; and if Lord Palmerston took up the bill as a Government measure, which he implored him to do, it would receive the most powerful support, it would pass into law without any serious opposition, and would be productive of incalculable good.

Dr. WEBSTER, as an old medical reformer, and one supposed to take rather extreme views, begged to express his entire concurrence in the bill.

Mr. BRADY, M.P., and several other gentlemen having spoken to the same effect,

Lord PALMERSTON said that he was deeply impressed with the subject which had been brought before his notice by the deputation, affecting, as it did, not only the interests of the public, but those of a most highly educated and important profession. Many attempts had been made to legislate on it, but without success. When out of office, some years since, he had been requested to take up the subject, but had declined to do so, on account of the discordant opinions then entertained by the medical profession. Now, however, a different feeling seemed to prevail, and a great approach towards unanimity had

evidently been made, as was manifest from the importance and varied character of the deputation. He should give his best attention to the measure that had been laid before him; and if there was a good prospect of bringing it to a satisfactory settlement—and he thought he saw, now, such an opportunity—he should feel it his duty to bring it before Parliament, in conjunction with his colleagues, as a Government measure, and to carry it out with energy. His Lordship added that he should take an early opportunity of communicating with the secretary, Mr. Hastings, on the subject.

Sir CHARLES HASTINGS thanked his Lordship, on behalf of the deputation, for his personal courtesy, and for his promise to take the Bill into his favourable consideration.

The deputation then withdrew.

EDITOR'S LETTER BOX.

MEDICAL REFORM BILL.

LETTER FROM THE SECRETARY OF THE COMMITTEE TO THE EDITOR.

SIR,—As Secretary to the Committee of the Association, appointed at the anniversary meeting held at Oxford in July last, "to consider the Draft Bill prepared by the Central Council", I am anxious to announce to the members of the Association, through the medium of your columns, what have been the proceedings of the Committee up to this time, and what is the present position of affairs in regard to the Bill.

Shortly after their appointment, the Committee proceeded to give their best attention to the measure that had been committed to their charge; and, although scattered over the length and breadth of England, have held various meetings for the purpose of discussion, and have corresponded with me, and with each other, on the subject. One of the first resolutions at which they arrived was, that the measure ought, if possible, to be one for the whole of the United Kingdom; and in pursuance of this determination, they appointed Mr. Nunneley, of Leeds, and myself, as a deputation to confer with the Scotch medical bodies. I am happy to say that our visit to Edinburgh was attended with the happiest results; that the Edinburgh Colleges agreed to the Bill, under certain very reasonable conditions, and that they have since afforded to the Committee a zealous and valuable support. We have also negotiated with the London Colleges of Physicians and Surgeons, and have received from the former an approval of the measure, given upon certain conditions, but in a liberal and disinterested spirit.

The Committee have also reason to believe that an alteration in the Bill, which would not affect its principle, nor diminish, in their opinion, its practical efficiency, would remove any objection which the College of Surgeons may have entertained towards it.

The Committee came a short time since to the resolution that, as the principles of the Bill met with no opposition, and as the objections made all referred, more or less, to matters of detail, they would obtain an earlier solution of these minor difficulties, and thus better fulfil the trust confided to them, by submitting the measure to Lord Palmerston at once, and leaving the arrangement of these details to his Lordship's discretion.

Accordingly, on Friday, the 18th inst., the Committee, accompanied by a deputation from the Scottish Colleges, by a number of medical men from all parts of the kingdom, and by nearly sixty members of Parliament, waited upon Lord Palmerston, by appointment, and placed the Bill in his hands, with an earnest entreaty that he would take it into his favourable consideration.

As you will probably give an account of the interview in your columns, I need only say, that the answer given by his Lordship was one of the most satisfactory nature, and that he promised to communicate with me shortly upon the subject.

Until his Lordship's decision be known, it would be manifestly improper for me to enter into any more detailed explanation of the former proceedings of the Committee; nor would I advise any immediate movement in the Association in favour of the Bill.

The Committee have appointed a sub-Committee, charged with the duty of making preparations for a vigorous agitation in favour of the measure, as soon as it shall be laid on the table of the House; and their experience in the last fortnight has proved to them, that the amount of parliamentary influence

which they can bring to bear, is beyond their most sanguine expectations.

There can, therefore, be no doubt of ultimate success; and I trust that, before the close of the Session, I may be able to congratulate the members of the Association on their having definitely settled the question of medical reform.

I am, etc.,

G. W. HASTINGS.

Oxford Circuit, Shrewsbury, March 21st, 1853.

NEWS AND TOPICS OF THE DAY.

LORD LYTTLETON'S BILL, INTITULED "AN ACT FURTHER TO EXTEND & MAKE COMPULSORY THE PRACTICE OF VACCINATION".

WHEREAS an act was passed in the fourth year of the reign of Her present Majesty, intituled "An Act to extend the Practice of Vaccination": and whereas an act was passed in the fifth year of the same reign, intituled "An Act to amend an Act to extend the Practice of Vaccination": and whereas it is expedient that the practice of vaccination should be still further extended: Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

I. The father or mother of every child born in England or Wales after the first day of August in the year of our Lord one thousand eight hundred and fifty-three shall, within six calendar months after the birth of the said child, or in the event of the death, illness, absence, or inability of the father and mother, then the person who shall have the care, nurture, or custody of the said child, shall, within seven calendar months after the birth of such child, take, or cause to be taken, the said child to the medical officer or practitioner appointed according to the provisions of the first-recited act, or to some other duly qualified practitioner, for the purpose of being vaccinated; and the said medical officer or practitioner shall, and he is hereby required, thereupon, or as soon after as it may conveniently and properly be done, to vaccinate the said child, without fee or reward other than is provided for by the said recited acts.

II. Upon the successful vaccination of any child, the medical officer or practitioner who shall have performed the operation, shall (without fee or reward) deliver to the father or mother of the said child, or to the person who shall have the care, nurture, or custody of the said child, a certificate under his hand, according to the form of schedule herein-after inserted, marked (A.), that the said child has been successfully vaccinated; and such certificate shall, without further proof, be admissible as evidence of the successful vaccination of such child, in any information or complaint which shall be brought against the father or mother of the said child, or against the person who shall have had the care, nurture, or custody of such child, as aforesaid.

III. If such medical officer or practitioner be of opinion that any child which shall be brought to him for vaccination, is not, at the time when so brought for the purpose aforesaid, in a fit and proper state to be successfully vaccinated, he shall postpone the vaccination until such time as he thinks the operation may be safely and successfully performed; and he shall, in the event of such postponement, thereupon and immediately deliver, without fee or reward, to the father or mother of such child, or the person having the care, nurture, or custody of the said child, a certificate under his hand, according to the form of schedule herein-after inserted, marked (B.), that the child is in an unfit state for successful vaccination; and such certificate shall remain in force for three calendar months from its delivery as aforesaid; and the father or mother of the said child, or the person having the care, nurture, or custody of the said child, shall, within three months next after the delivery of the said certificate as aforesaid, and if the said child be not vaccinated at or by the termination of such period of three months, then, during each succeeding period of three calendar months until such child has been successfully vaccinated, take, or cause to be taken, to the said medical officer or practitioner, such child, to be vaccinated by him; and if the said medical officer or practitioner deem the said child to be then in a fit and proper state for successful vaccination, he shall forthwith vaccinate it accordingly, and shall, without fee or reward, deliver to the father or mother of such child, or person having the care,

nurture, or custody of such child, a certificate under his hand, according to the form of schedule herein-after inserted, marked (A), that such child has been successfully vaccinated; but if the said medical officer or practitioner be of opinion that the child is still in an unfit state for successful vaccination, then he shall again deliver to the father or mother of such child, or person having the care, nurture, or custody of the said child, a certificate under his hand, according to the said form of schedule (B.), that the child is still in an unfit state for successful vaccination; and the said medical officer or practitioner, so long as such child remain in an unfit state for vaccination, and unvaccinated, shall, at the expiration of every succeeding period of three calendar months, deliver, if required, to the said father or mother of such child, or person having the care, nurture, or custody of such child, a fresh certificate under his hand, according to the said form of schedule.

iv. The guardians or overseers of the several unions or parishes in which the operation has been performed, shall keep a register of the persons so reported by the said medical officer or practitioner as having been successfully vaccinated; and such register shall be under the care and control of some person appointed by them for that purpose, who shall, at all reasonable times, allow searches to be made of any such register book in his keeping, and shall give a copy, certified under his hand, of any entry or entries in the same, on payment of the fee herein-after mentioned; (that is to say,) for every search extending over a period of not more than six months, one shilling, and one shilling and sixpence for every additional year, and the sum of sixpence for every single certificate.

v. The registrar of births and deaths in every union, parish, or district, shall, on the birth of any child within that union or parish, give notice in writing, according to the form of schedule herein-after inserted, marked (c), to the father or mother of such child, or in the event of the death, illness, absence, or inability from sickness or otherwise, of the father and mother, then to the person upon whom the care, nurture, or custody of such child shall have devolved, that it is the duty of such father or mother, or person having the care, nurture, or custody of such child as aforesaid, to take care that the said child shall be vaccinated in the manner directed by this act; and if, after such notice, the father or mother of the said child, or the person so having, as aforesaid, the care, nurture, or custody of the said child, shall not accordingly cause such child to be vaccinated, then such father or mother, or person having the care, nurture, or custody of such child as aforesaid, so offending, shall forfeit a sum not exceeding two pounds.

vi. A fee of one penny shall be paid to such registrar for the performance of such duty; and he shall keep a book, to be provided by the guardians or overseers, containing a minute of his having duly given such notice; and the said fee shall be payable in the same manner as the fee now payable to such registrar for registering the birth of such child as aforesaid is paid.

vii. That in the event of a child becoming sick or indisposed, in consequence of having been vaccinated as aforesaid, then and in such case, it shall be the duty of the medical officer and practitioner who vaccinated the said child to attend upon and prescribe for the said child during such sickness or indisposition, and to furnish it with such medicines as may be necessary for its recovery, without fee or reward, other than is provided for by the above first-mentioned act.

viii. If any child be born out of England and Wales, that then the father or mother of such child, or person having the care, nurture, or custody of the said child, shall, within two months after the arrival of the said child in England or Wales, under a penalty of forty shillings, to be recovered under the provisions of this act, cause the said child to be vaccinated by such medical officer or other qualified practitioner as aforesaid, subject to the provisions hereinbefore contained in relation to children born in England.

ix. All penalties by this act imposed shall be recovered before any two justices of the peace for the county, city, or place where the offence shall have happened, upon the information or complaint of any person; and if, on the conviction of the offender, such penalties, with the costs of conviction, shall not forthwith be paid, the same shall be levied by distress and sale of the goods and chattels of the offender, by warrant under the hand and seal of such justices; and for want of distress, such justices may commit every such offender to the common gaol or house of correction for the county, city, or place where the offender shall be committed, without bail or mainprize, for any term not exceeding one calendar month, unless such penalty, and all reasonable charges attending the recovery thereof, shall be sooner paid.

Schedules referred to by this Act.

SCHEDULE (A).

I, the undersigned, hereby certify, that _____, the child of _____, aged _____, of the parish of _____, in the county of _____ has been successfully vaccinated by me.

Dated this _____ day of _____, 185 _____.

(Signed) A.B.

Surgeon to the Union or Parish (as the case may be).

SCHEDULE (B).

I, the undersigned, hereby certify, that I am of opinion that _____, the child of _____, of the parish of _____, in the county of _____, aged _____, is not now in a fit, and proper state to be successfully vaccinated, and I do hereby postpone the vaccination until the _____ day of _____.

Dated this _____ day of _____, 185 _____.

(Signed) A.B.

Surgeon of the Union or Parish (as the case may be).

SCHEDULE (C).

I, the undersigned, hereby give you notice, and require you to have C.D. vaccinated within six months after the birth, or within three months after your having the guardianship of the said C.D., and the said C.D. shall be six months old, pursuant to the Provisions and Directions of the Act of the 16 Victoria, cap. _____. As witness my hand this _____ day of _____, 185 _____.

J.B.

Registrar of Births and Deaths for the _____ Union or Parish (as the case may be).

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

*FRASER, Patrick, M.D., elected Physician to the London Hospital, in the room of the late Dr. Pereira.

GUTHRIE, C. Gardiner, Esq., elected Surgeon to Westminster Hospital.

HOLTHOUSE, Carsten, Esq., appointed Assistant-Surgeon to the Westminster Hospital.

MILLER, James, M.D., appointed, on March 21st, Assistant-Physician to the London Hospital, in the room of Dr. Fraser.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

GRAVES, Robert James, M.D., at his residence, Merrion Square, Dublin, on the 20th instant, after a protracted illness, aged 56. Dr. Graves was one of the most eminent physicians of Dublin; and had a world-wide fame. His writings tended much to advance practical medicine; and we believe that to him the Dublin School of Medicine was chiefly indebted for the introduction and development of clinical teaching, before it was generally instituted in London, in accordance with that plan which at an earlier period raised the University of Edinburgh to so high a degree of celebrity under its Cullens and its Gregorys.

NIXON, Robert Law, M.D., at Grenville Street, Dublin, on the 15th instant.

ORFILA, M., in Paris, on March 12th, aged 70.

OVERWEG, Dr., one of the travellers employed in determining the boundaries of Lake Tsad, in Africa, lately.

SWEENEY, Daniel, M.D., on the 11th instant, at Cork.

BOOKS RECEIVED.

[*An asterisk is prefixed to the names of Members of the Association.]

BRINTON, William, M.D. DR. G. VALENTIN'S PHYSIOLOGY. Part I, 8vo., pp. 320. Illustrations on Wood, Copper, and Stone. London: 1853.

COULSON, William. LITHOTOMY AND LITHOTRITY. pp. 388. London: 1853.

WIBLIN, John, Esq., and *HARVEY, Alexander, M.D. ACCOUNT OF YELLOW FEVER, as it occurred on board the R.M.S. ship *La Plata*, in November 1852. London: 1853.

*BENNETT, James Henry, M.D. INFLAMMATION OF THE UTERUS, its Cervix and Appendages, and on its Connexion with Uterine Disease. Third edition. 8vo., pp. 532. London: 1853.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London; or to the office of the Journal.

Apothecaries' Hall.—The Next Preliminary Examination in CLASSICS and MATHEMATICS will take place on TUESDAY, JULY 19. Gentlemen who intend to present themselves are requested to give notice on or before June 20. The Classical subjects are:—The Gospel of St. Mark in Greek; the 1st Book of Homer's Iliad; the 1st Book of Virgil's Georgics; the 1st Oration of Cicero against Catiline.

The Classical subjects for the year 1883-84 will be:—The Twelve First Chapters of the Acts of the Apostles in Greek; the 2nd Book of Homer's Iliad; the Catiline War, by Sallust; the 2nd Book of Virgil's Aeneid.

This day, in 8vo, cloth, price 5s., with 20 Diagrams on Wood, and 2 Plates.

On the Construction and Use of the Microscope.

By ADOLPHE HANNOVER, M.D., Lecturer on Anatomy in the University of Copenhagen. Edited by JOHN GOODSIR, F.R.S.E., Professor of Anatomy in the University of Edinburgh.

CONTENTS.—Preliminary Remarks.—On the Simple Microscope.—On the Construction of the Dioptric Compound Microscope.—Directions for the Use of the Dioptric Compound Microscope.—On the Solar Lamp, Oxhydrogen, and Photo-Electric Microscope.—Of the Catoptric Compound Microscope.

SUTHERLAND & KNOX, Edinburgh; SIMPKIN, MARSHALL & Co., London.

Board and Education for Children.

—A Lady residing near London, and moving in good society, is desirous of RECEIVING into her family TWO or THREE CHILDREN, orphans, or whose parents may be abroad. Every social and educational advantage along with a mother's care. Terms: (including everything), £125 for one; £225 for two; and £300 for three. Apply, by letter only, to Mrs. R. F., Association Medical Journal office, 37, Great Queen-street, Lincoln's Inn Fields, London.

Edinburgh Graduates.—It is proposed to form a Committee of EDINBURGH GRADUATES, for the purpose of watching over their interests in connexion with rumoured measures of University Reform, and the Parliamentary Representation of Universities. A preliminary Meeting will be held after Easter. Gentlemen desirous of attending, are requested to communicate, by letter, with EDINBURGH, 37, Great Queen Street, Lincoln's Inn Fields, London.

TO SURGEONS, DISPENSING CHEMISTS, ETC.

Sulphate of Quinine, pure Crystallized, prepared by EDWARD HERRING, for the use of Hospitals, Dispensaries, Surgeons, Dispensing Chemists, etc.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its purity and great reduction in price are now attracting the attention of Medical Men and Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, capsuled with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London, and the United Kingdom, and in quantities of not less than 100 ounces of

JACOB HULLE, Jun., Proprietor, Chemical Works, Trinity Street, Southwark, London.

Householders' Life Assurance Company.

The Directors adopt the principle in all cases of paying the Medical Referees.

DIRECTORS.

Wm. Ashton, Esq., Horton House, Colnbrooke.
The Rev. T. Cator, Bryanstone-square, and Skelbrook-park, Doncaster.
Charles Hulse, Esq., Hurst, near Reading.
Francis Davenport Bullock Webster, Esq., 49, New Bond-street.
Richard Griffiths Walford, Esq., 2, New-square, Lincoln's Inn.
Peter Paterson, Esq., Leyton, Essex.
Thomas Pocock, Esq., Southwark-bridge-road.
Peter Paterson, Esq., jun., Park-road, Holloway.

DISTINCTIVE AND PECULIAR FEATURES.

1. Every Policy is absolutely indisputable, the state of health, age, and interest being admitted on the Policy.
2. The Savings Bank Assurance—the Company granting an Assurance on the life of the Depositor for every sum deposited, with liberty to withdraw the deposit at fourteen days notice.
3. Loans on the security, or for the purchase, or erection, of property, on an entirely new plan, the payments to cease in the event of the death of the Borrower, and the property to be handed over to his family, or representatives, free and unencumbered.
4. The Savings Bank and Assurance-Loan Branches combined, by which Depositors in Savings Banks and intending Members of Building Societies, may invest their funds so as to secure the Assurance of a given sum in the event of death, and at the same time employ them for the purchase of property during life. This system supersedes Building Societies—supersedes Savings Banks.

RICHARD HODSON, Secretary.

OFFICES,—15 & 16, Adam-street, Adelphi, London.

Dispensary, Newark-upon-Trent.

NOTES.—HOUSE-SURGEON WANTED. He must be a Member of the Royal College of Surgeons of England and a Licentiate of the Apothecaries' Company, and will be expected to fill the appointment for two years. Salary, £100 per annum, with Furnished Apartments attached to the Institution, coals, candles, and attendance. Testimonials to be addressed to the Secretary, Dispensary, Newark-upon-Trent, on or before April 1st. The Election to take place on the 2nd of April, and the duties to commence on Friday, the 8th of April next.

For Varicose Veins and Weakness.

—SURGICAL ELASTIC STOCKINGS and KNEE-CAPS, pervious, light in texture, and inexpensive, yielding a permanent, efficient, and unvarying support, without the trouble of lacing. Likewise, a strong low-priced article for Hospitals and the Working-classes, ELASTIC NET CORSETS of the same beautiful fabric. ABDOMINAL SUPPORTING BELTS for both Sexes; those for Ladies' use, before and after accouchement, are admirably adapted for giving adequate support with extreme lightness—a point little attended to in the comparatively clumsy contrivances and fabrics hitherto employed.

Instructions for measurement and prices on application and the articles sent by post from the Manufacturers, POPE and PLANTE, 4 Waterloo-place, Pall Mall.

The Profession, Trade, and Hospitals supplied.

Surgical Instruments, and every

Implement necessary for Surgeons can be had (warranted best quality and moderate prices) retail, as well as wholesale, from the Manufacturer, JAMES ARNOLD, Surgical Instrument Maker to St. Bartholomew's Hospital, 35, West Smithfield, London.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XIII.

LONDON: FRIDAY EVENING, APRIL 1, 1853.

NEW SERIES.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London; or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

THE EDITOR attends at the office, 37, Great Queen Street, Lincoln's Inn Fields, on Wednesdays, from 4 to 5 P.M., when not unavoidably prevented by other duties.

ADVERTISEMENTS, letters regarding the ALTERATION OF ADDRESSES, and all communications regarding the COMMERCIAL DEPARTMENT, ought to be addressed to the Publisher, Mr. THOMAS JOHN HONEYMAN, and not to the Editor.

THE RELATIONS OF MEDICAL CORPORATIONS AND MEDICAL SOCIETIES TO THE MEDICAL PROFESSION.

IN our former article on the relative position of the College of Surgeons and the profession, we were engaged in the delicate and certainly distasteful task of examining into the *ways and means* of that learned body, and the influence which dire necessity has exercised in checking the progress of medical education. We now propose to call the attention of our readers to a different view of the same subject; and, as our present purpose is to deal mainly with the position and fortunes of the profession at large, we do not feel ourselves trammelled by that natural reserve which attaches to the minds of those who are called upon to question the policy or to condemn the acts of corporate bodies.

We stated that there was felt to be "a want of harmony between the Council of the College of Surgeons of England, and those whom they nominally represent". Now, we are desirous of showing upon what grounds we have ventured to assert that the representation is *nominal*, not real; and, since we are convinced that much misapprehension exists on this head, we shall make no apology for entering fully into the subject.

First let us ask, Has the medical profession, as a profession, a real existence? that is, Are those conditions fulfilled within it which are considered essential to the permanence of all social states? Without taking the pains to demonstrate at length what those conditions are, we at once answer, that the profession of medicine is a *reality*; and it is sufficient for our purpose to declare that its existence is manifested in *practice*. If, then, practice is the life of medicine, so to speak, those who practise are the *real representatives* of the art; for let it be remembered, that the early discipline by which the student is compelled to concentrate the energies of his mind on the one end before him, and the feeling of allegiance to established truths, and even time-honoured theories, which confirm his belief in the fundamental principles of his profession, only prepare him for the active ministrations of his calling. The sick-room is the field of his duties; and, as it is in the sick-room alone that the reality of what he is doing can be seen, so is it evident that all antecedent or collateral means can only be re-

garded as tributary streams to the great ocean of usefulness.

But it may then be inquired, Does the College of Surgeons take no part in forming the character of those who are to practise? Far be it from us to deny the honour which is due to that Corporation. The College is one of the fountains of education, the appointed, and, in many respects, the well-organised portal of surgery in this kingdom; but it is not the depository, nor, if we may use the expression, the guardian of our professional faith. We might as well call the universities of Oxford and Cambridge the representatives of the church and the bar in England, as the College of Surgeons the representative of the profession of surgery.

We are now, however, led to consider a much more intricate part of the subject, namely, to investigate the causes which have governed the actions of that collective mass which we call the general profession, and particularly to examine into those complex laws of social polity which, by insensible degrees, have given a voice to the real representatives of medicine—the practisers of the art throughout the length and breadth of the land. The operations of medical skill are universal; for, like her great antagonist, Medicine is found at the doors of all classes of the community,—

"Æquo pulsat pede pauperum tabernas
Regumque turres".—

Yet the general diffusion of this catholic spirit alone would not have produced that imperative demand for even-handed justice which is now heard out of the mouths of reformers. A mightier engine has been brought to bear on medical society in common with other institutions; we allude to the formation of companies and associations, which appear to have been established chiefly for protective purposes, in consequence of the pressure from without of circumstances hostile to the well-being of the community concerned.

Now, here we may see exemplified a character which belongs in a peculiar degree to the constitution of human nature—namely, a tendency to change, not only the manners and customs of individuals, but the whole face of society itself; and, adopting the language of a profound thinker, we may go on to affirm, that "the principal cause of this peculiarity is the extensive and constant reaction of the effects upon their causes. The circumstances in which mankind are placed, operating according to their own laws and to the laws of human nature, form the characters of the men; but the men, in their turn, mould and shape the circumstances for themselves, and for those who come after them."* Let us now see how this reciprocal action has affected, and is still likely to affect, the medical commonwealth.

The first effect of the operation of the laws of the particular circumstances, is the establishment of associations and

* Mill's Logic, vol. ii, p. 503.

separate societies. At present, however, associations and societies react on the circumstances which have called them into existence, and two prominent results immediately follow this reaction: first, the overwhelming force of a confederation of men who are crying out for justice for themselves or for the liberties of science; and second, the levelling property which particularly belongs to what may be called the domestic companies of medical men. In our associations and societies, now so general throughout Great Britain, every man finds his place—birth, fortune, success in practice, or collegiate titles, all fail alike to secure for their possessors any particular deference. A man is esteemed for the qualities of his mind, and is listened to in proportion as he can bring those qualities to bear on the subject under discussion. A well-informed apothecary will rank in the estimation of his brother associates, and, therefore, eventually in public opinion, before an illiterate Fellow of a College; and the highly educated and accomplished village doctor will surpass the fashionable physician of superficial acquirements and powerful connexions.

The development of an aristocracy of merit within our ranks is, we think, an evidence that the reaction of such effects on their causes is producing not only progress but improvement.

There yet remains one other phenomenon to be noticed as resulting from this correlation of the elements which compose society. It is acknowledged on all hands that a tone of sobriety and refinement has spread itself generally over the face of the profession; and we venture to suggest it as probable, that the influence which the highest principles have had on the moral taste of the medical public has arisen, in the first place, from a reciprocal vigilance on the part of the minor societies and their component members. A scoffer at religion may dare to put forth his opinions in a book, or even in a lecture; but in a debating society his indecencies would be at once checked by a general feeling of propriety.

We here for the present close our sketch of the interchange of relations which is constantly going on between individuals and congregations, and of the results which spring from it.

CAPABILITIES OF THE DISTRICT BRANCH SYSTEM.

DURING the last few weeks, the medical profession in many parts of the kingdom has been actively engaged in preparing petitions to Parliament, and adopting other measures with the view of obtaining a more just apportionment of the Income Tax. At much inconvenience, and in many instances at considerable personal sacrifice, meetings have been attended: and by this kind of intercourse, as well as by the instrumentality of the JOURNAL, a bond of co-operation has been strengthened between those who require redress of various wrongs—a bond which we trust may at last enable a united profession to achieve not only a more equitable adjustment of the Income Tax, but also the reformation of other abuses which now press upon us both from within and from without. The events of the last few weeks have shown that it was neither contentment nor indifference, which prevented the voice of the medical profession from having been long ago heard loudly protesting against the present assessment of the Income Tax: and these events have likewise shown that within our ASSOCIATION there is a

machinery by which the opinions of the profession can be elicited, through which its rights can be defended, and its complaints be made known. We are very far from asserting that the organization of the ASSOCIATION is complete in all its parts, though we think that the approximation to completeness is most wonderful, when we remember that the institution only came into existence twenty-one years ago, and that long before its creation, and during the whole period which has since elapsed, the profession has been rent asunder by distracting influences. It has been the destiny of our ASSOCIATION greatly to assist in reconciling these differences; and to teach, both by example and precept, that much may be gained by mutual concession, while no reform can be accomplished so long as each party clamours in favour of a theoretical standard of perfection, and denounces every scheme which does not harmonize with its own. If imperfections exist in our constitution, they admit of easy remedy, as circumstances may require or justify; and if the District Branch system were extended, so that all the members of the ASSOCIATION were embraced within the geographical boundaries and the defined jurisdiction of a District Branch, having its local officers and its representatives in the Executive Council of the parent ASSOCIATION, we cannot conceive, theoretically or practically, a sounder basis of organization. This organization is in accordance with the letter and the spirit of our laws: and now that our numbers are swelling so rapidly, the time is evidently approaching when the fullest effect may be given to the *thirteenth* and *fourteenth laws* of our excellent code, viz.:

13. That the District Branches be free to govern themselves as their respective members may think fit; but that the bye-laws ordaining the special government be submitted to the General Council previously to their taking effect, in order to guard against the possibility of any such bye-laws contravening the fundamental laws of the ASSOCIATION.

14. That the District Branches be empowered to present for election such of their members, as it may be deemed advantageous to the general and local interests of the ASSOCIATION to place on the General Council.

It is very evident that by making the Branch system universal, and also changing the *power of presentation for election into the right of actual election*, and restraining at the same time the numbers of those to be elected, there would be constituted, as the Council of the Association, a representative body which might with truth be regarded as a British Medical Parliament. It would likewise be in accordance with our law, custom, and tradition, that along with the representative element, the Council should contain an element of permanency. This might be attained by a limited number of our most experienced members being elected life-members of Council; and in this way the energy and freshness which springs from the representative system would be guided by the conservative caution of mature minds.

The limits of many of the Branches are at present too wide for the establishment of efficient discipline and organization; moreover, a large number of members are not attached to any of the Branch Societies. In these two defects lies our weakness: in their removal might be our strength.

As many of the new members have written to us for information regarding the operation of the Branch System, we have thought that the preceding remarks might be useful, by supplying some information regarding the *undiscovered* or latent excellencies of our constitution.

That the members of the Association who have not yet joined a Branch Society may know how to set about it, we subjoin a list of the District Branches, with their presidents and secretaries.

I. BATH AND BRISTOL BRANCH. *President*, G. Norman, Esq. *Secretaries*, J. S. Bartrum, Esq., J. Colthurst, Esq.

II. DORSETSHIRE BRANCH. *President*, Charles Cowdell, M.D. *Secretary*, Henry A. Arden, Esq.

III. EASTERN BRANCH, including Cambridge, Essex, Huntingdon, and Norfolk. *President*, ——. *Secretaries*, E. M. Murray, M.B., J. B. Pitt, Esq.

IV. LANCASHIRE AND CHESHIRE BRANCH. *President*, Robert Bickersteth, Esq. *Secretaries*, John Hatton, Esq., Ellis Jones, Esq.

V. METROPOLITAN COUNTIES' BRANCH. *President*, John Forbes, M.D. *Secretary*, T. Ogier Ward, M.D.

VI. MIDLAND COUNTIES' BRANCH. *President*, J. C. Williams, M.D. *Secretaries*, Henry Goode, M.D., T. W. Fearn, Esq., Jos. White, Esq., J. Barclay, M.D., T. C. Simpson, Esq.

VII. NORTH WALES BRANCH. *President*, Ed. T. Hughes, M.D. *Secretaries*, Ed. Williams, M.D., D. K. Jones, Esq.

VIII. SHROPSHIRE BRANCH. *President*, Robert Broughton, Esq. *Secretaries*, Thomas J. Drury, M.D., John Robert Humphreys, Esq.

IX. SOUTH EASTERN BRANCH. *President*, ——. *Secretary*, Peter Martin, Esq.

X. SOUTH WESTERN BRANCH. *President*, P. C. De la Garde, Esq. *Secretary*, William Dashwood Kingdon, M.D.

XI. SOUTH WALES BRANCH. *President*, George Gwynne Bird, M.D. *Secretary*, W. H. Michael, Esq.

XII. SUFFOLK BRANCH. *President*, James Bedingfield, M.D. *Secretary*, W. P. Kirkman, M.D.

XIII. WEST SOMERSET BRANCH. *President*, S. F. Bridge, Esq. *Secretary*, F. H. Woodforde, M.D.

XIV. YORKSHIRE BRANCH. *President*, Charles Chadwick, M.D. *Secretary*, William Materson, Esq.

This list shows that the greater part of the north of England, and the whole of Scotland and Ireland, are without Branch Societies. As our numbers are as yet few in Ireland, we cannot in the mean time hope to see Branch Societies established there: but in the north of England, such towns as Newcastle and Carlisle might become influential centres; and in Scotland several District Branches might without difficulty be erected. For instance, the districts with the most convenient means of access to Inverness, Aberdeen, St. Andrew's, Edinburgh, Glasgow, and Dumfries, might be joined together for the purpose of forming Branches; each of the proposed Branches having respectively as head-quarters one of the leading towns just enumerated.

THE INCOME-TAX.

IN consequence of a communication from the Metropolitan Counties Branch, made to Dr. Malden through Dr. Cormack, the former gentleman consulted the Central Council at Worcester as to the expediency of a deputation from the whole Association waiting upon the Chancellor of the Exchequer. The Central Council are of opinion that such a course is not expedient. They likewise express a desire that the members of the Association be again urged to sign petitions similar to those which have emanated from Worcester and other places. At Leeds, Dr. Chadwick, by means of a circular, obtained about sixty signatures to the same form of petition as that which we printed at p. 219.

ORIGINAL COMMUNICATIONS.

VACCINE LYMPH.

By J. A. HINGESTON, Esq., Surgeon.

(Read before the Brighton and Sussex Medico-Chirurgical Society, March 3rd, 1853.)

WHEN Jenner broached his opinions concerning Vaccination, in 1798, his idea was by no means a new one. It took most of his countrymen by surprise, and, for the time, provoked against himself the most unfounded suspicions. But a ray of light had already dawned upon this obscure subject: for, as early as 1770, nearly thirty years previously, his Majesty, George the Third, had directed the attention of his Parliament to this point in a speech from the throne, in which he mentioned with deep concern the spreading of a fatal disease of an eruptive character among the horned cattle; and it appears, from the debates which arose on this curious political topic, that the previous existence of the disease was not unknown to some of the members of the House of Commons. Indeed, it had been observed in this country as far back as 1745; and its ravages continued as late as 1780. It was known, likewise, that the same eruptive disease had infested distant parts of Europe; and that in 1711, between eighty and ninety years before Jenner appeared on the field, a pustular disease of this description had broken out in Italy, spread with astonishing rapidity, and in a few months carried off in Piedmont no less than 70,000 head of cattle. Ramazzini, Lancisi, and Lanzani, who describe this epidemic, do not hesitate in regarding it as true variola, or small-pox. Vicq d'Azyr noticed a mild form of the same malady in Picardy. What Jenner saw in 1798 was the remains of this terrible disorder.

These historical facts seem to have been unknown to the discoverer of vaccination, whose genius has shed so lasting a lustre on the title of the British physician. He evidently acted on his own sagacity, the results of which are consequently so much the more valuable, as they are the products of an enquiry the most original of its kind. But while Jenner was thus pursuing his investigations by himself, Dr. Layard, in his second paper read before the Royal Society, mentioned inoculation from cow to cow as being employed to mitigate the disease in these animals, with as much success as inoculation was practised among human beings for a similar purpose. At this period, small-pox was attracting the attention of the world. It was making great havoc everywhere; men and cattle suffered alike from its ravages; and it was remarked, that during the prevalence of the small-pox, in a given locality, several dairies would become affected with cow-pox at the same time. Horses, as well as cows, suffered from it. Jenner imputed the origin of the vaccine virus to the horse's greasy heels, which he regarded as the real source of the variolous disease in the cow. He lived to correct this erroneous notion, which, however, he had his reasons for entertaining. He remarked the disposition to grease in the horse, occurring chiefly in the spring and autumn, when the cow-pox also occurs in the dairies. He imagined that it was conveyed by the man who groomed the horse to the cow, which he likewise milked, and that in this way the cow became infected with the variolous disease. There was some truth in this supposition. For it is now ascertained that the horse, like the cow, is liable to the variolous disease, and suffers from its attacking that part of the heel, apt to become greasy, where the skin is the thinnest and most favourable to the formation of the vesicles. Hence the pardonable mistake into which Jenner fell. He was never quite satisfied with his own conclusions. His sagacity pointed out to him the want of identity in the two diseases, and some facts led him to suppose at last that the greasy heel might be a modified small-pox—an idea not far from the truth. It must have staggered his contemporaries to be told, that from the horse's heels the cow contracted a disease, which, when transferred to man, proved to be a protective against the small-pox; and yet such was

the fact, although not according to Jenner's interpretation of it.

But this is not all that relates to the variolous disease among cattle; for there is information of a much more recent date than this, and not less interesting in its character. The cows in Bengal suffer from a disease, the same as ours, and the natives call it by a name significant of the word variola. Mr. Mc Pherson, in India, vaccinated a child in 1832 with virus taken from an Indian cow, and the true variolous vesicle was produced. Mr. Wood, at Gwalpara, 1839, produced the same phenomena in the same way; only the symptoms were in his case both very severe and threatening. The intensity of these symptoms might have arisen from an accidental intensity of the disease in the cow; although, when first transferred to man, its effects are usually the more intense, in exact proportion as they approach nearer to their source from the cow.

The small-pox has been conveyed from man to the cow, just as it has been communicated from the cow to man; and Dr. Waterhouse, of Massachusetts, in a letter to Dr. Jenner, quoted in the *Prov. Med. and Surg. Journal* (vol. viii, p. 23), gives a case in point. This experiment is said to have succeeded in Berlin in 1801. M. Viborg, of Copenhagen, declares he has communicated the disease to dogs, apes, and swine. Dr. McMichael informed the College of Physicians, in 1828, that vaccine matter having failed in Egypt, the medical gentlemen were led to institute certain experiments, by which it was discovered, that by inoculating a cow with the small-pox from the human body, fine active vaccine virus was produced, by which children were vaccinated with complete success. Professor Sonderland, of Bremen, wrapped cows in sheets in which small-pox patients had slept, and thus succeeded in infecting those animals. Gassner had already variolated the cow in Germany, as far back as 1807. Dr. Basil Thiele, of Kasan, in South Russia, succeeded in similar experiments. He appears to have been successful in 1836, at a time when Mr. Ceely was fruitlessly engaged in endeavours to make arrangements for some experiments of his own. In 1838 Dr. Thiele was again successful. He fixed upon some milch cows, and operated upon them in the spring, maintaining the cow-house at a temperature of 66° Fahrenheit. The udder was the part he selected for inoculation, and the animals on which he succeeded were precisely such as Mr. Ceely rejected. Many punctures were rewarded with the result of only a few vesicles. It will be seen, that the chance of success is very uncertain, and that different operators, in different quarters of the globe, unanimously acknowledge the difficulties with which variolation of the cow from the human subject is surrounded. Perhaps we do not yet know the precise conditions under which it must be undertaken; nor are we yet sufficiently acquainted with the laws of animal poisons, to enter on the investigation with the facility proper for scientific research. Although more than half a century has elapsed since the time of Jenner, vaccination is but in its infancy, and calls for the combined energies of pathologists all over the world for its further elucidation and pursuit.

In this country, Mr. Ceely, of Aylesbury, has been distinguished for accomplishing this object. He produced vesicles on the cow, from which he vaccinated several hundred patients, who exhibited all the phenomena of vaccination in the most complete degree: there was no attendant eruption, nor anything else that could lead him to suspect that he had not in this manner propagated the genuine variola vaccina. This virus was tested by other practitioners, whose experience in vaccination left no room for doubting the just weight of their testimony; and these gentlemen affirmed that it produced regular vesicles, exactly like those so beautifully delineated in Jenner's first publication. Others, who saw these vesicles without being aware from whence the virus that produced them had been drawn, acknowledged their correctness. Nothing could be more conclusive than experiments such as these, which, in a practical point of view, established the identity of the two diseases. The cow had been inoculated with virus

taken from man, and the virus taken from the cow had produced the usual phenomena of vaccination. The fact was self-evident, and reasoning was at an end.

Moreover, since Mr. Ceely vaccinated the cow from man, it has been effected at Passy, near Paris; and the lymph found there among the cows, in 1836, has since then been passed through the animals again; and this is called retro-inoculation. The human lymph, when transmitted in this manner, loses some of its activity, rises later, and produces smaller vesicles; but it recovers its activity by successive inoculations on man again. This, again, is one of those delicate tests, which speaks for itself.

It would seem, then, that cow-pox and the small-pox are identical diseases, and that the vaccine disease is not the preventive of small-pox, but the small-pox itself—the substitute, rather than the antidote; so that the person who has been vaccinated, has had the small-pox in a mild form. Cattle are liable to the small-pox, which co-exists with the same disease as an epidemic among men. When severe in cattle, it produces by inoculation a similar severity in man; and, as man may have it from the cow, so the cow may have it from man. When a mild small-pox is taken from the cow, and conveyed by vaccination to the human body, it produces a mild disease, such as Jenner first described it; and proves to be, in the greater number of instances, an effectual protective against the infection of small-pox. No one of any experience can pretend to contradict this substantial statement of facts; nor dare to deny that vaccination, properly performed, is a positive safeguard against the small-pox pestilence. This datum is irrefragable, and forms a fixed point in the history of medicine, from which a new era commences.

Subsequently to Jenner, nothing new has been added to his original discoveries. What he saw, we continue to see, such as he described it. The inflamed point of the third day; the small pustule of the sixth; the areola, sometimes extensive and erysipelatous, of the eighth; the dark scab of the twelfth; and the black, dry crust, of the fourteenth, are the same now as they were then. He said the virus was most potent while it was lymphatic, that is, on the seventh day; and so it now is. He said that deep incisions in vaccinating, or inoculating, were injurious; and that puncturing or wounding the cuticle alone was the safest and most effectual mode of performing this little operation; and we find it to be so. He remarked, that cow-pox was not infectious, but only contagious, which every one is aware of. He considered that the areola or inflammation took place sooner in cases disposed to reject the specific action of the virus; and, in second vaccinations, we find the inflammation rising on the sixth day, instead of on the eighth. In his time, when persons performed vaccination with imperfect virus, it of course failed as a protective agent; and what happened then, happens now, and is one of the reasons why the public have lost their implicit confidence in its protective power. He declared, that vaccine virus loses none of its characteristic properties by passing through successive generations; and his declaration has proved itself correct; for, if it has failed in virtue or aspect, the failure is owing, not to successive transmissions, but either to the virus having been badly selected, or to the constitution from which it was taken being disordered at the time. There is a proper time, as well as a proper state of health, in the progress of the vesicle, when the lymph is ripe and active; but in default of this, it proves effete or immature. Jenner stated the time for taking the lymph to be from the fifth to the eighth day, just before the areola forms; and what he stated is true. Dr. Bryce, of Edinburgh, advised testing the efficacy of each vaccination by a second, performed a few days after the first. This is a beautiful illustration of the secondary vaccination running through its stages with accelerated speed: it is called "*Bryce's test*". The vesicle from which lymph is taken ought to be a perfectly correct one; otherwise, failure is likely to ensue in propagating virus with it. A deviation in the character of the cow-pox may be perpetuated by vaccinating from a previous vesicle. It is to be regretted, that sufficient attention

is not always paid to a contingency so important as this. The presence of eruptive diseases modifies the true character of the vesicle; and of these cutaneous affections, herpes is said to be the worst. One vesicle ought never to be touched, but left to run its course unmolested. It serves as a criterion of the validity of the vaccine virus. The presence of a cicatrix cannot be relied on as a proof of the vaccination being protective, although its absence is very nearly proof positive against it. A second vaccination will sometimes take effect, close by an old cicatrix of the most approved appearance. Idiosyncracies are beyond our calculation, and there is no end to them. Some resist vaccination or inoculation at one time, and then take it at another; others take the natural small-pox a second time; some never take it at all; some take it after inoculation; and others, again, have taken it as often as three times or more in the course of their lives. In some persons, the protective power of vaccination is lost or weakened by age; in others, it is never lost; and in very few, it is not even the slightest protection. These anomalies form no ground of argument either for or against its efficacy as a protective agent, but remain to be considered apart as individual elements, the relative values of which are unknown.

We are now prepared to consider the importance of the experiments performed by Mr. Ceely, of Aylesbury, and Mr. Badcock, of Brighton, both of whom have given their minds to this inquiry. It does not appear that any others have done the same as they have, in this country.

Variola was long known in the Vale of Aylesbury, as a disease infesting the cows in the autumn, winter, and spring of the year. Sometimes it would be generally prevalent, but at other times there were only solitary cases. Forty years would elapse without its making its appearance in a particular dairy; while, in a neighbouring farm, it would break out as often as twice in the space of five years. A fresh cow might bring it, or it showed itself no one knew how. Milch cows alone were not the subjects of it, neither were the uplands or lowlands its favourite haunts. It was milder in some seasons than in others, and more severe in one animal than in another. The teats of a healthy cow would become tender and hot, and the milk would diminish. Vesicles formed on the udder, around the base of the nipple: their numbers would vary, but pendulous udders had the most. The dark-red and spotted cows suffered more than those of a lighter colour. The attack lasted four or five weeks. Some of the animals escaped the disease, though it was highly contagious. The vesicles rose up in size from that of a pea to a horse-bean. They were broken in milking, which left an irritable ulcer. Each vesicle had a central depression, with a hard margin, and, if it were opened or torn, a thin amber-coloured fluid oozed out. Then a dark brown oval crust formed. On the eighth day, an areola of inflammation appeared, chiefly discernible in the light cows. Lymph burst from under the crust on the eleventh day, and on the fourteenth there was a decidedly black scab. The peculiar odour of small-pox attended the last stages of the eruption. The black crusts hung about till the third or fourth week. Twenty-one days completed the disease; the last, or crusted stage, being the most protracted.

In cows, the malady is modified by circumstances not incidental to man. The rough handling of the milkers breaks the vesicles, and disturbs the natural order of the disease; while, by milking one cow after another, they go on vaccinating and re-vaccinating the whole stock, until the several phenomena, usually so distinct when left to themselves, are all mingled in one. Thus, the primary and secondary vaccination—Jenner's vesicle and Bryce's test—are coupled in the same animal; broken vesicles are blended with whole ones; the first stage is conjoined with the last; old crusts and fresh lymph are huddled together on a single udder. Besides, the cows are liable to spurious pocks, which are not a little puzzling; for the cow-pox is not so frequent an occurrence in the dairy as to render it an easy thing to be decided on at a glance, without running the risk of mistaking a

spurious eruption for the genuine disease. And, indeed, milkers catching the false pocks, fancy themselves vaccinated, and only discover their error by being unexpectedly seized with the small-pox, from which they had imagined themselves exempt.

Mr. Ceely considers mere contact sufficient for vaccination, without any visible abrasion of the skin. The milkers contract the disease simply from handling the teats while milking, and suffer from it on their hands and face: the men, between their fingers, on the back and palms of their hands, on their eyelids, cheeks, and foreheads; the women, wearing short sleeves, on their forearms and wrists, from contact with their own hands, or the animal's body. Abscesses and sinuses sometimes follow these eruptions, as well as axillary swellings. Occasionally, those who have already been vaccinated, re-vaccinate themselves from the cow; and the symptoms of the latter are sometimes more distressing than those which they remember of their former vaccination.

There is some difficulty in procuring the primary lymph, owing to the difficulty of finding a cow properly infected with a vaccine vesicle just ripe for transfer; for the vesicle must not have been broken, nor must the matter it contains be taken away earlier than the fifth, nor later than the ninth day. And when the primary lymph has been at length procured from the cow, it is not always quite so easy to vaccinate human beings with it; because it happens that morbid poisons do not easily pass from animals of one class to those of another, as from the cow to man, and the converse. Man, indeed, more readily receives the morbid poisons of the lower animals, than they do of him; but even this reciprocal susceptibility varies so much, and is open to so many exceptions, that nothing certain can be said about it.

Mr. Ceely owns (*Prov. Med. and Surg. Journ.* vol. viii, 1840, p. 343,) that one half of his attempts to vaccinate with primary lymph failed, although vaccination from the human subject succeeded in the same persons; or else, that, if he did succeed, his success did not prevent secondary vaccination from taking effect. A small number vaccinated with primary lymph, presented vesicles of the highest degree of beauty and correctness, after more or less delay; but even then not every one of the punctures took effect. Similar results ensued with lymph taken from the hands of the milkers, or from early removes of the primary lymph. The symptoms of primary vaccination direct from the cow, are more intense and protracted than in that from man to man. Some patients need preparation before being vaccinated with primary lymph, as they used to be for inoculation for small-pox. Vaccine lymph becomes milder by transmission from man to man: more *humanized*, though its generic character and properties remain the same. Constitutional disturbance is not necessary for the efficacy of the vaccine virus, for the finest vesicles arise with the smallest amount of disturbance to the general health.

Unlike man, the cow may be vaccinated (not *inoculated*, but *vaccinated*) without abrasion of the skin; contact alone being all that is requisite for effecting it.

It is a most singular property of the vaccine virus, that, by having passed through the economy of a lower animal, it comes out with nothing more of the small-pox pestilence in it than exactly so much as is innocuous as a morbid, and yet thoroughly efficient as a protective agent. This transmutation of an infectious into a contagious disease, is as remarkable as it is inexplicable, and stimulates our curiosity to the last degree of earnest inquiry and research.

There is a good deal of expense attendant on inoculating cows with the small-pox, as well as a great deal of difficulty and uncertainty in obtaining the required results. Obstacles such as these deter others from entering on experiments likely to clear up points that still are doubtful; but they enhance the value of the data already given, and reflect the greater credit on those who have alone stepped forward to explore the question.

Mr. Badcock, of Brighton, has gone over the same ground as Mr. Ceely. In his opinion, the cows used to suffer from

the small-pox much more frequently years ago than they do now, since vaccination has become general, and helped in diminishing the disease. His attention was first drawn to this subject by the frequent occurrence of small-pox after vaccination. He himself was attacked by it; and it was this misfortune which led him to doubt the efficacy of the vaccine lymph then in vogue. He looked out for cow-pox among the cows, but found the malady, such as Jenner described it, scarcely known in the dairies. He then inoculated a cow with the small-pox virus, in 1840. A pamphlet, published in 1807, by Mr. Pruen, entitled *A Comparative Sketch of the Variolous and Vaccine Virus*, first awakened his mind to this idea. He invited several medical men to inspect the vesicle which he had thus produced, on the animal, and they agreed as to its genuine character. By means of matter taken from this cow, he vaccinated one of his own children, and produced the true vaccine vesicle. His expectations were answered. Other children were next vaccinated with the matter taken from his own child, as well as with that from the cow; and the results were equally favourable. More than twenty medical men inspected his child's arm during the progress of the vaccine vesicle, and many of them requested supplies of lymph from it, in order to ascertain its effects on others under their care. It did not disappoint any one of them. It was beyond question, that Mr. Badcock had succeeded in engendering and propagating a fresh supply of primary vaccine virus.

Soon afterwards, Mr. Ceely's similar experiments became known to him, which encouraged him to persevere in his pursuit. Residing in a populous town, where the small-pox is not unfrequent, and possessing cows of his own, which he appropriated to this particular purpose, he was enabled to inoculate some of these animals; and, out of three hundred attempts, at different times, on two hundred cows, he succeeded in infecting about thirty of them with the small-pox virus. The result of the operation is very uncertain. The most susceptible are those with calf. He never succeeded on a barren cow: he was once successful on a cow-calf, three weeks old.

Mr. Badcock has vaccinated upwards of twelve thousand children himself, with matter drawn from this source. The medical men of Brighton have frequently used the same matter, as is very well known. During one month, Mr. Badcock furnished above eight hundred charges in this town alone, besides more which he distributed to the medical practitioners resident elsewhere. It does not appear that any of the medical men have ever doubted the genuineness and efficacy of the lymph thus obtained. Children, after being vaccinated with it, have slept in the same bed with those sick of the small-pox, without catching the disease. Mr. Ceely, of Aylesbury, submitted it to the very trying test of subsequent inoculation with the small-pox, but without effect. The parish surgeon of Brighton has continued his vaccination from a stock of lymph originally drawn from one of Mr. Badcock's cows a long time since, nor would he willingly give it up. From those competent to form a just estimate of its value, it would appear that there is good ground for believing this new vaccine, or modified small-pox, to be superior to the old in the intensity of its action as well as in its certainty as a protective agent.

Mr. Badcock, who has watched its progress and effects with the closest attention, is convinced of its superiority. As far as his observation has extended, he has not known of a single failure. But then he is a clever vaccinator, and never neglects any one of those rules so indispensable to success, and to the omission of which may be imputed most of the miscarriages alleged against vaccination. When revaccination is practised, the primary lymph, such as Mr. Badcock's, is of the utmost value, on account of the intensity with which it acts, and the certainty of its taking effect, supposing the constitution unprotected by previous vaccination.

Against vaccination with primary lymph, it has been charged that it causes extensive inflammation, sloughs, etc.: and cases are quoted in illustration. But the

same objections may be urged against vaccination with Jenner's lymph, and even against inoculation with the small-pox virus. The same matter which vaccinates one child in the best and safest manner, will, in the same family, give rise in another child to disagreeable, if not alarming symptoms. But these cases are rare, and may be regarded as exceptions depending on peculiarities of health, over which we have no control. The scrofulous habit is most obnoxious to penalties of this sort: and the presence of eruptive diseases, or of general ill-health, for the time being, contraindicate the propriety of vaccination, as all the world is aware of. No one ever maintains that the introduction of vaccine virus into the system is something to be desired; on the contrary, it is, at the best, but a matter of choice between two evils—the lesser one, or cow-pox, which is harmless, and the greater, or small-pox, which is always hideous, and sometimes fatal.

The old lymph of Jenner's is supposed to have become less potent, from the length of time it has been in use, and therefore the less to be relied on. A new lymph, producing the genuine vaccine vesicle, has been obtained from the cow afresh, by previously inoculating the animal with human small-pox; and this new lymph, thus procured, is believed to be more efficacious than that of Jenner's original stock. The question is not easily settled; but the amount of combined evidence and experience speak loudly, as far as they go, in favour of the new lymph thus recently obtained.

Mr. Badcock's experiments, next to those of Mr. Ceely's, are of the highest practical importance. In this country they stand alone. Not many are likely to start up as rivals in the same pursuit; for the task involves more trouble, time, expense, and disappointment, than most people are willing or able to incur. Remuneration there can be none. The love of science alone can be the motive: and yet it is evident that, in the execution of a work, costing the continual outlay of capital, something more substantial than the best individual zeal is clearly requisite. What yields a common advantage might be maintained at a common expense. It is an undertaking that merits the general attention of the nation, and is not only not beneath the serious consideration of the legislature, but is one of those chief items of sanitary reform that concern the millions of this vast empire.

Whatever may be the cause assigned, the decline of the old lymph is acknowledged. It has been pointed out by competent observers in every quarter of the globe. In a letter to Dr. Golding Bird, in the month of December 1851, Mr. Ceely remarks: "that vaccine lymph can be and has been deteriorated by a variety of causes, is indisputable. The fact is notorious in India (*Quarterly Journal of the Calcutta Medical and Physiological Society*, April 19th, 1837); it has been proved in Paris (*Notice sur le Cow-pox découvert à Passy*, par M. Bousquet, 1836); it has been demonstrated in London (*Report on Small-pox*, by (the late) Dr. Gregory, *Med. Gaz.* Feb. 24th, 1850). That it may be rendered weak and inefficient by accident or carelessness, by ignorance, or something worse, every experienced vaccinator will readily allow." The inefficiency of vaccine has manifested itself in America. Application was made to Mr. Badcock for a fresh supply, and his new lymph was introduced into the United States by Dr. Coale, of Boston, where it was so much approved of by Dr. Clarke and the other medical officers of the Massachusetts General Hospital, that it has entirely superseded the old lymph previously employed at that institution.

In the foregoing remarks, my object has been to bring the subject of vaccination before the notice of the medical profession. My materials have been drawn from various sources; and, though I have not quoted my authorities, yet, as I disclaim anything like originality on my part, every one will feel himself entitled to appropriate what is properly his own. I have neither the intention nor wish to be anything else than a copyist. The subject is deeply interesting one, and is becoming more and more so.

so every day. It is already attracting the attention of the legislature. In the army, it is an indispensable requisite; in private practice, it is of paramount importance, because the validity of vaccination depends on the skill and care of the vaccinator.

Brighton, March 16th, 1853.

SKETCH OF THE CHOLERA EPIDEMIC WHICH PREVAILED AT SOUTHAMPTON IN THE SUMMER OF 1849.

By W. S. OKE, M.D., Senior Physician of the Royal South Hants Infirmary.

(Read before the Southampton Medical Society, Feb. 1st, 1853.)

BEFORE entering upon the more immediate subject of this paper, I deem it right to make a few introductory remarks upon the town in which we live.

TOPOGRAPHY. Southampton is situated in 50 deg. 54 min. 34 sec. N. lat., and 37 min. 7 sec. W. long. It occupies a tongue of land, about a mile in breadth, abutting towards the S.W., upon a small inlet of the sea, called the Southampton Water, which flows and ebbs N.W. and S.E. It is bounded on the east by the Itchen river; on the west, by a bay of the inlet; and on the north, by a wooded common, gradually rising to an elevation of 234 feet. It is, for the most part, built upon a bed of gravel, beneath which is argillaceous deposit. The sea in its ebb, especially at spring tides, recedes to a considerable distance, exposing an extensive surface of muddy sand, the appearance of which has been considered by some metropolitan physicians to be a *prima facie* evidence against the salubrity of the town; but this charge is completely disproved by the fact, that the exhalations at low water by the solar rays have never been productive of any endemic febrile disease whatever, whether intermittent, remittent, or continued. Indeed, the flow of the tides, and the ventilation almost always accompanying it, will probably ever prevent such a result; in confirmation of which, there are not many towns in the United Kingdom, with an equal amount of population, where so few cases of such fevers are registered. It is true, that the registrar's books show a high rate of mortality in its crowded districts, especially in the parish of St. Mary; but it is clear that this has not been caused by malarious exhalation at ebb-tides, for the same registry shows that, in the less crowded districts, parts of which are also contiguous to the water, the rate of mortality is not higher than that of some of the most healthy towns in Great Britain. The cause, therefore, must be sought for elsewhere; and doubtless it may be found in the rapid increase of population which of late years has taken place, from the extensive establishments connected with railways, docks, and steam-navigation companies.

POPULATION.

Increase in decennial periods.

In 1801, the population was 7,629	
1811, 9,260	1631
1821, 12,913	3653
1831, 18,670	5757
1841, 27,103	8433
1851, 34,092	6989

It will thus be seen that, in a cycle of twenty years, the population of the town has been nearly doubled; and, taking the parish of St. Mary alone, the increase is still more remarkable; the amount in 1831 being 8,530, and 21,012 in 1851! These statistics of the population have been introduced to account also for the great difference betwixt the two choleric epidemics which invaded Southampton, as regards both their extent and mortality.

ORIGIN AND PROGRESS OF CHOLERA. The pestilential cholera of the nineteenth century* commenced at Jessore,

* That the very same disease was known as early as the first century, the following quotation from Celsus will clearly show:—"Primoque facienda mentio est cholerae; quia commune id stomachi atque intestinorum vitium videtur. Nam simul et dejectio et vomitus est: preterque hæc inflatio est, intestina torquentur, bilis supra infraque erumpit, primum aquæ similis, deinde ut in eâ recens caro lota esse videatur, interdum alba, nonnunquam

a populous town in the Delta of the Ganges, in 1818, from which point it spread in every direction throughout India and Asia, confining itself to that quarter of the globe till 1831, when it took a north-western course through Russia, Poland, Austria, and Prussia; ravaging Vienna, Berlin, and Hamburg, in its way to Great Britain, where it made its first appearance at Sunderland on the 26th of October, 1831; but no cases were reported in London till the middle of February 1832.* The disease first invaded Southampton in the summer of 1833. As it was ushered in by a case which terminated fatally in a few hours, a great panic was caused, especially as cholera prevailed in many parts of the kingdom. The patient was a poor girl of the age of puberty, residing in Russell Street, St. Mary's. Her friends attributed the attack to a meal of cockles, which might indeed have been an exciting cause; but the symptoms were too characteristic to be mistaken. Every attention was paid which the urgency of the case required; and her medical attendant remained at her bed-side till she sank from exhaustion under incessant vomiting and purging of rice-water evacuations. The bedding, bed-clothes, and everything that could be the means of propagating the disease, were burnt by the order of the municipal authorities: and the house was cleansed and whitewashed. Whether from these precautions or not, the disease did not spread; nor did it prevail to any extent in other parts of the town; so that the number of cases were not probably more than twelve, nor the deaths above four. The population at this period may be estimated at about 20,360. From this time the town was free from cholera till the year 1849, when it was again visited by the disease, and far more severely than before. The second epidemic commenced on the 17th of June, and terminated on the 21st of September, at which period the population had increased 25·78 per cent., and amounted to about 30,000.

METEOROLOGICAL REMARKS. During the prevalence of the disease, Dr. Drew's Meteorological Register gives the following results; and the public are much indebted to this gentleman for establishing and superintending a register at Southampton, which, for its accuracy and completeness, is probably equal to any in the kingdom.

Barometer.

	Date.	Highest.	Date.	Lowest.	Mean.	Monthly Range.
June	3rd	30·215	10th	29·633	29·988	·582
July	12th	30·344	24th	29·479	29·934	·865
August	20th	30·366	13th	29·629	29·997	·737
Sept.	19th	30·319	30th	29·198	29·886	1·121

Thermometer.

	Date.	Highest.	Date.	Lowest.	Adopted Mean.	Monthly Range.
June	24th	87·0	11th	42·5	60·1	45·1
July	16th	83·	1st	42·6	60·3	40·4
August	8th	77·6	17th	41·6	60·7	36·
Sept.	5th	76·6	19th	37·6	56·6	39·

N.B. On the 11th of July, the thermometer in the sun, at 2 P.M., was 120; in August, 104.

Hygrometer.

	Degree of Humidity.	Inches of Rain.
June	·731	0·992
July	·775	5·128
August	·820	0·451
Sept.	·852	4·531

Sept.	·2	1st. Thunder and lightning for 2 hours

The principal points to be noticed in the foregoing results are, 1st, that the temperature of the atmosphere was

nigra vel varia. Ergo eo nomine morbum hunc *cholera* Græci nominant. Sepe etiam crura manusque contrahunt, urget sitis, anima deficit: quibus concurrentibus, non mirum est si subito quis moriatur. Si post suppressam cholerae febriam manet, alvum duci necessarium est: tum cibis vinoque utendum est."—Liber iv, ch. xi.

* Copland's Dictionary.

comparatively high; 2nd, that, as the epidemic declined, the thermometer fell in fourteen days from 76°6 to 37°6; and thirdly, that, from June to the end of September, the weather was remarkably still, not amounting to 1 of the above scale: but whether these facts had any influence over the epidemic, one way or another, it is difficult to determine.

MORTALITY. The registered number of deaths from this epidemic was 239; but to state with accuracy in what proportion the deaths were to the number of cases treated, is scarcely possible. I have, however, obtained from a gentleman who attended the largest amount of parochial patients, some statistical facts, which will enable me in some degree to make the attempt. He states that, including incipient or diarrhoeal cases, he noted down 1,500 as having been attended by himself, and that of these, 40 died, or 1 in 37: 37×239 will give 8,843, which is probably about the number of cases, of all grades, that were under treatment by the medical gentlemen of Southampton. His note-book furnishes also the following particulars: that the epidemic was most malignant from the 14th of July to the 14th of August, and that, during that period, he attended 360 cases, of which he considers the cases of diarrhoea and true cholera were about equally divided; that of the latter, viz., 180, 90 ran into collapse; that of these, 40 died, or 1 in 2·25; that of the whole of the cases of true cholera, the deaths were one in 4·5, and of all attacked, 1 in 9: but, in the approach and decline of the disease, the deaths were not more than 1 in 37.

It is important to remark that, whilst the disease fearfully prevailed amongst the inhabitants in crowded and ill-drained districts, it attacked but few of those who inhabited the less crowded localities. This fact greatly strengthens the opinion, that the extent and mortality of this epidemic was not the result of malaria from the bed of the river, but of an over-crowded state of the dwellings of the working classes; otherwise, the first epidemic must have been, in proportion to the population, as severe as the last.

DESCRIPTION OF THE DISEASE. The epidemic of 1849 began at a beer-shop in the middle and south side of Bridge Street, which was at that time a close, narrow, and ill-drained thoroughfare. The patient was a married female, of stout make, about forty years of age, and the mistress of the house. The attack was most severe and alarming, and came on after a supper from mackerel. She was promptly visited by her medical attendant, and, by his unremitting efforts, the judicious use of the hot-air bath, and decided doses of calomel and morphia, she was brought out of collapse, and the severity of the symptoms controlled. I was requested to see her early in the attack; and, as the house was extremely close and crowded, we advised her removal to an airy situation a short distance from the town, which was accomplished without delay. Fever of a low character followed the suppression of the cholera, which was complicated with gangrenous erysipelas of the inferior part of the abdomen, and upper and internal surface of both thighs, from which also she eventually recovered, although the suicide of her husband, in the midst of her illness, rendered her case still more critical.

Cholera was not communicated to any one who waited upon or nursed her at either house; but at the same time it broke out in many other parts of the town, till the disease, associated with diarrhoea, became very general.

At a meeting of the medical men, it was found convenient to divide the symptoms into four stages—the premonitory diarrhoea, the serous flux, the partial collapse, and the complete collapse.

1. *Premonitory Diarrhoea.* This was characterized by head-ache, loss of appetite, nausea, and oftentimes vomiting, relaxed bowels, with or without pain, and a discharge of a thin faecal matter, generally of a pale colour, occasionally mingled with bloody shreds, and remarkably fetid. This stage lasted for some days, or only a few hours.

2. *Serous Flux.* In this stage there was increased vomiting and purging; pumping out profuse liquid evacua-

tions, sometimes like dirty barley-water, but more commonly resembling water having a ground-rice sediment. These were without faecal smell. There was then also a diminished or suspended secretion of urine, intense thirst, especially for cold drinks, agonizing cramps, a failing pulse, and an anxious aspect. This condition, unless timely checked, did not last long before it ran into partial collapse.

3. *Partial Collapse.* This period of the disease was marked by a dark colour of the skin, but more commonly by a leaden or bluish tint, senile expression of the countenance; sinking of the eye-balls into the bottom of the orbits; atrophied and shrunken state of the body, especially of the fingers; imbecility of the voice; pulse at the wrist scarcely perceptible; diminished temperature; clammy sweats; laboured breathing; and constant changing of position from one side to the other.

4. *Complete Collapse.* There were withered aspect; eyes dim and half closed; the surface of the body, particularly of the face and extremities, as cold as marble, and covered with a damp sweat; no pulse at the wrist; gasping respiration, and a moribund condition; but the intellect was generally clear to the last.

It is not intended to be understood that the disease was generally found to observe such deliberate and distinct grades. In many cases the patient was at once brought into the second stage; and in some, whilst engaged in his ordinary concerns or employment, with scarce any warning he became pulseless, cold, and shrank into a fatal collapse.

The secondary fever of cholera was not constantly observed in this epidemic. Those who were exempt from it became speedily convalescent. In those affected by it, the febrile symptoms were of an asthenic character, requiring support and great attention to conduct them safely through the sequelæ.

CAUSES. The pathology of cholera, and, indeed, of pestilential diseases generally, is but imperfectly understood. They all appear to select different organs of the body for their respective development. Thus small-pox selects principally the external and internal surfaces; plague and yellow fever, the brain; influenza, the respiratory passages; cholera, the stomach and small intestines; and dysentery, the large intestines; and all, by such selection, assume distinctive characters.

Sporadic cholera is doubtless sometimes produced by accidental causes, such as unwholesome and poisonous food, etc.; but it is supposed that *pestilential cholera* is derived from some abnormal condition* of the atmosphere, and that a specific poison from this source enters the body through the air-cells of the lungs, where it corrupts or destroys the vitality of the blood, embarrasses the respiration, weakens the force of the heart's action, and rapidly diminishes the animal heat, at the same time relaxing the oscula of the mesenteric veins, and permitting the escape of the serum of the blood into the intestinal canal, and throwing into vehement spasm, and utter disorder, the ganglionic centres. This description, however, is merely theoretical, drawn from the evidence of symptoms, not based upon appearances observable after death; indeed, the facts presented by morbid anatomy go but little way in explaining the pathology of cholera. If death take place very early in the attack, scarcely any change is observable in the internal organs except as to their colour; and if later, the principal changes which present themselves are, a tar-like consistence of the blood; the surface of some portions of the mucous membranes, especially that of the small intestines, coated with a whitish, opaque, viscid substance, of a muco-albuminous character; and the mucous membrane of this part of the intestinal canal occasionally assuming an unnatural whiteness, and so soft and pulpy, as to be easily detached from the subjacent coat. The abdominal viscera are also congested with dark-coloured blood, which is sometimes also

* Sydenham has handed down to us the "epidemic constitution" of certain consecutive years, to show the diseases which prevailed during each period; and if such observations were made at the present time, with the instruments we possess, our knowledge of pathology in pestilential diseases would be greatly increased.

found in the left side of the heart. From these appearances, Dr. Turnbull Christie,† who has written a valuable treatise on this subject, was led to believe that cholera is a disease of the mucous membranes, and, in fact, a catarrh of the intestines; but as neither the symptoms nor the morbid appearances after death are at all analogous with catarrhal affections of other mucous membranes, such an opinion is not tenable. Both are doubtless the peculiar effects of a morbid aerial poison; but what are its essential elements, and from what pestiferous source it is primarily derived, will probably be long withheld from the grasp of human intellect.

CONTAGION. Much has been adduced as to cholera being a contagious disease, on both sides of the question, without arriving at any settled conclusion. This difference of opinion in medical men of equal talent and observation is somewhat remarkable; and yet, I think, it admits of an easy explanation, by assuming two examples. In the first, a physician is called to a member of a family, resident in a locality where the atmosphere is impregnated with choleric poison. His symptoms are those of cholera. In a few days a brother, whilst attending his relative, is attacked; and shortly afterwards, several other members of the family. A neighbour, also, who had called to inquire, becomes affected in the same way. Such a series of attacks would reasonably induce almost any medical attendant to infer that the disease was communicated from person to person, and to pronounce it fearfully contagious.

In the second example, another physician, practising in the same district, is called to attend several cases of cholera in the same day, which could have had no communication whatever with each other; he, therefore, sees the propagation of the disease in quite a different light, and pronounces it at once to be epidemic, and not contagious at all. It must be allowed that both opinions are based upon very strong, if not equal, grounds; and hence it is that the disputants defend their respective positions with so much obstinacy. There can be no doubt that contagionists may, in most epidemics, adduce proof of the morbid elements of cholera having been propagated from one patient to another, either by the vapour of dirty linen in the act of being washed, or by human exhalation in crowded, ill-ventilated apartments; for surely there is nothing unreasonable in asserting that cholera, like many other epidemics, may, under circumstances favourable to such a result, reproduce itself. In my own opinion, however, it ought not to be classed with diseases avowedly contagious, because, by sanitary precautions, such a result may be, in great measure, prevented; and this opinion is supported by the fact, that the Southampton epidemic could not be traced to any contagious source whatever; that it was not communicated to any persons who attended the incipient cases; and that, of all the medical gentlemen who were engaged in the thickest part of the epidemic, both day and night, for weeks together, and whose courage, energy, and attention could not be surpassed, not one of them was disabled by the pathognomonic symptoms of the disease.

SANITARY MEASURES. As soon as it was announced that pestilential cholera had invaded the town, a conference took place between the municipal authorities and the medical practitioners, with the view of carrying out the most approved sanitary measures. Districts were formed, and visitors appointed to each; the sewerage was made as effective as possible by as good a supply of water as could be spared from the reservoirs; the markets were vigilantly inspected, and the sale of everything likely to conduce to the disease, such as overkept or bad meat, stale fish, and every kind of shell-fish and unwholesome fruit, was strictly prohibited. Lodging-houses, crowded with vagrants, were inspected; their inmates dispersed; their rooms cleansed, whitewashed, and ventilated; and their privies disinfected and deodorized with quick lime. And as many of the lower classes were constantly found in a state of intoxication by

the free use of brandy to avoid the disease, but thereby became more disposed to it, hand-bills, printed in a plain type, were circulated, assuring them that, by observing temperance, a calm demeanour, and a plain nutritive diet; by keeping their dwellings clean, and well ventilated; by protecting the body with good and sufficient flannel whilst exposed to wet and cold weather; they would, in all probability, preserve their health, and stop the spread of the disease.

MEDICAL TREATMENT. With a view to prevent an increased development of cholera, every case of diarrhoea was regarded with suspicion, as being probably the incipient stage of the epidemic, and controlled, if possible, at once; carefully avoiding saline purgatives of every kind, fruit, vegetables, and fermented drinks; and restricting the diet to plain animal food and the farinaceæ. This was best effected by the cretaceous mixture, combined with the tincture of catechu, aromatics, and laudanum. Indeed, the early treatment of diarrhoea was considered so important, that a medicine of this kind was kept prepared at the Dispensary in the High Street, ready to be given to all who were attacked with these symptoms. A medical gentleman was also in constant attendance, to advise those who applied; and public notice was given to that effect.

Treatment of the Second Stage. If the means adopted failed to control the diarrhoea and vomiting, and profuse watery purging, without faecal smell, severe cramps, and inordinate thirst, clearly indicated the pathognomonic symptoms of cholera, the greatest attention was paid to the case, and the most decided treatment adopted, from the conviction that this was the last ground afforded for combating the disease upon equal terms. The patient was put to bed between blankets, his apartment kept airy, and his strength supported by clear animal jellies, rendered still more nutritious by some of the farinaceæ, to which spice and brandy were added. One grain of the acetate or hydrochlorate of morphia, and five grains of calomel, were given immediately. In two hours afterwards, two grains of calomel, with half a grain or a grain of opium, accompanied with a fluid-ounce of the subjoined mixture, were administered at shorter or longer intervals, according to circumstances:—

Rx.—Confect. aromat. 3ij,
Ætheris chlorici,
Tincturæ capsici, aa 3ij,
Sp. ammoniæ aromati,
Syrupi aurantii, aa 3ij,
Tincturæ opii 3iss,
Spiritus menthæ piperitæ 3j,
Mist. camphoræ ad 3vj. M.

If the symptoms did not yield to these means, a suppository of three grains of opium was introduced within the rectum, and repeated in four hours, if needed. At the same time, a fold of flannel, moistened with equal parts of the oil of turpentine and camphor spirit, was applied to the whole abdomen, and confined there by a flannel bandage.

This treatment appeared to be most entitled to confidence in this stage of the disease; but, as it often happened that one symptom more than others distressed the patient, and demanded especial attention, it was met by such means as were deemed most suitable to subdue it. If the serous flux continued to exhaust the strength, it was treated with three or four grains of the acetate of lead, and one of opium, every hour, or at even shorter intervals, if the urgency of the case required it. If the vomiting predominated, a large blister was applied to the epigastrium, and two drops of the dilute hydrocyanic acid were given in a drachm of water, after every copious vomiting. If severe cramps harassed and agonised the patient, the following pills were given every half hour:

Rx. Pulv. opii gr. ij,
Camphoræ gr. vj,
Mist. acaciæ q. s.

M. et divide in pilulas duas.

In the event of their failing to subdue the cramps, the inhalation of chloroform was used with the happiest effect, and re-

† Observations on the Nature and Treatment of Cholera, and of the Pathology of the Mucous Membranes. By Alex. Turnbull Christie, M.D.

peated again and again, if the return of the cramp required it.

Treatment of the third stage. In advanced stages of cholera, when life was fast ebbing under the force of the disease, the success of any mode of treatment was at best but very uncertain. Nevertheless, such cases were not despaired of: on the contrary, as a considerable number had recovered from a partial state of collapse, every possible resource and redoubled energies were called into operation. The temperature of the body was raised by the hot-air bath, if at hand; if not, by warm blankets, bottles of hot water, terebinthinate epithems, mustard poultices, and other convenient appliances; and the system was supported by stimulants and strong animal jellies. The method of medical treatment adopted in this stage by different practitioners were, one or two grains of calomel every ten minutes or quarter of an hour, which is a modification of Dr. Ayre's treatment; large doses of opium and camphor according to Dr. Hawthorn's plan; bleeding, after having raised the pulse by essential aromatics and æthereal stimulants; and cold water *ad libitum*.

Of these several methods of treatment, the calomel, where the strength could bear it, was found to be comparatively the most successful; but its therapeutic effects were limited for the most part to young persons. Beyond the adult age it generally failed. I saw it fairly tried in some cases of the latter, in which it had no power whatever to arrest the fatal progress of the disease. One medical gentleman was bold enough to adopt Hawthorn's huge doses of opium combined with camphor; and in two cases it was reported to have rescued the patients from a desperate state of collapse: but the practice was not continued, probably, from the dread of inducing a fatal narcotism; indeed, it is to be feared that in some instances such a result actually took place from the heroic doses of morphia and opium which were administered, and which the menacing character of the symptoms appeared fully to justify. The abstraction of blood from a patient in this stage of cholera seems to be wholly irreconcilable with the symptoms; yet I was informed by a gentleman actively employed in the epidemic, and assisted by an army-surgeon who had often attended cholera in India, that he saw several cases of collapse cured by this treatment. The only way of explaining the success of this desperate remedy is by the possibility of its relieving the venous congestions which are found to exist in this disease, and thereby allowing the arterial blood to pass through the capillary system with its vitalizing resources. With regard to cold water drank *ad libitum* in collapse, another gentleman, who was also in the midst of the pestilence, reported that, having several children under his care in this state, and having totally failed to benefit them by every other means in his power, he allowed them to slake their craving thirst for cold water with unlimited quantities, and that by this treatment alone they recovered.* The good effect of this remedy would mainly depend on the water being imbibed by the oscula of the mesenteric veins opening upon the villous coat of the intestinal canal. If it merely passed through the canal, the diarrhoea would probably be increased and a fatal issue accelerated: but, if imbibition took place, the water might become a floating medium and an oxygenating pabulum for the blood-corpuscles, and thus increase their vitality.

The saline treatment was but seldom adopted. I advised a trial of it, according to Stevens's plan, in the case of a gentleman, aged 55, the progress of which was not rapid, and where it appeared to be well suited to control an incessant vomiting that greatly distressed him. This symptom it certainly did relieve, and also improved the colour of the stools: but, on the other hand, it aggravated the diarrhoea, which brought on a fatal collapse.

Treatment of the fourth stage. It would be in vain for me to recommend any mode of treatment for this stage of the disease, as there was none that deserved the slightest confi-

dence: all alike failed. There were, doubtless, a few cases that recovered even from this extremity; but these were bare exceptions to the general rule of death. In some, the complete collapse was gradually brought on by a persistent diarrhoea as in the instance last mentioned; whilst in others the patient was at once blighted and killed by the intense power of the choleric poison. The following is an example of the latter.

A young man, in the prime of life, and in good health, during the height of the epidemic, brought into Southampton a load of grass from the borders of the New Forest. Soon after he had delivered his commodity in East Street he was attacked with cholera, and returned towards home: but he had not passed through Mill brook—a distance only of two miles—before he was found in a state of complete collapse. He was taken into a public house and immediately received the utmost attention from two medical gentlemen, who placed him under Ayre's treatment. Happening to be passing by, I was requested to visit him. His intellect was clear. The skin was of a darkish brown colour; his extremities cold; his pulse scarcely perceptible; he was shrunk up, and constantly changing his position from one side to the other. Everything failed to bring on reaction, and he sank in a very few hours. In this character, cholera may be emphatically termed "the pestilence that walketh in darkness and destroyeth at noon-day". Beneath its malignant power the physical strength of man is mysteriously brought to nought, and "fades away suddenly like the grass". "In the morning it is green, and groweth up: in the evening it is cut down, dried up and withered."

Southampton, February, 1853.

TREATMENT OF SIMPLE ERYSIPELAS AS A LOCAL ACUTE DISEASE.

By JOHN HIGGINBOTTOM, Esq., F.R.S.

(Read before the Midland Counties' Branch of the Provincial Medical and Surgical Association, at Nottingham, March 10th, 1853.)

I WISH to bring before my professional brethren the following questions.

1. Is simple acute Erysipelas a purely local, or a constitutional disease?
2. Is it sometimes a local, and sometimes a constitutional disease? or,
3. Is it simultaneously both, a local and a constitutional disease?

I am of opinion that it is in all cases purely local; and that the constitutional symptoms are a result of the local disturbance. This opinion I have formed from the following facts.

1. I have had a number of cases of erysipelas on the face and elsewhere, where there have been no constitutional symptoms; in these the disease has been directly arrested and subdued by the application of the nitrate of silver. Now, it is my opinion that, if the erysipelas had been allowed to proceed without the local application, severe constitutional disturbance would have been the result.

2. If from exposure to wet or cold, etc., a feverish attack should come on, and in several days erysipelatous inflammation should supervene; on a prompt application of the nitrate of silver, along with the use of common remedies for the cold, the patient becomes convalescent in a few days: but if the local application is neglected, the inflammation runs its usual course, the constitutional symptoms become more aggravated, and the illness is much prolonged.

3. If the erysipelas and constitutional symptoms are simultaneous, a prompt application of the nitrate of silver, and the use of active constitutional remedies, cut short the disease; and the patient is convalescent in a few days. But if the local application is neglected, the disease runs its usual and often destructive course, setting at naught the most active constitutional treatment.

* Vide Notes on Cholera, by Dr. Gilchrist, Inspector-General of Army Hospitals, etc.

In my *Further Observations on the Nitrate of Silver*, p. 31, is related the following case, which will illustrate what I have advanced.

CASE I. (Mrs. S., some years since, had a severe attack of erysipelas of the face and head, which ran its course under the old medical treatment; the effects of the disease were so severe as to confine her to her bed-room for six weeks.

In November 1845, she had another attack of erysipelas, which had progressed twenty-four hours before I saw her. A decided application of the nitrate of silver was made to the parts affected, and purgatives were given. She was convalescent in seven days.

The following year, in October, erysipelas again made its appearance on the face. She had taken a purgative before I saw her. One decided application of the nitrate of silver was sufficient, and she was not confined to her house a single day. No further remedies were required.

Mr. Nunneley, of Leeds, in his monograph on Erysipelas, says (contrary to his own opinion), that Dr. Smyth, Mr. Earl, Mr. Arnott, Mr. James, and Mr. Lawrence, consider that "erysipelas is essentially a *specific disease*, affecting one tissue alone, characterized by the local disorder, which forms the chief symptom and upon which the constitutional disturbance depends."

From the commencement of my treatment of erysipelas with the nitrate of silver, I have considered it a local specific disease; and this view appears to be supported by the speedy subsidence of the fever, as soon as the local disease has been subdued by the application of the nitrate of silver.

Erysipelas may be considered as the result of a poison, *sui generis*. It remains at first like a small patch on one side of the nose, cheek, or elsewhere, and makes often no progress for twelve or twenty-four hours, continuing so long as to generate its own poison, which is then carried into the system; and at this period, the constitutional symptoms commence.

The following are my reasons for believing that erysipelas is a local disease; which I wish to repeat.

1. If erysipelas makes its appearance on the face without constitutional disturbance, the prompt application of the nitrate of silver alone is sufficient to arrest and subdue the disease.

2. If fever and constitutional symptoms come on before the appearance of erysipelas, the simultaneous use of the nitrate of silver and constitutional remedies cut short the disease, and the patient is convalescent in three or four days. But, if constitutional remedies alone are used, and the nitrate of silver neglected, the disease will commonly run its usual course.

3. If the erysipelas and constitutional disturbance come on simultaneously, the prompt use of both the nitrate of silver and the constitutional remedies arrest and subdue the disease. If the nitrate of silver is omitted, the disease runs its usual course.

4. Whether the disease be idiopathic or traumatic, the erysipelas has the same characteristics. The inflammation spreads and produces the same dire effects; first, on the skin; second, on the cellular tissue; third, on the mucous and serous membranes. Both the idiopathic and the traumatic erysipelas are cured by the same means.

Of course, the disease is often mild or aggravated, according to the healthy or unhealthy state of the patient, whether temperate or intemperate. I have always found consumers of alcoholic drinks most difficult to cure, in erysipelas as well as in all other diseases; and if they were banished altogether from medical practice, acute disease would be sooner cured, and chronic disease would be more manageable.

I do not believe in the occurrence of metastasis in erysipelas. That distant parts are affected in erysipelas is true: but this appears to me to be caused by the extension of the disease, and by the specific poison of the erysipelas carried into the system.

I would make an observation here which I have often insisted upon; viz., that in all cases a strong solution of

nitrate of silver should be used—one scruple of the nitrate to one drachm of distilled water. I not only use this strong solution, but also rub the stick of the nitrate of silver on any particular part where I wish it to be well applied. I have attributed the failure of this excellent remedy in the hands of some surgeons to the use of a weak solution; and this I have named, with other causes of failure, in my *Additional Observations*, page 19. In an excellent paper, by Dr. W. S. Oke, published in the *ASSOCIATION MEDICAL JOURNAL* for January 21st, 1853, p. 53, "On Erysipelas, etc." he mentions a surgeon who has used the nitrate of silver successfully, with a solution of one scruple of the nitrate of silver, six drops of the nitric acid, and one ounce of water. I am sure such a weak solution cannot be depended upon. I never knew a very free application of the strong solution, or the stick of nitrate of silver, "produce the destruction of the cutis vera," or be attended with any ill consequences.

Dr. Oke says, "the Royal South Hants Infirmary, in common with other hospitals, has been occasionally invaded by erysipelas with an average result; but since the nitrate of silver has been employed, the unfavourable terminations have been comparatively very few; and, I am persuaded, that were this excellent remedy more frequently adopted, erysipelatous inflammation might be generally controlled."

From a late epidemic of erysipelas in Nottingham, I have selected six cases; four where the nitrate of silver was applied, and two where it was omitted; the results of which were in accordance with my experience for the last twenty years.

CASE II. Mr. M., a railway clerk, aged 26, had erysipelas on the left side of his face, not reaching the scalp. He was slightly indisposed. One decided application of the nitrate of silver was alone required. He took an ipecacuanha emetic, followed by a calomel pill and purgative draught, and a saline mixture. He only required visiting four days.

CASE III. Mr. F., a farmer, about 50, a free liver, called at my house to consult me, having an erysipelatous inflammation of the face upon the right ear. It was spreading near the scalp. He was so little indisposed, as to be able to ride five miles on horseback to visit me. I applied directly, and very freely, the nitrate of silver to the inflamed part close to the scalp, and on and beyond the inflamed ear, fearing much that the scalp would become affected. I thought proper to prescribe for him an emetic of ipecacuanha, a calomel and colocynth pill at bed-time, and the following morning an active purgative mixture. He returned home on horseback, and I heard nothing more of him for a week, when he sent for a repetition of the purgative mixture, with a message that the inflammation was quite gone.

CASE IV, v. In October 1852, two sisters, between 20 and 30 years of age, living together in the same house, had erysipelas. The eldest had been indisposed for several days before I saw her, and the disease was attended with much constitutional disturbance—the erysipelas having partially affected the scalp. I thought it necessary to have the whole head shaved (although it caused considerable pain), so that I might apply the solution of the nitrate of silver freely to the whole scalp. The usual constitutional remedies were used. In this case the recovery was more tardy, on account of the application of the nitrate of silver having been so long delayed. A troublesome inflammation of the eyes was produced in this case, by the neglect of applying the nitrate of silver on the inflamed eyelids, which should always be attended to, in order to prevent inflammation of the conjunctiva.

The younger sister, disliking the application of the nitrate of silver, was desirous of taking an emetic and purgatives, to check the inflammation; but finding the erysipelas to come near the scalp, she submitted to a very free application of the nitrate of silver, which extinguished the inflammation, and she was glad that her hair was preserved.

In the two following cases, the nitrate of silver was not applied.

CASE VI. Mr. G., aged 54, of a gross habit, a habitual

consumer of alcoholic drinks, and a smoker of tobacco (but not an intemperate man), had in October a catarrh, and felt generally indisposed. There was a slight blush of erysipelas on the left side of the face, but not sufficient to excite any particular attention. Remedies were employed for his catarrh, but no local application was used to the erysipelas. The inflammation progressed over the scalp, and produced cerebral disturbance, which, however, was not severe; the throat and the mucous membrane of the larynx became inflamed; the irritation and cough increased; the constitutional symptoms were now very severe; the mucous membranes generally were affected; the joints were affected with severe pain and inflammation (similar to rheumatism), and the secretions were diminished in quantity, and in a vitiated state. A general bad state of body was induced, and after suffering a number of weeks, he died.

In this case all the severe symptoms followed the increase of the erysipelatous inflammation, and I think would have been prevented by a prompt and early application of the nitrate of silver.

CASE VII. In November, Miss J., aged 35, was attacked with a slight erysipelas on the left side of the cheek and nose. No external application was used. An emetic, active purgative, saline draughts, and repeated doses of calomel and James's powder, were given. The erysipelas progressed over the scalp, down to the neck, and a little on the chest. A continued and severe indisposition was the consequence, attended with cerebral disturbance, producing delirium for several days; for which blisters were applied to the nape of the neck. Several large abscesses formed in the neck and chest; the last of which was opened in eight weeks from the commencement of the erysipelas.

The above two cases were all I had attended for some years, where the nitrate of silver was not applied. Both were mild in the commencement. The result showed the necessity of a prompt and decided application of the nitrate of silver, even in the slightest attacks of erysipelas, to prevent future evil consequences. In the last case, all the severe illness would have been prevented by a timely application of the nitrate of silver. I do not say it *might* have been prevented, for the continued experience of twenty years or more has assured me of the practical truth, that it *would* have been prevented. I have had no case where abscesses have formed, when the nitrate of silver has been early and well applied in erysipelas.

I have found that a very decided application of the nitrate of silver in PHLEGMONOUS ERYSIPELAS has the extraordinary power of preventing the destruction of the subcutaneous cellular tissue, by preserving the integrity of the cutis vera, and subduing the cuticular inflammation. Even in a patient, where the limb has been as large again as the other, in which it could be scarcely expected to be benefited, the application has so far modified the inflammation as to render it a case of simple phlegmonous abscess, which has been relieved by a free opening with the lancet, and where there has been no loss of cellular tissue.

CASE VIII. Mrs. B., aged 68, living in a low part of the town (Narrow Marsh), had phlegmonous erysipelas of the whole of the right leg, extending a little above the knee on the thigh; the leg was as large again as the natural size, and was very tense and painful; there were some vesications on the fore part of the leg; the patient had been neglected, till the state of the limb alarmed the friends. I directed an emetic, purgative, and saline mixture, and applied the strong solution of the nitrate of silver very freely on the whole of the leg, and on and above the inflamed part of the thigh. The following day, the nitrate of silver had had the desired effect of allaying all irritation and inflammation, in which state it remained for four days; on the second and third day, a considerable degree of vesication had taken place, from the free application of the nitrate of silver; but I found the limb did not at all diminish in size; on that account, I knew from former cases, that suppuration had taken place. On the sixth

day, I made a free opening about two inches in length at the most depending part, about the middle of the limb; a large quantity of pus was evacuated, but there was not the least appearance of any sloughing of the cellular substance. In a few days afterwards, I made a small opening above the outer ankle, from which some sero-purulent matter was evacuated; and in a few days, on the opposite side of the limb, from which issued only a little serous fluid. The limb quite recovered. No further application was required, beyond the black lint and nitrate of silver to the sores, and a common linseed poultice constantly applied, repeated every eight hours. I never knew a limb in the same state, under the common mode of treatment, which terminated so favourably.

Nottingham, March 10th, 1853.

ON THE IMPORTANCE OF AUSCULTATION.

By F. G. PROBART, M.D., Senior Physician to the Suffolk General Hospital.

THE epoch is not so remote but that it must be well remembered, when the stethoscope had not only to contend with a variety of prejudices against its adoption; but, in many quarters, where more liberality might have been expected, was even ridiculed and despised.

The period, however, gradually succeeded, when many of those practitioners who had been foremost in contemning this instrument, were compelled both to respect its adoption in the hands of others to thoracic diagnosis, and even themselves obliged, in order to maintain the countenance of their patients, to employ it in the investigation of disease.

At length, the stethoscope is the constant companion of almost all members, whatever their grade, of the medical profession. The majority of them are, no doubt, fully competent to its exercise; but not a few otherwise qualified practitioners, it cannot be denied, have, even now, either from an imperfect power of discrimination in sounds, a too limited practice, or reprehensible neglect, a very inferior knowledge of its diagnostic applicability—a fact that must occasionally be realized in the experience of all who have adequate opportunities for observation. Some excuse themselves for the neglect of auscultatory diagnosis, relying as they say upon the ordinary and sufficiently significant evidence, otherwise presented by the respective diseases of the thoracic viscera. But, as examples of the fallaciousness and danger of this unfortunate conclusion, I append the following cases, being two of frequent instances which I see of these lesions, so latent as to have been entirely ignored by intelligent and experienced men, unacquainted with stethoscopic phenomena.

CASE I. I was called into an adjoining county to see a gentleman, who had been ill six weeks, and whose case, his medical attendant informed me, had puzzled him, inasmuch as the symptoms continued without change, and he was unable to discover any organic disease capable of explaining them. I found the patient, a gentleman about fifty years of age, recumbent in his bed. His countenance was good, though rather suffused, and there was nothing in his general aspect to denote particular distress. When interrogated as to his feelings, he complained of a sense of fulness and uneasiness, referred to the stomach; of a frequent inclination to change his posture; of general restlessness; and, of course, absence of sleep. He said that he was quite free from pain, and had suffered none since the beginning of his illness, when he had "rheumatic pains" flying about his chest and shoulders. His pulse was under ninety; his tongue very red, glazed, and viscid: he had no inclination for food, although he took it; nor had he much thirst. There was cough now and then, but it was slight, and unattended by expectoration; and his breathing was so little disturbed as to have elicited no observation.

I immediately suspected the chest, because my hands failed to find disease elsewhere, and Mrs. A. had been

the employment of auscultation. My anticipations were soon realized, by the discovery of fluid in the left pleural cavity, which it nearly filled. Thus, by the interposition of the ear, an obscure case was in a few minutes made easily intelligible; and a treatment adapted to its exact pathology having been rigorously carried out, the patient was, in six weeks more, restored to health.

The pains felt by the patient, at the commencement of his illness, and which, he flattered himself, were only rheumatic, were, no doubt, those of inflammation, (chronic from the first), of the pleura. Taking, however, this simple view of their nature, he treated himself; and sent for medical aid only when he found that he was falling ill in other respects.

There do not appear to have been any of the ordinary prominent symptoms of thoracic disease, and, least of all, of effusion; for, though the patient lay for the most part on his back, he was not elevated on his bed; and was capable of lying equally on his right as on the left side.

By way of contrast with the foregoing case, but as equally illustrative of the value of auscultation, the succeeding history may prove not unacceptable.

CASE II. I was summoned in the night, with unusual importunity, to visit a respectable innkeeper, in Norfolk. I found him suffering exquisite pain in the left side of his chest, which, the patient insisted, more particularly involved the heart, and that he was dying in consequence. He was bolstered up in bed, and was breathing with the greatest difficulty, the inspirations, numerically, being much increased: his countenance was expressive of extreme anguish and alarm; and I counted a pulse of upwards of 120, very weak and small. The least motion, even speaking, aggravated his suffering; and I could obtain answers from him only in a whisper. My impression, upon the first glance, was as unfavourable as possible; but after examining him, as well as his pain would permit, by percussion and auscultation, I was agreeably surprised to find all the organs within the chest, as well as its lining membrane, free from disease.

Seeing, then, that I had a case simply of intercostal neuralgia, or possibly rheumatism, I was at once enabled to calm my patient's terror by the assurance that all would be well; and that I did not despair of obtaining him some relief even before I left the house. Two grains of opium with two of calomel were immediately administered; and large pieces of flannel, wrung out of water as hot as could be borne, were applied to the seat of pain; and, as he had been greatly reduced by venesection twice performed, and other measures of depletion, (for his case had been treated as inflammation of the pleura), I directed wine, and suitable nourishing diet. A grain of opium with one of the acetic extract of colchicum was to be given, as long as the persistence of any pain made it necessary, every eight hours; and five grains of quinine twice a day. In a fortnight from my seeing him, he was well enough to make a journey to Bury, for the purpose of calling upon me.

Bury St. Edmunds, Suffolk, March 1853.

PERISCOPIC REVIEW.

MATERIA MEDICA, PHARMACY, AND THERAPEUTICS.

THE OIL OF THE JATROPHA CURCAS OR PHYSIC NUT AS A PURGATIVE, AND THE OIL AND LEAVES AS A COUNTER-IRRITANT.

Various physicians have at different times made trials with the expressed oil of the *Jatropha curcas*, in the hope that they might be able to find in it a useful purgative; and recently the inquiry has been renewed. A brief summary of the information which we possess on this subject may, in these circumstances, prove interesting to our readers.

All experimenters agree in admitting the purgative properties of the oil; but a remarkable disparity of opinion exists as to the degree of potency, and the uniformity of the effects which it causes.

The *Jatropha curcas* belongs to the Euphorbiaceæ. In Jamaica, the tree, as well as the fruit, goes by the name of *physic nut*, by which name it is likewise described by Christison and others, in treating of the medicinal plants of the family. The fruit is also known as the *nux cathartica Americana*, and *nux Barbadosensis*. The fruit is a violent irritant poison, and numerous cases of accidental death occur in the countries where the tree grows, from children picking up and eating the seeds, as three or four are quite enough to prove fatal. "The oil (*Oleum Jatrophæ Curcadiæ, seu Oleum Infernale*)," says Pereira, "is analogous in its properties to croton oil. It is occasionally used as a drastic purgative. In India, it is used for lamps." Guibourt obtained a purgative oil from seeds described as often rancid; but he must have met with damaged specimens from South America. Seeds gathered at one of the Cape de Verd Islands, were examined by M. Leconet in 1850. Under pressure, they yielded twenty per cent. of a coloured oil, of which ten or twenty drops were enough for a dose. (*Arch. Gén.*, Jan. 1853.) A medicine of middle power, between castor oil and croton oil, seems thus to have been obtained. Dr. Christison, in his *Dispensatory* (third edition, 1848), says that he has found, from many experiments, that one sample, expressed from Barbadoes seeds, acted precisely like castor oil in the dose of ten, fifteen, or twenty drops; but that another, from Jamaica seeds, sometimes caused the same severe sickness and watery evacuations as croton oil; and, at other times, was inert in the dose of thirty drops. The explanation of the varying results is not easily given; but we are inclined to attribute the occasional weakness or absence of purgative properties to the oil having been prepared by heat, or from damaged seeds.

We have not found any particulars of the oil having been used as a counterirritant; but it possesses rubefacient or irritant properties more or less resembling those of croton oil. The leaves possess rubefacient powers. In connexion with the remarks upon this subject contained in our last number (p. 254, et seq.), we subjoin the following passage from *Gray's Sup. to Pharm.* by Redwood, p. 505, ed. 1847:—"The leaves are rubefacient and discutient: warmed and rubbed with castor-oil, they are applied by the natives of India to inflammations when suppuration is wished for."

ointment of MUCUNA PRURIENS AS A COUNTER-IRRITANT.

M. BLATIN proposes (*Revue Médico-Chirurgicale*, Jan. 1853) the substitution of *Mucuna pruriens* (cowhage) for tartar-emetic or croton-oil, as the active ingredient of ointments intended to act as cutaneous irritants. The proportions are, seven grains and a half of the hairs of cowhage to an ounce of lard. The ointment must be rubbed in from ten to twenty minutes; seven or eight grains are usually sufficient. The immediate effect is the production of a sensation resembling stinging with nettles; but the burning sensation and the itching diminish during the friction, and entirely pass off in less than half an hour. The skin generally becomes covered with white flat papule, which soon disappear, leaving a sensation of heat. The effect is due to the mechanical irritation of the hairs. This system of counterirritation has, we are told, produced no inconvenience: children bear it easily. The indications for its employment are the same as for the use of tartar-emetic or croton-oil ointment.

M. Blatin believes cowhage ointment to be a good medium for the endermic application of various substances, such as hydrochlorate of morphia.

ANTISEPTIC PROPERTIES OF IODOFORM: INHALATION OF ITS VAPOUR IN PHTHISIS.

IODOFORM, according to M. Righini (*Jour. de Chim. Méd.*, Feb. 1853), is possessed of remarkable antiseptic and antispasmodic properties. He tried it in a silk manufactory, by distributing vessels containing small quantities, either in powder or diffused in water, through different parts of the establishment; and he found it effectual, with the advantage, moreover, of not incommencing the work people. As a hygienic resource in hospitals, he recommends that it be employed in the following manner.

A soft paste is made, by moderately heating sixteen parts of starch in a sufficient quantity of distilled water, and stirring them with a wooden spatula. Eight parts of iodoform having been added, the mixture will be found to be readily absorbed by filtering paper. The paper prepared in this way is cut into strips three or four inches wide, and suspended in the wards. The iodoform slowly escapes without causing any inconvenience to the inmates. It is most freely liberated in moist states of

the atmosphere. M. Righini recommends iodoform-paper for the purpose of obviating the bad smells and noxious effluvia of slaughter-houses, and also for preserving meat from spoiling.

M. Righini states that the inhalation of iodoform dissolved in ether is of great service in retarding the progress of phthisis.

PEAT CHARCOAL AS A DEODORISER.

The Chemist (January 1853) quotes the following from a letter in the *Bucks Herald* :—

"The offensive drains at the end of the town of Aylesbury, on the Hartwell Road, which have so long been such a nuisance to the inhabitants residing in that part of it, are now rendered perfectly harmless, by the wonderful effects of the filtration of the drainage through a peat charcoal tank. Not only is all the poisonous effluvia arising from them perfectly deodorised, but the drainage, when mixed with the charcoal, becomes a most valuable manure, and pure water is drunk from it. The apparatus consists of a brick tank, sunk in the ground, at the level of the outlet of the sewer, containing a bed of peat charcoal, about two feet in thickness, through which the sewerage passes off, perfectly inodorous, leaving the ammonia, phosphites, and volatile salts with the charcoal.

"One ton of peat charcoal (costing 3*l.*) doubles its value by taking up the sewerage as a deodoriser, and thus becoming a most capital manure; and at the same time all its noxious properties are got rid of, it being without smell. The value of this manure I am now having tested in Buckinghamshire; and I hope, next year, to show some most beautiful crops raised by it. When I first began to persuade the Local Board of Health at Aylesbury to try a peat charcoal tank, they stated that they could not afford to do it, the sewerage not being of any value there, as no one would buy it, the land in that vale being so proverbially rich, that it did not require any manure. I live six miles from thence; but I said, that rather than the experiment should not be tried, I would give them the charcoal, if they allowed me to carry away the produce of the tank, whenever it required refilling, which has to be done there about every month. Another objection was then made as to the expense of the wood necessary for it: this I also gave.

"The result of the experiment has been the most complete success; and no sooner had I arranged to take away the sewerage, than I had two or three offers to take it off my hands. It has therefore ended in my only having the two first emptyings of the tank, the produce of which I have now lying under a shed at Chequer's-court; and we shall, I hope, next year prove its great value for agricultural purposes. I have seen very offensive water perfectly purified, and made drinkable, in five minutes, by being mixed with the charcoal, and passed once through blotting-paper. It is beginning to come into use in the hospitals, where its value will be immense. Bodies placed in it may be kept any time, it acting as a perfect preservative of all animal and vegetable substances. It will also be most important to the shipping interest, that it should be brought into use in the navy, as it immediately deodorises the bad effects of bilge-water, etc., and thus might often be the means of saving the lives of half a crew.—L. A. F. R."

DESTRUCTION OF THE PUERPERAL MIASMA BY HEATED DRY AIR.

Dr. Bush has directed attention to this subject; and the *Medical Times* of Feb. 10th gives (from a German Journal) the following account of his observations:—

"The means employed consist in heating the room to a high degree with dry air. This is effected by round iron stoves placed in the centre of the room, and connected with the chimney by metal tubes. The heat can be raised to 50-60° R. (about 155° F.) This must be kept up for two days, during which time all furniture and utensils are to remain in the room.

"In March 1851, puerperal fever invaded the Berlin Lying-in Hospital with remarkable severity; nearly all the patients suffered, and the Institution was closed for six weeks, during which time there was the most careful ventilation and purification. These means proved insufficient. Upon the re-opening of the hospital, all the new patients became attacked by the disease a few days after delivery. Then the author tried the plan here detailed in every room in the house. The effect was surprising; no fresh attack occurred during the whole summer. The same measures were adopted some time afterwards, and with the same success."

TOXICOLOGY.

POISONING WITH CARBONIC ACID.

In the *Monthly Journal of Med. Science* for March, Mr. J. Law gives the following account of two cases of poisoning with carbonic acid, which occurred under remarkable circumstances.

CASES. On Sunday, January 4th, 1852, Mr. Wright Wilson, of Sheffield, was summoned to the house of George Hall, in Park Hill Lane, called also, from its elevated position, "Sky Edge". Mrs. Hall was extended on her right side on the chamber-floor, close to the bed-side; while her husband was in an easy bent position, also on his right side, on the opposite side of the bed, his head and chest being under the bed. They were both dead, and quite cold. The woman's countenance was mild and placid; the man's bore a slightly uneasy expression. They were in their night dresses, and there was a plaster on the chest of each. With the exception of an abrasion (less than the nail of the little finger, and surrounded neither by redness nor swelling) on the crown of the man's head, no external trace of violence could, on a very careful examination, be discovered. There were slight suffusions on the man's back; but elsewhere the skin of every part of the two bodies was perfectly natural in colour and appearance. The mucous membranes of their mouths and pharynxes were healthy, and free from every kind of odour. The chamber was orderly, everything appearing to be in its place. There was a singular and intolerable smell in the house, strongest in the chamber. The woman had been in the habit of taking laudanum: of this drug two or three drachms were found in the house.

On Monday, January 5th, probably thirty hours after death, Mr. Wilson, by order of the coroner, examined the bodies.

There were no unnatural external appearances. There was congestion of the membranes and sinuses of the brain. Each lateral ventricle contained about 3*ss.* of clear serum. The lungs were gorged with dark blood; the bronchial mucous membrane was slightly inflamed; and there were extensive pleuritic adhesions. The left sides of the hearts were nearly empty; the right contained a quantity of dark half-coagulated blood. The stomachs were healthy; the woman's contained about 3*iv* of thick gruel-like fluid. This fluid, the stomachs, duodenum, portions of the jejunum, and portions of the colons, were given, at the request of the coroner, to Mr. Haywood, professional chemist, to be analysed.

On Tuesday, January 6th, Mr. Wilson, suspecting the drainage, again examined Hall's house, but again without finding any explanation of the catastrophe. In the adjoining yard, however, he perceived a small quantity of smoke issuing from a cesspool, filled with cinders and fecal matter, in a state of smouldering combustion. When the burning mass was disturbed, even slightly, with a spade, it yielded dense volumes of smoke, and a most disgusting smell, resembling that in the house. Knowing that the ground was loose, stony, and permeable, Mr. Wilson communicated his suspicion to the coroner and to Mr. Haywood, that the gaseous products of this combustion had found their way into Hall's house.

It was proved on the inquest, that, on the night of the 3rd January, Mrs. Hall perceived a very disagreeable smell in her house, and that she, assisted by a neighbour, carefully searched for the cause, but found nothing. At this time, the cinders in the cesspool were red hot; but it was not at all suspected that the fire in the cesspool was in any way connected with the impure state of the atmosphere in the house. A straw mattress had been burnt in the cesspool a few days previously. In this way the cinders had been set on fire; but Mr. Wilson could see no trace of the mattress.

MR. HAYWOOD'S STATEMENT. On Wednesday, January 7th, he examined Hall's house in Park Hill Lane, one of the highest and most airy situations in Sheffield. The house stands on a heap of stones, the remains of an extensive quarry; it consists of one sitting-room, with a small pantry on the ground floor, and a bed-room over them; it is about two feet below the level of the ground on the south-western side, on a level with the ground on the east, and somewhat above it on the north-west. In consequence of the loose nature of the ground, the south-west wall has deviated about one foot from the perpendicular, and, in order to make this wall look straight in the inside, boards, extending from the floor to the ceiling, have been placed near it, there being a space of some inches between the two. At a distance of twelve feet from this wall, and in the bed of loose stones on which the house is built, is excavated a cesspool for ashes and night-soil; this is six feet long, five feet broad, and four feet deep; its walls are lower than the surface

of the loose stones, and have little or no mortar; any gases, therefore, generated within the walls of the cesspool, would easily find their way into the bed of stones, and thence through the broken foundation into Hall's house. Mr. Haywood found the cesspool nearly full of *burning* cinders, mixed with faecal matter. The fire had not made much progress previously to the evening of the accident, when, as proved before the coroner, the contents of the cesspool were "one mass of fire". Ashes were thrown upon it, in the hope of extinguishing it; but under a heavy western gale, which sprang up towards the morning of the 4th January, the contents of the cesspool again became a mass of fire. The wind, pent up in the corner where the ash-pit is placed, forced the gases through the loose stones and broken foundation, into the space between the boards and wall of the lower room, thence into the space between the ceiling and bed-room floor, and thence through large holes and cracks into the bed-room itself. In consequence of the chimney and windows being on the eastern side of the house, the strong west wind produced a partial vacuum in the bed-room, and this vacuum drew, while the wind pushed, the gases from the ash-pit into the bed-room. The current of air through the bed-room floor blew out a candle; and, although the combustion had nearly ceased when the examination was made, yet the atmosphere of the room was intolerably offensive and oppressive.

By means of an aspirator, Mr. Haywood passed four cubic feet of air, as it entered by one of the openings in the floor, through a solution of acetate of lead; no discolouration being produced, it was inferred that neither sulphuretted hydrogen nor hydrosulphate of ammonia was present. Another portion was then passed through a solution of nitrate of silver, without producing anything but a brown tint, arising from a small quantity of organic matter; no cyanogen compounds were consequently present. The air in the aspirator contained 1.4 per cent. of carbonic acid gas, with a trace of sulphurous acid, pure air having only a twenty-fourth of this quantity of carbonic acid.

It is usually believed that an atmosphere containing five per cent. of carbonic acid may prove fatal to man. The bed-room and staircase of Hall's house contain 1283 cubic feet of space. As sixty-two cubic feet of carbonic acid, enough to have poisoned Hall and his wife, are produced by the burning of little more than two pounds of cinders, it may be readily understood that more than sufficient to explain the accident must have resulted from the burning of a heap of cinders measuring sixty or seventy cubic feet.

The communication between the burning cinder heap and the bed-room was more complete than between the former and the sitting-room, where a canary, favourably placed opposite the north-west window, was found uninjured. The space between the boards and wall acted as a flue; and, on the night in question, the larger part of the air, which entered the bed-room, passed through the burning cinder heap. The sitting-room had an open fire-place, and a window to the north-west, through which, on that boisterous night, a current of fresh air was driven. The boards were covered with paper, and the communication between the bed-room and sitting-room was cut off by a door at the bottom of the staircase. A little carbonic acid, however, was detected in the sitting-room, coming from behind a corner cupboard placed against the boards, where the paper did not extend.

Three causes prevented the descent of the carbonic acid from the bed-room to the sitting-room:—The door at the foot of the staircase; the rarefied state of the air in the bed-room produced by the west wind; and the condensed state of the air in the sitting-room produced by the wind blowing through the north-west window. If air passed from either of the rooms to the other, it would have passed from the lower to the upper; but this was probably prevented by the open chimney in the former.

A chimney-board in the bed-room was considered to have very much increased the evil; but as the chamber was part of the flue through which the poisonous gases discharged themselves, their current through the chamber, had the chimney been open, would have been more rapid; but there was space enough between the chimney-piece and chimney-board, and through the imperfectly-fitting windows, for the passage of air; and probably the less impure air of the room passed up the chimney to give place to the poisonous products of the cinder heap.

To trace the communication between the ash-pit and the house, the loose stones, with their covering of earth, were removed to a considerable depth. Mr. Haywood found the warm air from the burning cinder heap, passing through and below the broken foundation; and finding also that the oxide of iron on the stones was converted into a sulphuret, he concluded that the hydro-

sulphate of ammonia had, at the commencement of the burning, been driven in that direction, although he could not detect the presence of any of this substance, or any trace of its action on the metals in the house.

There was not the slightest indication of any vegetable or mineral poison in the parts which were analysed.

From the foregoing facts, Mr. Haywood concluded that George Hall and his wife died from inhaling carbonic acid, and other products of the combustion of the burning cinder heap above described.

DEATH FROM CHLOROFORM: INQUEST.

The *Lancet* for March 20th reports an inquest held by Mr. Wakley on March 22nd, at the Lord Wellington, University Street, St. Pancras, on Caroline Baker, an unmarried woman, aged 28, who died in University College Hospital from the effects of chloroform. The inquest-room was crowded by medical gentlemen and others, anxious to hear the result of the inquiry. Mr. J. H. Gould, physician's assistant, said, that on Friday night deceased was admitted to the hospital, suffering from sloughing ulceration of the labia and vagina. Mr. Erichsen directed Mr. White, the acting house-surgeon, to apply nitric acid to the sores. Accordingly, on Saturday morning, she was subjected to chloroform by Mr. White, the acting house-surgeon, who applied it on a piece of lint to the mouth and nose. Soon afterwards, deceased talked wildly and threw her arms about. Suddenly a partial relaxation of the limbs took place, and she became insensible and pulseless. Witness, fearing a fatal result, sent for Mr. Clover, the resident medical officer. Artificial respiration was kept up, galvanism applied, and everything done to resuscitate her, but in vain, as she gradually sank and died. Mr. Clover corroborated the previous witness, and stated that, although not a qualified practitioner, Mr. White was fully qualified to administer chloroform. During four years chloroform had been applied in 1,000 instances in University College Hospital, without one fatal case occurring. The quantity of chloroform administered was at the option of the operator, and generally averaged from half a drachm to a drachm. Professor Erichsen performed the autopsy, and found a fatty degeneration of the heart, and also that death was produced by a paralysis of the heart, consequent upon the application of chloroform. The unfortunate affair was a purely unforeseen accident, for which no one was to blame. Dr. R. Quain fully sustained Professor Erichsen's opinion; and added, that portions of the heart having been handed to him for examination under the microscope, he had found that organ, particularly on the right side, in a state of fatty degeneration. The coroner minutely summed up, commenting upon the great caution that should be observed in the administration of chloroform. The jury retired, and after a brief deliberation returned a verdict, "That the death was caused by paralysis of the heart, produced by the influence of the chloroform, casually, accidentally, and by misfortune": accompanied with the following observations:—"More precaution ought to be used when chloroform is administered, by a person of experience being present during its administration." The coroner fully agreed with the observation of the jury.

CASES OF POISONING WITH TARTAR EMETIC.

The recorded cases of poisoning by tartar emetic are not numerous, a circumstance which suggests the conclusion that this substance is by no means so generally fatal in large doses as many believe. It is a *common drug*—retailed by grocers in many country places, so that in all probability it has often been taken in mistake for Epsom and Rochelle salts.

CASE I. ACCIDENTAL POISONING WITH HALF-AN-OUNCE OF TARTAR EMETIC: SUCCESSFULLY TREATED BY GREEN TEA, TANNIN, ALBUMEN, AND MUCILAGINOUS INFUSIONS.

The following case (reported in the *Amer. Jour. of the Med. Sciences*, for Jan. 1853, by Dr. HARRIS), confirms the statement of toxicologists that recovery is not unlikely to occur even when a very large quantity of tartar emetic has been swallowed. Benefit in the present case may be fairly ascribed to the treatment adopted.

On the morning of 28th Sept. 1852, Dr. —, feeling a little indisposed, took twelve grains of blue pill mass. At half-past two p.m., he took on an empty stomach what he believed to be half-an-ounce of Rochelle salts, with forty grains of bicarbonate of soda, and as much tartaric acid. Immediately afterwards he dined sparingly on ham, the breast of chicken, and tomatoes; and after dinner he ate two ripe figs. In about thirty-five or forty minutes after taking the medicine, he experienced some nausea; but, attributing it to his indiscretion in having

eaten so soon after taking the powder, he resisted the disposition to vomit which every moment became more urgent. In the course of four or five minutes, however, he was obliged to yield to it, and vomited twice very freely, after which he felt relieved. In two or three minutes the nausea and vomiting returned, and he then began to suspect that he had taken the wrong medicine. Instant inquiry was made, and it was discovered that the person who had put it up had mistaken the *antimonii et potassæ tartras*, for the *sodæ et potassæ tartras*. Dr. T. Williamson saw the patient at twenty-five minutes past three p.m., and immediately ordered for him copious draughts of green tea and large doses of tannin. Albumen, infusion of flax seed, and infusion of the slippery elm, were also freely administered. The vomiting, which was very distressing, continued with little intermission till nine or ten p.m. There was, also, very severe purging with most violent cramps of the legs, and slighter ones of the wrists. The first evacuation from the bowels was purely serous: those which followed were of a bilious character, but very loose. There were no cramps of the stomach. When it was thought that the stomach and bowels had been cleared of the poison, an injection containing tincture of opium was given and repeated in a few moments. The injections not being retained, a full dose of the acetate of opium was administered by the mouth. Brandy mint-julep was also freely given, as the patient was very much prostrated. A large sinapism was applied over the epigastric region, and frictions were used to the extremities during the paroxysms of cramp. Iced tea and iced mucilaginous drinks were continued through the night.

29th Sept. The patient passed a better night than could have been expected; was still nauseated, and complained of great thirst, and of some headache. The tongue was moist; there was no abdominal pain or soreness, nor any burning sensation about the stomach. The bowels were twice moved. Iced tea, iced milk, and arrowroot diet were ordered.—30th. There were neither vomiting, nor purging, nor thirst. The same diet and drinks were continued.—Oct. 1st. He rested badly during the night. He had headache, and nausea; the tongue was coated with white fur: but there was no febrile excitement. The iced drinks were continued: toast, coffee, chicken broth, and oyster liquor were also allowed.—2nd. There was some slight irritation of the throat, some cough, but no pain in the chest, and no fever. The patient was allowed full diet. From this date he continued to improve; and on the 13th, he was able to resume his ordinary occupations.

CASE II. FATAL POISONING BY AN OVERDOSE OF TARTAR EMETIC SENT OUT BY A NON-PROFESSIONAL DISPENSER.

The following interesting case is little known. It was published by Dr. E. SKAE of Leven, Fifeshire, in Sept. 1844, in the *Northern Journal of Medicine*, a periodical which appeared monthly in Edinburgh during a short period. We abridge the author's narrative.

On Friday, the 21st Jan., 1842, at three p.m., Dr. E. Skae was hurriedly sent for to visit J. J. On his arrival a few minutes afterwards, he found that the patient had expired. The man was of short stature, of robust habit and body, of about forty-five years of age. From Dr. Skae's personal observation of the deceased during professional attendances, and from facts communicated by his family, the subjoined is made up.

For several years, at a previous period of his life, he had been much addicted to intemperance, and had in consequence been affected with several attacks of delirium tremens: but four years previous to his death he had joined the temperance society, and had, up to the last week of his life, maintained habits of the strictest sobriety. On "Old Hansel Monday" which is observed throughout Fife as a holiday, and which occurred that year upon the 17th January, being the Monday of the same week in which he died, he broke his pledge, and became intoxicated: on Tuesday and Wednesday he continued his debauch: and on Thursday morning with a view to relieve himself, (as he had done before in similar circumstances), he sent to a neighbouring grocer for an emetic which he took. The action of the vomit commenced eight or ten minutes after its exhibition, and was powerful: two or three hours afterwards, profuse diarrhoea followed, and this latter symptom continued with little intermission up to the moment of dissolution, which took place sixteen hours after the emetic had been administered. During the latter part of the day, he had complained very much of pain in his throat, and in the region of his stomach, and he appeared to labour under great general uneasiness and restlessness, with occasional sweating and great prostration of strength. He had been very fretful under his sufferings, and had incessantly importuned his wife and family to send for Dr. Skae, which they

had steadily evaded, from a belief that his complaints were of the same nature as he had formerly endured, and that like them they would gradually abate. At length his impatience became so strong, that he declared he would "go for the doctor himself"; and by an unexpected exertion of his own strength, he contrived to slip out of bed, when he almost instantly fell prostrate on the floor in a state of insensibility. Dr. Skae was then immediately sent for, and, as has been already stated, upon his arrival found the man dead.

As the family attached considerable suspicion to the violent action of the emetic, inquiry was made at the shop where it had been purchased, where the shopman at once admitted, in terms exhibiting no small degree of confidence in his own knowledge of such matters, that he had supplied them with "two drops", or about fifty-five grains, of tartar emetic, as a safe and proper vomit. The body was buried, but was exhumed by order of the authorities. The mucous membrane of the pharynx, œsophagus, stomach, and duodenum, exhibited a dark and injected appearance. The contents of the stomach were analysed, and a large quantity of tartar emetic was obtained from them. The grocer and his shopman were indicted for "culpable homicide". The case was tried at Perth, in the spring Circuit Court of that year; but, in consequence of technical objections, it was carried before the High Court of Justiciary in Edinburgh, by whom the objections were repelled, and the parties were again placed at the bar at Perth, at the autumn Circuit Court. When the case was called, however, the public prosecutor stated that, for various reasons, he did not intend to bring them to trial. Their excellent character, their deep regret for the unfortunate mistake, the entire absence of criminal intention, the probability of death having been accelerated by other causes than the tartar emetic, and the salutary effects of giving the case sufficient publicity being already gained, were stated as the principal grounds on which the prosecution was dropped. The accused were then dismissed, after a forcible admonition from the bench.

CASE III. RECOVERY AFTER SWALLOWING A TABLESPOONFUL OF TARTAR EMETIC. PUSTULAR ERUPTION OBSERVED.

The following case, related by Dr. GLEAVES, U.S., is thus given by Dr. Taylor, at p. 115 of his *Medical Jurisprudence*, ed. 1852:—"A young man swallowed by mistake a tablespoonful of tartar emetic. In an hour after, he was speechless, pulseless, and apparently dying. Although he drank freely of cold water, and irritated his fauces repeatedly with his finger, no vomiting had occurred. During the first three hours, he vomited only two or three times, and the matter ejected was chiefly the warm water taken to favour vomiting. After the lapse of two hours, there was the most violent purging. In seven hours this ceased, and there was great thirst, with a sense of burning pain in the fauces, œsophagus, stomach, and bowels. There was also great irritability of the stomach, and the vomited matters were tinged with blood. On the following day, the vomiting continued, but the purging was arrested. The surface was covered with pustules: there was pain in passing the urine, which was copious. On the third day, the whole of the body was covered with genuine tartar emetic pustules. These began to heal, and the patient to recover, in about two weeks." (*Med. Times*, Jan. 24th, 1846, p. 127.) This is the only case of poisoning by tartar emetic in which pustular eruptions have been observed. It is otherwise remarkable for recovery from so large a dose, considering that but little of the poison could have been expelled in the first instance by vomiting.

PRACTICE OF MEDICINE AND PATHOLOGY.

THE TREATMENT OF EPILEPSY.

There is perhaps no disease which has been more the victim of irrational empiricism, than epilepsy. In 1605, Henricus à Bra published at Arnheim an alphabetical collection of the medicines which had been used in this disease previously to his time. The list, including some substances of a most disgusting description, amounts to two hundred and thirty-five: and we have no doubt that at least as many more have been used since the time when it was compiled.

A few of the remedies which have been vaunted in our own days, merit some attention.

BLOOD-LETTING, both general and local, has been recommended by most writers. Of this, Portal, in his *Observations sur la Nature et le Traitement de l'Epilepsie*, Paris, 1804, says that it is proper in plethoric, hurtful in anæmic subjects; and

that the indications for use will be afforded by the pulse. It is, he says, sometimes necessary to employ depletion before giving tonics; as where the disease is connected with congestion of the cerebral vessels.

Dr. Watson, in his lectures on the *Principles and Practice of Physic*, third edition, vol. i., p. 560, deprecates general bleeding *during the fit*; but allows of moderate local depletion by cupping from the neck or temples, if there be strong evidence of cerebral plethora. In the intervals, it requires often great nicety to determine whether a depletory or a tonic plan of treatment is necessary; but, under the following circumstances, Dr. Watson counsels blood-letting:—"When the patient is young and strong, and full of blood, and not of a particularly moveable temperament; when he has a hard pulse, or any degree of feverishness; when the disorder has supervened upon the suspension of some customary discharge, so that there is an obvious cause of plethora; and when the disease is in its early stage, and the recurrence of the fits has not yet been established: in any or all of these circumstances, it will often be proper to abstract blood from the patient; and it will always be right to purge him actively, and to insist upon an abstinent regimen. When former paroxysms have been preceded by signs of fulness of the head—by headache, for instance, throbbing of the temporal arteries, distension of the superficial veins, a flushed or loaded countenance—you may sometimes, by a timely use of the lancet or the cupping-glass, avert an attack that was apparently impending."

PURGATIVES have been recommended by nearly all authors, from Hippocrates to the present day; and doubtless do good under certain conditions. Among the ancients, hellebore was the principal remedy; and Dr. Copland states it to be useful in the "verminous" or "uterine" varieties of the disease; the powder of the root, or the extract, being given in doses of gr. x, increased to gr. xxx; or the decoction of the leaves or root may be employed. Oil of turpentine, especially conjoined with castor-oil, is praised by Drs. Copland and Watson. The latter physician finds it especially useful in cases connected with the presence of worms: he recommends it in doses of from 3ss to 3i every six hours. It was first recommended by Dr Latham the elder; and, according to Dr. Copland, has been employed successfully by Young (*Trans. of Coll. of Phys.*, vol. v, p. 52), Percival (*Edin. Med. and Surg. Journal*, vol. ix, p. 271), Lithgow (*Ibid.*, vol. xi, p. 301), Prichard, and himself. Aloes was preferred by Galen and some more recent writers; and Dr. Copland thinks it a very useful remedy, in combination, according to circumstances, with chalybeate, stomachic, and cardiac medicines, or with ox-gall or sulphate of quinine, bitter extracts, etc.

BLISTERS have been recommended by various writers; and, according to Portal, are very useful, especially at the commencement of the disease. Successful cases of the treatment of epilepsy by blisters have been related by Charles Pison, Serrao, Morgagni, and Burserius. Sinapisms, cupping, dry-cupping, the cautery, setons, and the moxa, have also been employed.

VALERIAN has, from the days of Galen, enjoyed a high reputation; and Portal appears to place some degree of confidence in it. Its efficacy, however, as of other mere antispasmodics, is now considered very questionable.

NITRATE AND OXIDE OF SILVER have been much used; but a great objection to the use of the nitrate lay in the permanent discolouration of the skin produced by it. The dose is, at the commencement, half a grain in a pill three times a day: and it has sometimes been increased to fifteen grains. Both the nitrate and the oxide for a time retard the fits, and occasionally accomplish cures.

The salts of ZINC, especially the sulphate and valerianate, are, we believe, much used in the treatment of epilepsy. Dr. B. G. Babington, in *Guy's Hospital Reports* for April 1841, states that he sometimes gives thirty-six grains three times a day.

COTYLEDON UMBILICUS. The juice of the cotyledon umbilicus was brought under the notice of the profession by Mr. Salter, of Poole, Dorset, in a paper published in the *Medical Gazette* for March 2, 1849. The dose, as stated in a subsequent communication, was an ounce of the expressed juice, or half a drachm of the inspissated juice. Dr. Joseph Bullar, of Southampton, published in the same journal for May 18, 1849, the results of his experience in the use of this remedy; and adds some very judicious remarks on the necessity of attending to the general health. "It is too well known," he says, "that setting the general health to rights will not alone cure epilepsy; but no remedy can be available if this step is neglected."

Like many other remedies, the cotyledon has not succeeded in the manner evidently expected when it was introduced into practice.

OTHER SPECIFICS—the mere names of which would fill pages—have at various times had their enthusiastic prescribers. From INDIGO and some other medicines we have seen a long suspension of the fits, even in cases where, on dissection, there were found bony spiculae projecting from the inner surface of the skull.

TRACHEOTOMY. The most remarkable proposition for the treatment of epilepsy is that which has been brought forward by Dr. Marshall Hall in his Croonian Lectures for 1852, published in the *Lancet* for April 10th and 24th, and May 8th and 15th. Acknowledging that apoplexy and epilepsy may have their origin in organic disease of the nervous centres or of their vascular structure, he believes that they are mostly the effect of emotions, acting directly, or of irritations, acting diastaltically, on the neck or larynx. These conditions he designates *trachelismus* and *laryngismus*. *Trachelismus*, or compression of the veins by the contraction of the muscles of the neck, he states to be the cause of epilepsy and apoplexia mitior: but apoplexia or epilepsy gravior do not occur, unless *laryngismus* supervenes. "But if *laryngismus* be the essential link between the exciting causes and the apoplexia and epilepsy gravior, it is plain that tracheotomy, in superseding the effects of this condition, must supersede the graver form of those diseases, converting them into the milder respectively. But an essential part of the epilepsy gravior is *general convulsion*; *laryngismus* then is essential to this convulsion; and as tracheotomy supersedes the effect of *laryngismus*, it must supersede convulsion, with the further train of dire affections, in the epilepsy gravior." In support of his views, Dr. M. Hall relates some cases, the accounts of which have been furnished to him: one by Mr. Cane, of Uxbridge; the other by Mr. Mackarsie, of Clay Cross, near Chesterfield. In these, tracheotomy was performed on epileptic patients with alleged success. More lately, the operation has been performed in St. Mary's Hospital; we have heard, however, that the patient has since the operation had a severe epileptic fit.

Dr. Marshall Hall's plan of treatment is one which is not likely to find favour. From his own statement, it does not *cure* epilepsy; and the importance which he attributes to spasmodic contraction of the larynx is far from being proved. He has evidently been led away by exclusive ideas.

The treatment of epilepsy will never be satisfactory until its pathology has been discovered. In a great number of cases at least, we believe that it arises from *blood-disease*. A humoral theory of the affection is adopted by Dr. R. B. Todd, in his *Lumleian Lectures* for 1849 (*Medical Gazette*, May 18, 1849). He suggests that a connexion between this disease and imperfect eliminatory action of the kidneys will be found much more frequently than is now suspected. He believes that the blood-poison from this, from hereditary predisposition, or from other causes, acts by impairing the local nutrition of the encephalon. Other writers hold similar opinions.

We will conclude with briefly stating what appears to be a correct summary of existing knowledge regarding the pathology and treatment of epilepsy.

1. Epilepsy is an assemblage of symptoms dependent on disturbance of the nervous centres, and which may arise from different causes; some of which operate directly, as injuries, or morbid growths; others through the blood, in the form of hereditary or acquired toxæmia; and others again by reflex irritation. Of these, we believe toxæmia to be the most frequent cause of the disease. The relation to epilepsy of osteophytic or other morbid growths pressing on or irritating the brain, remains to be determined. In some cases they may be the direct cause of the epileptic fits: but they may also, with at least equal probability, be regarded as originally arising from the same blood-disease as that on which the epilepsy depends. After their development, they will doubtless render the case incurable, by renewing the irritation on the occurrence of the slightest cerebral congestion.

2. It is absurd to expect a remedy for epilepsy, which shall in all cases cure it. Acting on the view of its being a blood-disease, we may perhaps hope one day to become acquainted with a medicine which shall be as efficacious in its treatment as cod-liver oil is in the treatment of phthisis. In the mean time, attention to hygienic rules, the proper maintenance of the secretions, and the mineral tonics, especially the salts of zinc, with such occasional adjuncts as may be required by the circumstances of the case, must form our chief remedies.

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

SATURDAY, MARCH 19TH, 1853.

FORBES WINSLOW, M.D., President, in the Chair.

GALACTAGOGUE AND EMMENAGOGUE EFFECTS OF MAMMARY IRRITATION. BY JOHN ROSE CORMACK, M.D.

This communication was an abstract of the paper published at p. 254 of last number.

Mr. HUNT had tried mammary irritation by means of sinapisms in amenorrhœa. It had occasionally succeeded; and it had occasionally failed.

Dr. MURPHY asked Dr. Cormack if he recommended mammary irritation in cases of acute suppression of the menses?

Dr. DRUITT had seen amenorrhœa treated by sinapisms in an hospital, a number of years ago; and he recollected that the practice was abandoned in consequence of a young woman having died of ovarian inflammation. On dissection, an abscess was discovered in one ovary; and this, as well as the fatal issue, had—rightly, or wrongly, he was not prepared to say—been imputed to excessive irritation of the mammae by sinapisms.

Dr. CORMACK admitted that the practice might easily be carried to a mischievous or even fatal excess. As regarded the question of Dr. Murphy, he remarked that he had often, with advantage, used mammary irritation in acute suppression of the menses; but in such cases the engorged condition of the uterus required caution, and a combination of measures.

ON SUBACUTE INFLAMMATION OF THE UTERUS IN VIRGIN FEMALES; ITS SYMPTOMS, DIAGNOSIS, AND TREATMENT.

BY T. SNOW BECK, M.D.

The author stated that the symptoms accompanying this disease were seldom referred to their real cause, in consequence of being seated in parts of the body apparently remote from the affection, and from the menstrual function not being otherwise affected than by the increased pain which attended it. The disease usually came on gradually, being indicated by pain in the lumbar region, sides of the abdomen, and inside of the thighs, which at first only existed during the presence of the catamenia. The pains then became more increased, and finally existed permanently in these situations, being greatly increased at the menstrual periods. The catamenia appeared regularly, and were not increased in quantity or in duration; nor were they preceded or followed by vaginal discharge. After a time, varying according to the individual constitution, the general health became affected. The patient became nervous and languid, with pain at the top of the head: had sleepless nights, frightful dreams, waywardness of temper, depressed spirits, impaired memory, great irritability, considerable derangement of the digestive organs, and frequent palpitations of the heart, whilst the pulse was not accelerated. The pains attending this disease were frequently considered to be "an attack of spasms", whilst at other times they simulated disease of some distant organ, and were then known by the name of the disease thus simulated, with the word "hysterical" prefixed. The simulated affections of the brain were especially referred to, and one marked case quoted.

The DIAGNOSIS was considered with regard to:—

Dysmenorrhœa. This, with other appellations, as amenorrhœa, menorrhagia, etc., was considered as only expressing a prominent symptom, and not as being a disease. For this reason, the author would gladly see these terms expunged from the nomenclature of uterine pathology.

Ulceration of the Virgin Uterus. The author was convinced that no such disease had ever been shown to exist; whilst the statements concerning it he believed to be simply a clever trick to gain notoriety. He considered it a painful instance, where the whole profession had been disgraced for individual advantage.

Ovarian Inflammation. The existence of this disease had been greatly overrated; the pain in the erroneously named ovarian region being seated in the walls of the abdomen, and not in that body. This was shown by gentle pressure increasing the pain, but when pressure was increased, so as to affect the ovary itself, this organ was found to be in a healthy state.

Inflammation of the Vagina. This was shown by contrasting the previously detailed symptoms with those indicative of inflammation of the vagina, which were stated to be—pains

in the sacral region, round the hips, down the outside of the thighs, behind the pubis, and in the groins; increase in the quantity, and prolonged duration, of the catamenia; vaginal discharge; fulness, throbbing, or shooting pains in the vagina; tenderness on sitting down; pain on passing the motions; and the sensation called "a bearing down".

The chief CAUSE was considered to depend upon the social habits of our females, who instead of separating from the world during the menstrual periods, enter into its gaieties as usual, and thus, by disturbing the balance of the circulation, laid the foundation for further disease.

In the TREATMENT, much stress was laid upon the importance of ascertaining (a) whether the uterine disturbance was the result of a derangement of the general health, or, (b) whether the general condition of the health was the sequence of an uterine affection which still persisted. In the former, nourishing diet, mild stimulants, gentle exercise, and preparations of iron would be beneficial; in the latter, these remedies would be detrimental by increasing the inflammation, and this remark applied especially to the preparations of iron, which appeared to exert a decidedly stimulant effect on the uterus itself. Mild cases might be treated by rest, absence from excitement, regulation of the bowels, and an alkali with hydrocyanic acid. But, in more severe cases, the application of leeches was indispensable. The leeches might be applied through a small tube, but it was of little practical importance whether they took on the uterus itself, or on the upper part of the vagina. The author had not found either calomel or bichloride of mercury of much service, but, after the acute stage was subdued, the preparations of gold, combined with Indian hemp and camphor, had proved of great advantage. Local applications he considered valueless, whilst nitrate of silver, or other escharotics, he believed, only created further disease instead of relieving what had previously existed.

Dr. MURPHY had listened with pleasure to the first part of Dr. Snow Beck's paper, in which he had very instructively explained many of the cases of so-called dysmenorrhœa. But he had been surprised and pained at hearing Dr. Beck so far forget himself, as to impute dishonourable motives to his medical brethren. The employment of such expressions as he had used was a scandal to the Society. They (the Fellows) did not meet to abuse and vilify each other; but by a candid exchange and collision of opinion to elicit truth. If they differed from each other on certain points—on the present occasion the difference was regarding the signification of the term ulceration—merely a dispute about a definition—they must learn to bear and to forbear, and to respect each other as fellow-labourers, as men equally engaged in the search for truth. He repeated that he had been surprised and grieved at hearing the expressions made use of by Dr. Beck; and trusted that such imputations of base conduct would never again be heard in the Society. He could not refrain from speaking out his mind plainly and warmly on this point, as he felt that the respectability of the Society was at stake, if such language did not elicit a strong protest. With regard to the treatment, he did not think iron likely to prove so injurious as Dr. Beck was inclined to believe. He had found it very useful, on account of the great nervous irritation, and the rapid progress of deterioration of the blood. Strictly antiphlogistic measures, he believed, would fail in the treatment of the disease.

Dr. TYLER SMITH inquired whether Dr. Beck's paper had been submitted to referees in accordance with the laws: for if it had been, he thought that part of the feeling of the Society should fall on the referees, as well as on the author of the paper.

The PRESIDENT. It was submitted.

Dr. TYLER SMITH was sorry to hear it. He could not see any evidence of subacute inflammation of the uterus, in the symptoms which Dr. Beck had detailed. There was a tendency in some to refer everything to the ovary, to the uterus, or to the vagina. He had seen, in the hands of persons thus led away by one idea, prolapsed uterus, and polypi, mistaken for ovaritis.

A somewhat desultory discussion followed, on various points connected with the diagnosis and treatment of uterine diseases, in which Drs. Crisp, Barnes, and Drutt, and Messrs. L. B. Brown, and Greenhalgh, and other Fellows, took part.

Dr. Beck having replied to the various speakers, the meeting adjourned.

EDITOR'S LETTER BOX.

DEPUTATION TO LORD PALMERSTON ON MEDICAL REFORM.

LETTER FROM GEORGE WEBSTER, M.D., TO THE EDITOR.

SIR,—I perceive that in your last number, in the report of the deputation to Lord Palmerston, it is stated that "Dr. Webster, as an old reformer, and one supposed to take rather extreme views, begged to express his entire concurrence in the Bill".

Truth and my own consistency require that this should be corrected. What I said, in addressing his Lordship, was (in effect), "that as the oldest reformer present, except Mr. Wakley, holding what some considered rather extreme opinions, and having presided over and acted with a large section of the profession, my presence there with so many other reformers of different shades of opinion showed a greater degree of unanimity than had prevailed at any former period. That I did not consider the measure which we were met to support as a perfect one; that there were some of its details open to objection, and doubtless there would be some opposition from different quarters; but I trusted his Lordship would take charge of the Bill, and that by his well known influence and his enlarged grasp of mind, he would be able to disarm opposition, by reconciling any conflicting interests, and removing the differences of opinion which might still exist. That though imperfect in some points, I would rather accept the Bill (with the improvements which it might receive in Parliament) as a *very large instalment* of what was due to the profession, and to the public interests, than see an agitation continued which would be detrimental to both."

I hope that Lord Palmerston, after due examination of so important a question, will be induced to recommend the Bill to his colleagues as a Government measure; and that the College of Surgeons will not show any ungracious opposition to the wishes of a large majority in the profession. There are details in the Bill which I trust will be still further modified. The most important of these appears to me to be—

I. The *composition*, election or appointment of the General or Superintending Council.

II. To give power to this Council to appoint a Body of Examiners, independently of the Medical Corporations, to test candidates for practice in *all departments* of medical science.

III. The age at which surgeons and physicians shall be licensed for general practice.

These points will, however, be duly discussed in meetings of the profession and of the Association, which will be called together to support the Bill, and I have no doubt they will also receive ample attention in both Houses of Parliament. In the mean time, I beg the attention of the profession to them.

I am, etc.,
GEORGE WEBSTER.

Dulwich, March 28th, 1853.

DIFFICULTY OF PREVENTING HOSPITAL ABUSES.

LETTER FROM WILLIAM DAVIES, M.D., TO THE EDITOR.

SIR,—In a leading article of the *ASSOCIATION JOURNAL* for March 11th, on "The Growing Abuses of Hospitals and Dispensaries", you mention the Bath United Hospital as an example of the evil system of indiscriminate advice to out-patients. I can assure you that the subject has been formerly, and again lately, under the careful consideration of the medical staff, and also of the committee of that hospital, and that there exists on the part of both those bodies an anxious desire to remedy the evil to the full extent of their power.

I have thought over the subject very carefully; I have discussed it with my professional brethren; and a few weeks since, I brought it under the notice of the committee. The furnishing of advice and medicine gratuitously, to those who are able to pay for them, is a clear and palpable wrong. There is no doubt about the existence of the disease, but there is great difficulty in devising a remedy. It is a wrong to the hospital by improperly applying its funds; it is a wrong to the medical staff by occupying more of their time than is necessary; it is a wrong to the surrounding practitioners, who are thus deprived of a portion of their patients; and it is a grievous wrong to the patients themselves, by tending to break down their feelings of independence and self-respect. About all this, I imagine, there can be no difference of opinion; but when we come to discuss the remedy, numerous

and great difficulties present themselves. I could suggest several modes of cure, either of which would appear feasible enough upon paper; but when you come to apply any of them practically in the out-patient room, their adaptability fails you. The problem is this:—*To furnish the greatest possible facilities for the medical relief of real objects of charity, and to exclude from it those who are in a position to pay for medical attendance.* I would rather that many unfit persons should be relieved at an hospital, than that any of the sick and indigent should be deterred by difficulties from seeking and obtaining admission. No modification of the ticket system that I have yet seen appears to me at all satisfactory—nor do I think that the plan which answers so well for the Destitute Sick Society, in Edinburgh, would be found available in this city as applied to hospital patients. The machinery does not exist.

I am very glad that you have invited attention to the subject, and hope it may be the means of some plan being suggested by which the difficulty shall be overcome. I am, etc.,

WILLIAM DAVIES, M.D.,
Physician to the Bath United Hospital.

Bath, March 1853.

PREVENTION OF HOSPITAL ABUSES.

LETTER FROM JAMES BLACK, M.D., TO THE EDITOR.

SIR,—Coinciding with the truthful remarks in your articles on the abuses and evils attending indiscriminate medical relief, I beg to enclose a copy of one of the Recommendation Papers, which are required to be presented by the applicants before admission at the Bolton Infirmary and Dispensary. As the paper requires the signature of a subscriber to the funds of the Institution or of other authorised persons, perhaps there is as much security taken against any abuse of the charity as can be obtained. The donor of the paper is presumed to be acquainted with, or to have made inquiries into, the circumstances of the applicant for relief.

I am, etc.,
J. BLACK, M.D.

Bolton, March 1853.

TO THE MEDICAL OFFICERS.

GENTLEMEN,—I recommend to your examination the bearer, of , whom I believe to be a proper object of the Charity.

No. of family,	
Weekly income of the patient when in health,	
Do. do. at present,	
Do. of the rest of the family,	
Age,	
How long ill,	

N.B. This recommendation must be delivered on TUESDAYS, THURSDAYS, or SATURDAYS, precisely at Ten o'clock in the Morning; and if the person requires visiting at home, by Nine o'clock.

It having been found that many persons have been admitted who were not proper objects of the Charity, it has been resolved by the Committee, that in future no recommendation shall be received, unless the particulars of this form be complied with.

WEST OF ENGLAND INSURANCE OFFICE, v. MEDICAL MEN.

Taunton, March 19th, 1853.

SIR,—On March 15th, I received a letter from the West of England Insurance Office, Exeter, signed "CHARLES LEWIS, Secretary", requesting an early reply to sixteen questions relative to the health of a patient of mine, who wished to insure his life.

It appears that companies do not assure lives without a medical report; and it remains for the profession to determine whether it will give gratuitous professional opinions to parties who are so well able to pay them, as insurance companies, if there be any truth in their reports of profits and bonuses.

The words in the sub-agent's letter which I have underlined, were underlined in the original; and I shall be obliged by your printing them in italics, as they show the animus of the writer.

I am, etc.,
C. H. CORNISH.

To Charles Lewis, Esq., Secretary, West of England Insurance Office, Exeter.

Taunton, March 16th, 1853.

SIR,—I have this day received from you a printed form containing many questions (to be answered by me) relative to the

health of my patient Mr. —. I shall feel much pleasure in replying to those questions, on being informed by you that the usual fee will be paid to me for so doing. I live by my profession: the information you require is wholly professional: therefore, I require remuneration for it. I am, etc.,

C. H. CORNISH, F.R.C.S.E.

Reply to the above, from the Sub-agent.

Taunton, March 18th, 1853.

MY DEAR SIR,—The West of England Insurance Office has written to me to get Mr. — examined at the expense of the office, before some surgeon, *but not before you*, and I am to pay him his fee. I am, etc.,

To C. H. CORNISH, Esq., Surgeon.

[At page 222 of our number for March 11th, we published the Manchester Medico-Ethical Society's List of Life Insurance Companies "which recognize the principle of remunerating the medical attendant of an applicant for assurance, should his opinion be sought." We are anxious to print a list of those which do not recognize this principle. Who will contribute to this proposed list? The names of non-paying offices ought to be familiar to medical men.—EDITOR.]

LEEDS AND YORKSHIRE ASSURANCE COMPANY.

LETTER FROM J. H. BYWATER, ESQ., TO THE EDITOR.

SIR,—In the ASSOCIATION JOURNAL for March 11th, there is a communication from the Manchester Medico-Ethical Association, in which is given, "for the benefit of the profession at large", a "list of Assurance Companies which recognize the principle of remunerating the medical attendants of applicants for insurance, should their professional opinion be sought by the office". There can be but one opinion as to the great value of such a list to the profession, provided it be correct; but I suspect that at least one company is inserted in this list which has no right to be there.

Some time during the year 1851, I was requested by a patient to fill up a schedule which had been supplied to him (for the purpose of being filled up by his regular medical attendant) by the agent of the Leeds and Yorkshire Assurance Company, in consequence of his having made a proposal to effect an assurance on his life in that office. I transmitted the needful information; and some time after, having seen the office mentioned as one which recognized the principle of remunerating medical attendants of applicants for insurance, I applied for my fee to the agent for this district. A week or more after having made my application, I received the letter which I enclose, from the office at Leeds. I am, etc.,

J. HALL BYWATER.

Knottingley, Yorkshire, March 24th, 1853.

The following is the letter enclosed by Mr. Bywater:—

Leeds and Yorkshire Assurance Office,
Leeds, 13th January, 1852.

SIR,—Mr. Walker, the agent for this Company at Pontefract, has forwarded to me your note of the 3rd instant, on the subject of a fee claimed of the Company by you for a certificate, in the case of Mr. Thomas Burton, whose life was proposed for insurance.

You state that the office is included in a "list of insurance offices, which recognize the principle of medical remuneration". If by this is meant that the office pays for the certificates of the private medical attendants of parties proposing, it is altogether incorrect; and in any case, the publication of the name of the office in any such list, is unauthorized.

The office requires the party proposing to provide, at his own cost, the medical evidence of his attendant, and (as it did in this case) remunerates only *its own medical referee* for the needful examination. I am, etc.,

B. F. SCOTT, Secretary.

J. H. BYWATER, Esq., Knottingley.

INCOME TAX.

LETTER TO THE EDITOR.

SIR,—I, with many others, members of this Branch* of the Association, have wished to have a meeting of the members, to take

* Lancashire and Cheshire Branch of the Provincial Medical and Surgical Association.

into consideration and petition against the Income Tax. Our Local Secretary at Liverpool, Mr. Jones, has written to his colleague, Mr. Hatton, who lives in Manchester, and this worthy functionary refuses to call a meeting; I therefore ask you to kindly inform us, what steps we may take legitimately to record our sentiments against this obnoxious and iniquitous impost, without troubling Mr. Hatton. I am, etc.,

A LIVERPOOL MEMBER.

Liverpool, March 29, 1853.

[In most Branches, upon receiving a requisition signed by a certain number of members, the President is by law obliged to call a meeting. If such a requisition cannot be got up, the presumption is, that a meeting is not generally desired by the members.—EDITOR.]

SPURIOUS TITLES.

LETTER FROM JAMES McBEAN, CLERK TO THE UNIVERSITY OF ST. ANDREWS, TO THE EDITOR.

SIR,—The senatus having ascertained that a Mr. Hugh Hastings, of Cheltenham, is described in the *Medical Directory* as M.D., B.A., St. Andrews; I am directed to request that you will intimate in the next number of your JOURNAL, that no person of that name is either a Doctor of Medicine, or a Bachelor of Arts of this University. I am, etc.,

JAMES McBEAN.

University of St. Andrews, March 28, 1853.

NEWS AND TOPICS OF THE DAY.

SURREY MEDICAL BENEVOLENT SOCIETY, AND THE MEDICAL BENEVOLENT COLLEGE. At a meeting of the Surrey Medical Benevolent Society, held at Reigate, on the 10th March, it was determined to subscribe from the funds of the Society £2,000, towards the endowment of the Medical Benevolent College, on condition that the Surrey Medical Society should have the perpetual right of nomination to certain exhibitions in the school. The Surrey Medical Society was originally established to relieve the wants of the widows and children of its members; and it has appeared to the promoters of the Society, that they could not more effectually secure the objects desired, than by obtaining for the children of members, at a cheap rate, the excellent education which they will receive in the Medical Benevolent College.

ROYAL COLLEGE OF PHYSICIANS. At the usual quarterly meeting of the *Comitia Majora*, held on Monday, the 21st March, the following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College:—Dr. Armitage, Upper Charlotte Street, Fitzroy Square; Dr. Bristowe, North Addington Street, Camberwell.

Dr. Holmes, Great Torrington, Devon; Dr. Somerville, Walsall, Stafford; Dr. Tuke, York; Dr. Bayes, Marine Square, Brighton; and Dr. Thompson, Newark-on-Trent, were admitted Extra-Licentiate.

MULLAR v. SYME. This case was tried last week before a jury in Edinburgh, when the verdict given was in favour of the defendant. We believe that the case was essentially the same as that of *Lizars v. Syme*, tried in July last, when Mr. Syme also obtained a verdict. In Scotland it is not so unusual as it is in England for professional men to wield, offensively and defensively, the expensive weapons of the law.

ADVERTISEMENTS.

Just Published, price 5s.,

On Rheumatism of the Head and EAR, and on SOME FORMS OF HEADACHE in CONNEXION with DEAFNESS. By WILLIAM HARVEY, F.R.C.S., Surgeon to the Royal Dispensary for Diseases of the Ear.

Also, by the same Author,

On the Enlarged Tonsil, and some Affections of the THROAT in RELATION to DEAFNESS. Price 3s. 6d.
London: HENRY RENSHAW, 356, Strand.

Now ready, PART I. 8vo, sewed, price 12s., to be completed in Two parts.

A Text Book of Physiology. By DR. G. VALENTIN, Professor of Physiology in the University of Berne. Translated and Edited from the Third German Edition, by WILLIAM BRINTON, M.D., Medical Tutor in King's College. Illustrated by upwards of 500 figures, on wood, copper, and stone.
London: HENRY RENSHAW 356, Strand.

NEW SERIES.

THE WING WOMAN; AND THE SUCCESS OF MEDICAL IMPOSTORS.

THE veteran practitioner generally reads without surprise, and with but slight emotion, such histories as that which Mr. RICHARDSON has so well written, and which appears in this day's number. The veteran practitioner has been taught in bygone years, by many events within his own sphere of observation, that the popular estimate of medical skill is quite as often erroneous as it is correct. He has, moreover, from a consideration of these events, rightly concluded that this state of matters, however much it may be deplored, is nevertheless not a subject for wonder, from the simple fact that even educated observers, if ignorant of physiology and pathology, are incapable of testing medical knowledge. On the other hand, the accomplished and well-informed aspirant to the responsibilities and emoluments of practice, who has merely tasted the social difficulties and trials of his adopted career, is not likely to think so little or so calmly of the doctress of Wing, and of the other medical impostors of the day who sail to wealth upon the tide of fashionable folly. In fresh, young minds, of refined and honourable mould, the contemplation of such phenomena can hardly fail to excite feelings of discouragement, despondency, and disgust; feelings, too, which, if embittered by the *res angusta domi*, painfully endanger honesty, or cause the ingenuous man, for the sake of his integrity, impetuously to rush out of a profession which he proclaims to astonished relatives to be one which can only keep him from starvation, provided he use it as a garment wherewith to conceal a systematic charlatanism.

Are years of industry and self-sacrifice, are the life-hazards which have been encountered from exposure to pestilential disease and poisoned wounds—are all these to count as little or nothing in the scale of fortune, when weighed against the tinsel glitter of superficial boasting, the artful courting of fashionable leaders or hospital governors, and the practice of the wildest excesses of modern quackery? If the acquisition of money be held as synonymous with good fortune in life, if gold be the only good which this world can offer, then, to answer truthfully the question proposed, we must admit that it is no rare occurrence for flimsy physicians, and medical swindlers of varied type, to reap golden harvests in fields wherein honest labourers of sterling skill can scarcely glean enough to keep the wolf from the door. But there is a brighter aspect of professional life, to which we are about to turn—an aspect which it is wholesome at all times to contemplate, but especially when the poor man sees the emoluments which he had fancied were the reward of a faithful and skilful discharge of duty, flowing past him, in full and rapid current, into the pockets of a Wing woman, a Holloway, or a Henderson. True it is, that we have ever present among us one or many reigning medical delusions, which command the influence and secure the spoils of various sections of the community—the dissipated sons and daughters

of fashion, with minds replete with nonsense, and devoid of sense—the banker, the merchant, and the city Cræsus, with their one idea—or the clergyman or the squire of mere University breeding, whose education has been such as they might have had in the same cloisters centuries ago, and whose training, so far as the acquisition of actual knowledge is concerned, might have admirably fitted them to move in the best circles of heathen Greece and Rome, but which is not sufficient for the Christian pulpit, the British Senate, and the Scientific World of the nineteenth century.

Stop! stop! some one cries; have not many excellent clergymen and many able statesmen come from the classic banks of Isis and of Cam? In truth and soberness, we answer, No, not one! The theology, the science, and the statesmanship of the Universities are sterile, sapless, monkish, and mouldy; and all that can be gained within their walls is—and it is much, we own—a rigid mental discipline. But mental discipline is no more knowledge, than the well-tilled glebe is the waving wheat. In both cases, good fruit can only follow the sowing of good seed, and the diligent weeding of the field. The faithful priest has learned his divinity and his parish economics, under the stimulus of a good conscience, in his own home; and ambition and patriotism have prompted many to educate themselves as statesmen. The prizemen of the public schools and Universities of England, it cannot be denied, take rank in the aristocracy of intellect simply as Mathematicians, Latinists, or Grecians; and, unless they are instructed carefully, by themselves or others, after leaving their scholastic gymnasia, they grow up to be men of deplorably unsound education. The Scottish schools and colleges have undoubtedly been far below those of England in point of scholarship, but they have infinitely surpassed those of England in the amount of available knowledge which they have imparted; and the result has been exactly what might have been expected—that quackeries, which flourish in England, find much less favour among the clergy and home-educated gentry of Scotland. We have not been led unawares into this episode. We have been desirous not to be misunderstood in the remarks already made, or when we now aver that, so long as Latin, Greek, and Mathematics, are the chief portals to University honours and church livings, the education of our clergy and upper classes will continue to be so unsound, as to make it no matter of surprise that many of them should become the partizans of strange doctrines in theology or therapeutics. A reformed system of University education would do more to elevate medicine in general estimation, than any other event which is likely to happen in this country; because it would enable the great body of our clergy, our gentry, our nobles, and our legislators, to appreciate in some degree at least, and through various media, the past progress and the present state of medical science.

In the mean time, it is the fate of the medical profession to be much depreciated and undervalued, and it is the lot of many able and in every way deserving men to be scarcely able to subsist in localities where the ignorant and the

charlatanic grow rich; but, as we said before, rays of purest sunshine may be thrown even upon this gloomy picture. Let it be remembered that when our ministrations are unrewarded by money, we often have the luxury of doing good. Mere wealth is incapable of yielding any substantial happiness during life, or any consolation at death. It is to his unhallowed gains that the deceiving practitioner can alone look for his pleasures; and when the fleeting breeze of popular applause shall have died away, or when he is dead, his kinsmen and his children will blush at the mention of his name. Again, notwithstanding all that has been said, and all that is daily passing before our eyes, we do not hesitate to declare, as the result of a careful survey of the position of an extensive circle of professional acquaintances, that, generally speaking, after a season of probation, the man who has had a competent education, is possessed of a good moral character, of devotion to medical science, and who waits upon the sick with unfeigned kindness of heart, rarely fails to live comfortably, though perhaps seldom affluently, on the rewards of his labours.

Should, however, misfortune overtake the honest medical practitioner, and starvation threaten his family, he must pause before he seek to repair his fortunes by turning aside to quackery. He must, through the thick clouds of all his misery, contemplate the tremendous weight of his responsibilities, and remember that it is a fearful sin to buy bread with the price of human life.

The real position of the medical practitioner as regards his patients, has been forcibly expressed by Sydenham, in the preface to the first edition of his *Observationes Medice*. He says:—

“Whoever takes up Medicine should seriously consider the following points. *Firstly*, that he must one day render to the Supreme Judge an account of the lives of those sick men who have been entrusted to his care. *Secondly*, that such skill and science, as by the blessing of Almighty God, he has attained, are to be especially directed towards the honour of his Maker, and the welfare of his fellow creatures; since it is a base thing for the great gifts of Heaven to become the servants of avarice or ambition. *Thirdly*, he must remember that it is no mean or ignoble animal that he deals with. We may ascertain the worth of the human race, since for its sake God's only-begotten Son became man, and thereby ennobled the nature that He took upon Him. *Lastly*, he must remember that he himself hath no exemption from the common lot, but that he is bound by the same laws of mortality, and liable to the same ailments and afflictions with his fellows.”*

A few words upon a kindred theme struggle for utterance ere we lay down the pen.

To our prosperous colleagues who, after satisfying the necessities of themselves and their households, have yet to spare, we desire to say that the moral integrity of a sorely tried brother may often be saved from temptation, and sometimes from shipwreck, by a little seasonable aid privately administered from the Medical Benevolent Fund of our Association; which, from the advertisement in this day's number, we rejoice to see is obtaining increased support. We may be also permitted to ask whether a man is entitled to preach a stern professional integrity, and at the same time refrain from relieving, as God may give him opportunity, those who suffer through its observance?

NEW MEDICAL JOURNALS NOT ALWAYS SIGNS OF SECTARIANISM.

A new quarterly medical periodical has appeared in Glasgow. In the words of the prospectus, it is intended to be “a medium for recording the many rare and interesting cases of disease, and the valuable practical observations which must necessarily arise from the superior opportunities for medical experience which the city of Glasgow and the surrounding country afford”. The proprietors likewise remark, that “the difficulty in such an undertaking must be, not in obtaining a sufficient number of able contributors, but in selecting what is at once useful, practical, and instructive”. This is probably quite true as regards the literary supplies; but the difficulty in maintaining a periodical intended for a limited class of persons, is to obtain a sale sufficient to pay the paper-maker, the printer, the editor, and the reviewers. Periodicals addressed to the general public, or which are known to be read by thousands of a particular class or profession, obtain, without an effort, a large auxiliary income from advertisements; but a restricted circulation is a fatal impediment to the influx of much revenue from such a source.

We have not made these remarks from a wish to depreciate this new undertaking, but rather that we might say that, notwithstanding the excellence of Number One now before us, and the apparent abundance of editorial resources, permanent success, in a commercial sense, may not be achieved. We hope, however, that our fears may be disappointed; for the tendency of such periodicals as the *Glasgow Medical Journal* is decidedly good. The character of the authors, the science of their contribution, and the spirit which the prospectus breathes, powerfully commend the work to professional patronage. Its quarterly periods of publication, and its moderate size, are such as to prevent its interfering with journals appearing at shorter intervals and of larger dimensions.

That the enterprise has not originated in any narrow sectarian rivalry, is sufficiently clear from the fact that three out of the ten authors of original contributions in the number before us, have joined our Association within the last three months, viz., Dr. J. A. Lawrie, Surgeon to the Royal Infirmary, and Professor of Surgery in the University of Glasgow; Dr. Eben Watson, Professor of the Institutes of Medicine in Anderson's University; and Dr. Robert Mac Gregor, Physician to the Royal Infirmary of Glasgow. And this leads us to remark, that the cordiality and catholic feeling with which the Association is supported in Scotland, is indicated by another striking fact in connexion with the medical literature of that division of the kingdom, viz., that of the six distinguished men whose names appear on the cover of the *Edinburgh Monthly Journal of Medical Science* as its conductors, four belong to the Association—Professor Simpson, an old member, and Professors Christison and Syme, and Dr. Douglas MacLagan, who have recently joined our ranks. These are encouraging features in the present aspect of the medical profession, for they point out that while the laudable ambition of different schools and colleges may support special literary organs, all these organs may work together in harmony, for the peace, prosperity, and unity of the profession.

LECTURE SECOND.

SECOND AND THIRD STAGES OF LABOUR: ERRORS OF MANAGEMENT WHICH MAY BE COMMITTED.*

MR. PRESIDENT AND GENTLEMEN,

I WOULD wish this evening to direct your attention to the next stage of parturition: and, having briefly pointed out the manner in which the child is forced through the pelvis, and the difficulties which oppose themselves, I shall endeavour to prove to you the errors that may be and are committed in the management of this stage—mistakes which too often lead to the most disastrous results.

As soon as the mouth of the womb is completely dilated, or at least when the resistance of the cervix is overcome, a very remarkable change takes place in the expulsive efforts of the uterus. Hitherto nature has exercised the utmost caution in applying the force at her command; and every means has been used to control the power of the fundus uteri, so long as the tissues of the cervix were unfolded and unprepared to yield to it. But now that difficulty is overcome; and we not only find these expulsive muscles exerting a much greater force, but the whole of the respiratory muscles are called in to aid the expulsive effort. Hence the full inspiration which precedes the pain, and the prolonged deep-toned expiration, which has obtained for these pains the old-fashioned but well known appellation of "groanings". This increased power is fully required to effect the object now to be accomplished; the head of the child has to pass through an osseous cavity so irregular in its form, and so limited in its space, as to need it all. It is not easy for the practitioner, who attends an ordinary labour, to realize to the mind's eye the difficulty which is being overcome, or the force necessary to advance the head; but if, in the dissecting or the dead-room, he endeavoured to force the head of a still-born child through the pelvis, he would soon be convinced of it. It sometimes happens that women die suddenly in this the second stage of labour; and in the *post mortem* inspection, a very great effort is required to extract the head from the pelvic cavity. I have known it to require all the strength a person could use, before it was accomplished.

Such then being the case when, on the one side, there is great power called into action, and, on the other, great resistance, the utmost ingenuity is required so to regulate these opposing forces, that no injury may arise in the struggle that takes place. The power is still to a certain extent controlled; the liquor amnii may not yet have escaped; and if it has not, it resists, but to a much less extent, the force of the fundus; besides, the amount of force which is used is accurately measured by the resistance. In cases of disproportion, where the resistance is great, the contractions of the uterus, at first vigorous and powerful, become afterwards weaker, return at longer intervals, and sometimes cease altogether until the effects of the struggle have subsided: but if the resistance be only moderate, the pains continue of the same strength, return at equal intervals, and are never suspended. In order, however, to overcome the difficulties presented by the pelvis, an amount of mechanical contrivance is displayed, as necessary as it is beautiful.

To illustrate this, allow me to recal to your attention the peculiar form of the pelvic cavity. You are aware that the inlet and outlet of the pelvis are in planes which, if prolonged, would meet at an angle; or, in other words, that the axis of the brim and outlet intersect at a point within the

cavity. The widest space of the inlet is in the transverse, that of the outlet in the antero-posterior direction. The head of the child enters the pelvis in the axis of the brim, moving downwards and backwards; it emerges in that of the outlet, that is, downwards and forwards. So long as it is passing in the axis of the brim, the inequalities of the pelvic cavity oppose themselves; when entering that of the outlet, the soft tissues which close it are the chief points of resistance.

We find also, that the form of the pelvic cavity is such that the head in its transit must take a spiral direction. If, for instance, the pelvic cavity be considered as a series of planes, it will be found that the widest space in each plane, as we descend, changes from the transverse to the antero-posterior measurement: the head in its descent, therefore, must describe a spiral curve, and the pelvic cavity becomes a kind of female screw.

The advantage of this formation must be obvious; the very inequalities of the pelvis, which are designed to support the superincumbent viscera, are so arranged, that they also form a mechanic power to aid the passage of the child. It serves also another purpose—it obliges the head to assume that direction which is most favourable for its expulsion. The most common position which the head presents when it enters the pelvic cavity is that in which the occiput lies anterior to the transverse axis; this is also the most favourable for expulsion, because the back of the head has to glide only a short distance along the curve, in order to pass beneath the arch of the pubis, and afford room for the anterior part to complete its descent. It sometimes happens, however, that the head presents differently. The forehead, for instance, may be anterior, and take the place of the occiput: if the head continued to descend in that direction, it must be forced very much lower down before any portion could leave the pelvic cavity; and being still in the axis of the brim, would be strongly resisted by the coccyx and perineum, the coccyx especially, and the muscles attached to it, powerfully opposing themselves. But the screw-formation of the pelvis generally prevents this; because, as the head descends, the occiput, which lay posterior to the transverse axis at its entrance, is rotated forwards along the curve until it becomes anterior to it; thus securing the important advantage that, no matter what may be the direction of the head at the brim of the pelvis, it must assume, on its transit, that which is the most favourable for its expulsion.

The same rule applies to other presentations than that of the vertex. The face, for example, may present; and if so, the chin lies forwards, just as the occiput in the former instance; consequently, the chin has only a short distance to pass before it escapes under the arch of the pubis, in order to give room for the remainder of the head to emerge from the pelvis. The chin, however, may be directed backwards in the first instance; and if it continued so, the cranium, which is anterior, would pass along the arch like a wedge, the forehead first, then the parietal portion, which must greatly increase the difficulty of expulsion. The form of the pelvis, however, generally prevents this; because, even in this unfavourable position, the chin is often moved forward in its descent, just like the occiput in occipito-posterior positions.

In preternatural positions the same rule is applicable. If the breech present, the most favourable position for delivery is when the back of the child is anterior, corresponding to the abdomen of the mother; but if this be reversed, so that the back lies posterior to the transverse axis, the sacrum nearly corresponding to the sacro-iliac articulation, then the same rotation takes place as in the former instances; the back is rotated forwards, and the deviation is corrected. Thus it will be seen that the peculiar form of the pelvic cavity, limited in its space and irregular though it be, affords the most striking illustration of mechanical contrivance, and is a noble proof of the design of a master mind, who can make these very difficulties the most efficient means of accomplishing his purpose.

The manner in which the head of the child passes through the pelvis, also deserves attention. It not only seeks the

* This Lecture was delivered before the Medical Society of London, on March 16th, 1853.

widest space, but passes through on the principle of a wedge; its least measurement is first presented to the pelvic cavity, and is forced forward in advance of wider portions. For instance, the antero-posterior axis of the head is never parallel to or coincident with the oblique axis of the brim; it cuts it at an angle more or less acute; the occipital end descends, the frontal rises, and thus it passes through the brim. So also the longest transverse axis of the head does not coincide with the opposite oblique axis of the pelvis; the parietal extremity next the pubis descends lower than that corresponding to the sacrum. Thus the head, as a wedge, is forced into the pelvic cavity, which in many instances it expands to a greater or less extent.

In this brief outline of the mechanism by which the difficulties presented by the human pelvis are overcome, I have endeavoured to use the plainest language, and to address myself rather to those who have not made this subject their study, than to those of my professional brethren who are perfectly conversant with it. I trust, therefore, that they will pardon this superficial detail, as my wish is not so much to enter into the minutiae of this mechanism, as to point out with sufficient clearness where practical errors are too frequently committed.

In the description just given, it is assumed that the pelvis is perfectly well formed, and that no disproportion exists between it and the head. In such a case, assistance or interference is no more needed than in the first stage of a healthy labour. Nature is omnipotent, and therefore there is no occasion for superior skill: the highest sagacity is shown in doing nothing.

But, unfortunately, the pelvis is not always perfectly well formed, and the proportion between it and the head is too frequently deranged by many causes. In the consideration of this subject, it cannot be too strongly impressed upon the mind, that civilisation and its vices bring with them the same penalties here as in other instances; and if, in the study of disease, we can trace its causes to habits which are the result of our artificial existence, so in this natural process of parturition, we find the same causes in operation to deprive it of its proper character. The so-called "natural labour" is no longer natural, and must be viewed as a deviation from normal parturition, just as much as disease is a deviation from health: the one requires aid just as much as the other, and equally needs a sound scientific medical education.

I shall first direct your attention to the more trifling impediments to delivery, and then to those serious obstacles which depend upon disproportion.

The pelvis may be perfectly well formed, and yet the head may, through violence of the pains, be forced into the cavity in such a manner that the frontal or anterior part descends lower than it should. The consequence is, that the longitudinal axis of the head lies obliquely across, and becomes fixed in the pelvic cavity; the head makes no further advance; and, although the pains are quite adequate for the purpose, no progress is made in the labour. The educated practitioner at once recognises and corrects this displacement: nothing is more easy. But let us suppose the woman to be in the hands of an ignorant person, who knows nothing whatever about the positions or displacements of the head; who thinks that she knows a great deal, quite sufficient for all practical purposes, when she can distinguish the head from the breech. Under such circumstances, the case becomes one of difficult labour; the pains continue fruitlessly for hours, until at length, making no impression, they become weaker, return at longer intervals, and perhaps are suspended. The sagacious attendant then decides that assistance is necessary: possibly indulging in scientific language, she may call it a case of uterine inertia, or perhaps a distorted pelvis, requiring the forceps at least to effect the delivery. Assistance arrives; a vaginal examination is made; the position of the head is corrected; the labour rapidly proceeds to its conclusion without any instrumental aid, and exposes and puts to flight this most learned explanation of the cause of delay and the mode of removing it.

It would be well if all such blunders could be so easily and so safely corrected; but, unfortunately, it is otherwise. I shall quote another instance, where mismanagement leads to a very different result: for example, when the face presents. In such instances, when the position is favourable, the chin lying forwards, the delivery is generally easy: when unfavourable, the deviation will correct itself, *or may be corrected*; but if we suppose the case in the hands of the scientific individual before alluded to, the results are pretty nearly as follows. The presentation is unusual: it is not the head, nor the foot, nor the breech: what, then, is it? Frequent examinations are made to solve the mystery; the cheek and part of the face which present, already congested and swollen from the pressure of the pelvis, now become much more so; and if no further injury be done to the child, the presentation is arrested: it cannot alter its direction, and so it remains. Labour continues inefficiently for hours; examination after examination is made; and at length, deciding by the rule of time, the midwife comes to the same conclusion as in every other instance. "Everything that could be done was done; but the birth would not come; therefore, assistance must be obtained." Aid is demanded; the forceps are applied, and the child delivered still born; its face frightfully swollen and disfigured. Thus is one life unnecessarily sacrificed.

Let us suppose a different case—one where the breech descends in place of the head. There are certain cases of male infants where the scrotum has been so compressed as to become greatly swollen. I have known instances where, from constant examinations made to find out what this was, the scrotum has sloughed, and the child has been almost emasculated. Some years ago, a highly esteemed medical friend informed me of a case that had just occurred, which, at the time, I believed to be scarcely credible. A tumour of this kind was discovered by a midwife, who immediately sent for a practitioner. Not well understanding it, he obtained a second opinion: neither, however, were very clear as to its nature; but both were perfectly satisfied as to the delay of the labour. By a very simple process of reasoning, they arrived at the conclusion that this tumour must be the cause; and, therefore, that it should be removed. The operation was performed, and the tumour given to the midwife, who, being very curious to know what it was, closely examined it, and discovered the testes of the child!

Again, there are cases when the breech descends with the back towards the sacrum, in which it is driven down so far that it cannot rotate. An attempt is made to deliver without correcting this error; the limbs and body are brought down; but the great difficulty, the head, remains: this is pressed forwards over the brim of the pelvis, and, being there caught, cannot be moved: powerful but misdirected efforts are made to extract it, but all to no purpose; and assistance is sent for just when it is too late—the child has already ceased to exist.

Let us now turn to the difficulties presented by disproportion between the head and pelvis, constituting what may be truly called "morbid labour". The natural laws which govern parturition are too frequently deranged by morbid causes: for instance, the head may be so enlarged by disease as not to be able to enter the pelvic cavity. Cases have been reported, where the uterus was in action, not for hours, but for days, endeavouring to force the hydrocephalic head into the pelvic cavity; at length it was ruptured; yet, had the existence of this disease been ascertained in time, a trochar would have been sufficient to remove the difficulty, and to save the patient.

The disproportion, however, more commonly exists in the pelvis, because it is so frequently softened by disease. Our civilized habits here play an important part in destroying that beautiful mechanism which nature had contrived for the woman's safety. The osseous system is at birth only in the progress of its development. The supply of the elements of bone to the blood is constantly demanded in the infant and growing child; this is abundantly furnished by human milk, which contains casein in a large proportion. But when the infant receives no milk, or almost none,

reared artificially on starch and sugar, in a hundred forms, and under most high-sounding names—what is the result? The child may grow fat, thus deceiving the parent, and supporting the reputation of the boasted pabulum. Casein is not essential to the formation of fat, but of bone; and the osseous system pays the cost of this mistake; its development is arrested; the bones are softer than they should be, and yield to the forces which act upon them; hence the deformities in those bones which are under such influence. Take, for example, the bones of the limbs which support the body. How many instances of bent knees, curved shins, and crooked ankles, meet the eye of the experienced surgeon in these centres of civilization! So, also, the vertebral column constantly deviates from the correct curve. It was the remark of a very distinguished surgeon, who, in the full career of an extensive practice, had numerous cases brought before him of diseases in females, that, no matter what may have been the derangement for which his assistance was sought, they all agreed in one point—"none of them had straight backs". If, then, the long bones below, and the vertebral column above, give such constant evidence of this unhealthy condition, how can the pelvis escape—the common centre of their motions, acted upon by both, and depending for its strength on the integrity of the arches which the pelvic bones form? The deviations in the pelvis are just as frequent as those of the spine or the ankles; and it is just as liable to deformities.

In all such cases, then (and they are numerous), the argument, that "midwifery needs little education, because parturition is a natural process", totally fails. In the conduct of such labours, education and skill are just as much required as in the treatment of disease; and it is my duty to point out to you the consequences that arise from the neglect of this education.

The deformed pelvis may present difficulties in the brim, the cavity, or the outlet. In the child, the softened bones produce one kind of distortion; in the adult, another; and this, because the line of gravity in each is different. In the child, it falls anterior to the pelvic cavity; in the adult, within it: hence the child can never be said to walk erect: its motions resemble rather those of a man when running, and for the same reason: the runner, by throwing his body forwards, brings the line of gravity beyond the pelvis. The effect on the pelvis of the child is to give it the *ovate* form; because the sacrum is driven down between the thigh-bones, and these, as a counteracting force, press upwards behind rather than upon the pelvic cavity. If the softening take place in the adult, the sacrum is pressed towards the centre of the pelvic cavity, and the thigh-bones push the acetabula upwards and inwards. These combined forces, acting towards a common point within the pelvic cavity, produce that peculiar form called the *cordiform* pelvis. This latter variety is attributed, and in many instances justly, to the disease called "*mollities ossium*"; but I do not think that this is in all cases its cause. It is true, that the deviation in the infant pelvis arises from a want of earthy matter, which is not supplied; while that in the adult is produced by a disease which takes it away: but I believe that, even in the adult, the unhealthy character of the food, and its imperfect digestion, may be such, that the blood fails in its supply of earthy matter, and softening of the bone takes place just as in the child. The pelvis, in such cases, however, will be *cordiform*, and not *ovate*.

Either of these exceptions to the standard pelvis may exist, and yet the uterus may have sufficient power to overcome the difficulty, and to expel the child. A longer time may be required for the purpose; but still they may not demand assistance; all that is asked from the attendant is an extra supply of patience. There are cases, however, where the uterus cannot accomplish its purpose: the difficulty is caused by a distortion which varies with every case; and thus difficult labours form a series, from the slightest to the greatest. With some, the aid of the forceps is sufficient to relieve the mother, and save the child; with others, the difficulty, and consequent danger to

the mother, is so great, that it is necessary to sacrifice the child; and in a third class of cases, even this dreadful alternative fails in its object, and the question presents itself, whether, in such extreme cases, we are justified in destroying one life for the very equivocal chance of saving another? or, in other words, when the risk to the mother from any available operation is nearly equal, whether we should not select that which gives to the child its best chance of escape?

All such cases, which require an operation of any kind to be performed, are admitted to demand also skill and knowledge for its performance; they are considered to be the legitimate property of the educated accoucheur. But it never occurs to those who reason in this way, that these essentials are just as requisite, nay, even more so, to prevent assistance from being demanded, or, if such aid be really called for, to determine precisely the time and the mode of affording relief. In the management of difficult labours, education and skill are required from the moment that labour commences; not when, after days of protracted and useless suffering, ignorance resigns her pretensions. The cases of mismanagement that spring from this mistake, might be named "*legion*". Either inflammation is suffered to proceed to that extent, that it may terminate in very serious sloughs in the vagina, cause softening of the tissue of the uterus, or possibly extend to the peritoneum, and terminate in the death of the patient; or she becomes exhausted by the mere protraction of intense pain, the uterus loses its tone, and flooding is the result. In either case, a life may be sacrificed.

Let us now consider the important part that ignorance plays in promoting such results. The attendant, who knows nothing whatever of the true characters of the case in her charge, has only one rule to guide her as to its nature—the rule of time. It is assumed that the degree of difficulty is in direct proportion to the time which the labour occupies, and to the progress made within that time. In order, therefore, to decide by this rule, labour is suffered to proceed far beyond its ordinary length before it is considered difficult; if any progress happen to be made, a still further time is allowed to determine the degree of difficulty. Symptoms of inflammation or exhaustion are beginning to present themselves, but are unnoticed. One effect, however, cannot escape attention—the action of the uterus becomes feeble, or ceases. It is fortunate if aid is then called for, because the patient may be yet saved; but it may be far otherwise. Stimulants given perhaps to increase the pains, only increase the inflammation; or it may be that ignorance assumes the garb of science, administers ergot of rye, and ruptures the uterus. Thus, before the true degree of difficulty is decided upon, the woman may expire.

It is possible, however, that no advance of the child takes place, although the pains have continued incessantly, not for hours, but for days. This is considered a proof of the greatest disproportion, and assistance is consequently required; but when the consultant arrives, it is just possible that he may find no disproportion at all; that the patient has been suffering all this time from what are called "*false pains*"; and that to remove the cause which produced them, his assistance was needed at the commencement, not at the termination of her sufferings. The case, however, may be most difficult, and the diagnosis so far correct; but under what a combination of risks is he now called upon to interfere. Inflammation may have made such progress, that any operation for delivery becomes most dangerous; he has, therefore, to weigh in the balance this risk against the equal and opposing risk of further delay. It may be that no inflammation is present, but the woman is exhausted from her extreme suffering, and gives every evidence of constitutional shock; the action of the uterus is growing feeble, it is losing its tone; and consequently the practitioner is haunted by the apprehension of a fatal flooding the moment that the placenta separates. Thus it is that those labours which the educated practitioner would at once recognize as needing assistance, the moment it could

be afforded with safety, are suffered to proceed without relief so long, that when it arrives it is useless.

This general outline of the serious consequences which follow the mismanagement of difficult labours, is, I trust, sufficient to convince you of the importance of removing the obvious cause—a deficient education. If time permitted me to examine this question more in detail, the proofs would so accumulate as to become irresistible. I shall only refer to two examples, which will be sufficient for my purpose.

Let us suppose that the impediment exists at the brim of the ovate pelvis: the head has just entered, but cannot pass through it. The moment this difficulty is ascertained, as soon as it is found that the uterus fails in advancing the birth, the intelligent practitioner at once uses means to aid the uterus, because, if the head of the child be suffered to remain long wedged between the promontory of the sacrum and the pubis, the soft parts which are interposed may slough. If this occur, a fistula may be established between the urethra and vagina on the pubic side, rendering the patient's life miserable from the constant dropping of urine; or the slough may be on the sacral side, penetrating the tissues as far as the peritoneum, and giving rise to all the symptoms of ruptured uterus. Such are the consequences that may arise from this neglect. The intelligent being, however, to whom I have alluded, thinks otherwise; sufficient time has not been given to ascertain what Nature can do; she waits and waits. "*Rusticus expectat, dum defuat amnis*". At length she calls for aid, just when it is too late. The injury has been done; and if it should happen that the child is delivered safely by the long forceps, nevertheless the patient does not escape, and the case is very probably quoted as an instance of the injury which this dreadful instrument can do.

If we pass from a difficulty in the brim to one in the cavity of the pelvis, it may arise from two very different causes. The pelvis may be slightly cordiniform, the planes of the ischia being pressed too much inwards, and the ischio-pubic rami too closely approximating. In such a case, time may do much, because the head may be gradually so compressed as to adapt itself to this peculiar form, and the pelvis may expand to a certain degree, so as to allow it to pass. So long, therefore, as the action of the uterus is strong, and any progress is made, there is no occasion to interfere; but if the head cease to advance, if the pains become feeble, and still more, if there be the slightest indication of inflammation or exhaustion, interference becomes immediately necessary, because the constitution of such patients is generally feeble, and will not support the pains of labour when greatly protracted. There is, however, a pelvis of a very different kind, which may equally interrupt and prevent the progress of the child; a pelvis which I have elsewhere described as the *masculine* pelvis. This variety is not often observed amongst the inhabitants of large towns, but is common in a hardy peasantry. Women who have been from their childhood accustomed to masculine exercises, as digging, carrying burdens, lifting weights, etc., are necessarily stronger and more muscular than women generally are. The bones, in their growth, adapt themselves to the difference; they are larger and more ossified, hence the large bony wrists, and the stout but most unpoetic ankles, of these rustics. The pelvis is under precisely the same influence; hence it is much more ossified, and assumes the masculine characters; the pelvic cavity is deeper and more conical than the standard pelvis. In addition to this, the articulations are as firm and unyielding as sutures. It may happen that the large ossified head of a male child is forced into such a pelvis; and, if so, it becomes, in the strictest sense of the term, "*impacted*". The ossification of the cranium being almost completed, it cannot yield sufficiently. The constitution of these patients is always vigorous; the action of the uterus is powerful; the pelvis is like a vice. Hence the great risk to be avoided, is inflammation and its consequences. The cautious practitioner will not interfere too promptly in such cases; his object is to use every means to subdue inflammation, to allow time

for the head to mould itself to this peculiar form, and thus hope for delivery. Should he not succeed, he must perforate.

These two cases are apparently alike cases of impaction. In the former, a successful delivery is accomplished by the forceps; in the latter, it cannot be done. But how is an ignorant person to decide such a question as this? She has but one rule to guide her, which is applied indifferently to all cases; that is, to wait as long as she can, and to do nothing. In either case, therefore, mischief must ensue.

I must now beg your attention to the conclusion of this stage of labour. The expulsive power of the uterus has overcome two of its opposing forces—the fibro-elastic tissue of the neck of the womb, and the osseous cavity of the pelvis: there yet remains a third—the perinæum. The tissues which fill up the pelvic outlet, together with the coccyx, form the chief support of the pelvic viscera: these must now be expanded sufficiently to allow the head to pass. The power that may be called into action for this purpose is very great; because, as the head passes down between the pillars of the pubic arch, they become a fulcrum against which the occipital portion rests, while the frontal descends upon the perinæum; the head thus forms a lever of the third order. Such a power as this would be extremely dangerous, if called into full and uncontrolled action. Lacerations of the perinæum would be the rule, not the exception. Some provision is therefore necessary to avoid such an accident; and here we find nature exercising the same caution, and just as provident in securing a favourable dilatation of the perinæum, as we have already seen in the dilatation of the mouth of the womb. The mucous discharge is greatly increased in the vagina; the perinæum is much more extensible; and a kind of act of dilatation takes place. Such a provision as this would seem sufficient to prevent accidents; nevertheless, we observe a further provision in the manner in which the action of the uterus is controlled. Previously, when the head was passing the pelvic cavity, the full power of the uterus was exerted; but now that it presses on the perinæum, the pains become weaker at first, and do not resume their previous force until the perinæum is completely expanded, and prepared to yield. Then, indeed, the most powerful expulsive efforts of the uterus take place, and the severest and most agonizing pains are experienced by the patient. The head of the child, also, for a long time oscillates, descending and retreating before it presses fully on the perinæum; thus, by diminishing irritation as much as possible, the risk of inflammation is avoided. If, however, inflammation commence in these tissues, we have here, also, an illustration of the agency of the reflex nervous function. The irritated nerves are the messengers to convey the intelligence to their common centre. The action of the uterus is instantly controlled, and sometimes completely suspended. The irritation being thus removed, inflammation subsides; the mucous discharge returns; the perinæum relaxes; the pains resume their original force, and the head is expelled. This is sometimes accomplished completely, more frequently in part; the occiput remaining protruded for some time before it is quite expelled.

This brief outline is sufficient to point out how and where errors are committed. They are errors either from carelessness or from precipitancy. The perinæum may be ruptured because it is not properly supported; or it may be torn because the head is brought too rapidly over it. The former error, carelessness, certainly cannot be charged against the respectable individual to whom I have so often alluded; because, however the midwife—be she man or woman—may err in other respects, she never fails to give the perinæum her most sedulous care. The whole of her obstetric duties are concentrated upon this one point; and her reputation mainly depends upon her efficiency in this respect. She will support the perinæum patiently for hours. When it becomes inflamed, or, in her own language, "*hot and dry*", she greases it with lard, and generally succeeds in saving it in an ordinary natural labour; if the labour become difficult, she generally sends for some one else to lacerate it. The perinæum may be sometimes torn from want of attention; but

it is far more frequently lacerated from precipitancy. On this point, I fear that I cannot confine my strictures to those who have no knowledge of midwifery. It is an old observation, that "a little knowledge is a dangerous thing", and in the case which I am now supposing, a little knowledge is worse than none. When the pains are suspended the cause may be misunderstood; ergot of rye is given, powerful expulsive efforts are excited, and the perinæum gives way. Or perhaps the practitioner may have some skill in the use of the forceps or vectis; he believes faithfully that a great deal of time is lost in waiting for the return of pains which can be so easily assisted: the instrument is applied, and the head brought down upon the perinæum, which, being unprepared, of course gives way. This risk becomes a certainty, if unhappily the accoucheur should imagine that the merit of an obstetric, as of a surgical operation, consists in the quickness with which it is done. To remove a stone from the bladder in a few minutes, is a great proof of surgical skill; to remove the head from the pelvis in the same space of time, is equally an evidence of obstetric rashness; the perinæum is torn to a considerable extent, and a serious injury to the patient is the consequence.

To proceed, however, with the phenomena which we are observing, let us suppose that the head and shoulders of the child have safely passed over the perinæum. The greatest difficulty is overcome; the expulsion of the body and limbs gives no trouble, and consequently receives but little attention. Yet I know no stage in this process which requires more. In order to render this intelligible, permit me briefly to review what takes place. The womb is partially, but not completely emptied of its contents; and that contraction of the fundal muscles now commences, which terminates in a state of permanent contraction. Hitherto the contractions and relaxations have been equal; now the degree of contraction greatly exceeds the subsequent relaxation. As the body of the child passes out, this contraction steadily continues, the lower portion of the womb and cervix closing in successively toward the centre, according as it is emptied. Thus, the order in which these fibres contract is clearly seen; the fundus first, then the body, lastly the cervix. *Pari passu* with these changes in the uterus, a corresponding change is observed in the abdominal muscles. They also contract on the retreating uterus, compress the intestines closely upon it, and by these means the uterus maintains its state of contraction.

If nature were left quite to herself, the body and limbs would, by successive pains, be slowly extruded; and those final efforts which expel the child, would also detach the placenta.

The after-birth might remain loosely in the uterine cavity, or in the vagina, or be expelled with the child; but in any case the risk of hæmorrhage is removed, because, the separation from the uterus being completed, its source is cut off. No draining can occur through its spongy structure; and the more perfect contraction of the uterine fibres prevents any hæmorrhage from the sinuses.

These facts are sufficient to point out the causes of failure, as well as the errors which may be committed in the management of this stage. Some of these causes depend on the constitution of the patient. The contractile force of the uterus may be diminished; hence its relaxations are greater than they should be, and hæmorrhage is the consequence. Or it may happen that the correspondence between the contractions of the uterus, and those of the abdominal muscles, is lost: the latter may continue in a state of contraction, when the former is relaxing; hence the superincumbent viscera are pressed down upon the yielding fundus, a cup-shaped depression is produced, an inverted action is set up, and invagination follows, which may terminate in complete inversion, as sometimes happens in very rapid labours.

Another, and much more frequent cause depending upon the constitution, exists in the abdominal parietes. In the explanation given, it was assumed that these muscles retained their natural strength; and when they do so, they

are quite sufficient of themselves to support the uterus. But far too commonly they are in a perfectly opposite condition: they are almost atrophied: the constant use of stays weakens the tone of these muscles. The intestines are deprived of their proper support, and the natural healthy action of the uterus is deranged: the final contraction of the fundus (a contraction which reduces it to one-tenth of its previous size) is not supported; consequently its relaxation is far too great; hæmorrhage follows; and thus a very obvious cause, easily provided against, may, if neglected, produce the most serious consequences.

The attention of the intelligent practitioner is directed to the expulsion of the body and limbs of the child, just as much as to any other part of the delivery. He is anxious to secure uniform contraction of the uterus; to give it artificially that support which the abdominal muscles cannot afford; and thus to render the expulsion of the placenta as easy a matter as the expulsion of the child. But if the parturient woman fall into the hands of a person without education, without any knowledge of the phenomena of which she is a witness, what takes place? No attention is paid to the contractions of the uterus; the child is, perhaps, drawn suddenly away from the passages, while the fundus is left to itself. The contractions are consequently deranged; the cervix and body may contract first, and the placenta be of course retained. To remedy this, the funis is pulled from time to time, at first gently, then more strongly, until at length, one of two results follow: either hæmorrhage takes place, because the placenta is partially but not completely separated; or the fundus uteri is drawn down and inversion is produced. Thus, by mere ignorance, retention of the placenta may be most unnecessarily produced; by further mismanagement it may be followed by hæmorrhage; and even by violence the uterus may be inverted, and the life of the unfortunate patient be the penalty of misplaced confidence.

Time will not permit me to quote examples to illustrate my argument; but this is the less necessary, because I know that the intelligent practitioners whom I address can call to mind in the range of their experience, sufficient instances to support my statements. I trust, however, that in this account of what takes place in labour, from the opening of the womb to the expulsion of the placenta, I have shown sufficiently that it is not everybody that may practise midwifery; and that a most serious and unnecessary sacrifice of human life may be the consequence of entrusting this natural process to ignorant persons. In my next and last lecture, I shall endeavour to point out the remedy for this abuse; and this will lead to the consideration of the new regulations for obstetric education.

Henrietta Street, Cavendish Square, April 1853.

CASES OF CARDIAC AND ARTERIAL DISEASE.

By FREDERICK J. BROWN, M.D.

CASE I. DILATATION OF THE AORTA COMMUNICATING WITH A FALSE ANEURISM EXTERNAL TO THE THORACIC PARIETES.

ALEXANDER FRAZER, aged 46, a fish-hawker, residing in Chatham, applied to me on 29th August, 1852. His habits were reported to be temperate, and he stated that he never used raw spirits. I learned from him that, during the hopping season of 1850 (which is in September), he was engaged in drawing out a pole, when it suddenly parted from the ground, and he fell flat on his back. He immediately experienced severe pain through the thorax, extending from the middle dorsal vertebrae to the sternum. On returning to his home, directly after the accident, he suffered from a burning "red-hot" sensation within the chest, and a cord-like tightness around the body, on a level with the nipples: cough and dyspnoea supervened. The poor man attributed the dorsal pain, which continued severe, to rheumatism, and did not apply to a surgeon until February 1851, nearly six months after the accident.

Frazer was first seen by Mr. Dulvey, of Brompton next Chatham, on Feb. 19. The report for that date states, that there was an aneurism situated high in the thorax, just below the right sterno-clavicular articulation; and that there was great irritation of the bronchial tubes, with very distressing cough, dyspnoea, and difficult expectoration. He had at this time pain down both arms, and pain in the right breast; and the pain in the vertebral region, the "red-hot" sensation within the chest, and the tightness around the thorax, continued. The prescriptions were, a blister to the chest, and pills of tartar emetic, henbane, and blue pill.

February 26th. The bronchitic symptoms were very much subdued; the action of the heart was greatly increased. The prescriptions were—four leeches to be applied once a week to the aneurismal tumour; tartar emetic ointment to be rubbed beneath the clavicles: and the following pills and mixture:—

Rx.—Pillul. hydrarg. gr. v,
Pulveris digitalis gr. ss,
" scillæ gr. ij,
Extract. hyoscyami gr. v. Misce.
Fiant pilulæ duæ omni nocte sumendæ.

Rx.—Infusi digitalis 3iv,
Tinctur. hyoscyami 3iss,
Liquoris ammoniæ acet. 3iss,
Liquoris antimon. tart. 3ij,
Spir. ætheris nitrosi 3iij,
Mistur. camphoræ 3iv. Misce.

Sumat 3j quartis horis.

March 27th. He was so much relieved, that he could walk to Mr. Dulvey's house (nearly a mile, and mostly up hill) without much trouble. The directions had been fully carried out. The aneurism had not increased in size, but there was still considerable difficulty of breathing. The prescription was the following:—

Rx.—Pilulæ scillæ comp. 3iss,
Antimon. tartatis gr. j,
Pilulæ saponis cum opio gr. x,
Pulveris digitalis gr. ij. Misce.

Fiant pilulæ xxiv, quarum sumat duas ter die.

These pills relieved him very much; and in four or five weeks afterwards, the patient resumed his occupation of a fish-hawker, for the first time since his fall on the back. He continued the pills for about a month, and then Mr. Dulvey lost sight of him until March 1852, when he came to him, begging for a supply of the pills.

Frazer applied to me on August 29th, 1852. I learned that he had attended at the Rochester and Chatham Dispensary for some time. He informed me that a convulsive jumping of his whole body first appeared during the winter of 1851-2; also that his voice had become altered in character; and that he had felt a strong pulsation in the dorsal region. He further stated that a swelling had appeared four months since (about April 30th) in the situation of the third intercostal space on the right side, and that it had increased, and had changed its position. This was probably the tumour, which is described by Mr. Dulvey as being situated about the second intercostal space in February 1851, and which the patient termed "a kernel". It is evident that the tumour had been visible since February 1851, and that its augmentation and change of position occurred after April 30th, 1852. The patient stated that he had spat streaks of blood, but denied that he had ever experienced dysphagia. He had suffered from a sensation of tightness in the throat.

PRESENT STATE. The countenance was pale and anxious, and the muscles of expression were greatly developed. The tongue was bare, red, and dry; the pulse 108, locomotive, and vibratory. Respiration was tranquil, but wheezing. He was not subject to attacks of dyspnoea. The voice was husky. He lay on the affected side when in bed, because of a dragging sensation in the tumour, produced by lying on the sound side. He had pain in both arms, especially the right. There was no œdema of the chest or the arms, nor enlargement of the veins of the thorax. He had no headache or giddiness, nor flatulence. He had cough, with

mucous expectoration. He slept for several hours in the night, but then rose, on account of pain in the tumour and in the right scapula and dorsal spine. He ate and drank fairly, but felt weak. He was not disturbed by dreams.

PHYSICAL SIGNS. There was a conical pulsating tumour, involving the nipple on the right side, of the size of a lemon, and exactly resembling the breast of a virgin. Impulse was felt through the tumour in every direction, synchronous with the heart's action. The pulsation was forcible, and the first and second cardiac sounds were heard in the tumour, with the stethoscope placed over the right half and over the centre; but when the instrument was placed over the portion of the tumour nearest to the mesial line of the body, a deeply seated diastolic murmur was heard at a distance from the ear. The cardiac dullness exceeded four inches square. Cardiac pulsation was plainly visible at the lower border of the sixth rib, and to the left of the nipple. The impulse was heaving and forcible; the rhythm irregular. An occasional systolic murmur was heard at the apex; a double harsh murmur at the lower sternum, principally affecting the second sound; a single sawing diastolic murmur in the proper course of the aorta; a single diastolic murmur in the course of the pulmonary artery, of a harsher character than that heard over the aorta; a double harsh murmur at the top of the sternum, and at each sterno-clavicular articulation; and in the right side of the neck a single, systolic, very rough murmur. There was strong visible pulsation and confused murmur in the left side of the neck (the side opposite to that on which was the aneurism). The loudest systolic murmur was that in the right neck, whilst the loudest diastolic murmur was seated over the second costal cartilage, on the right side, as if this were the aperture of the aneurism.

October 1st. The tumour was noted as being very painful, and increasing in size.

October 13th. He was seized at seven A.M. with sudden swelling and distension of the right breast, as high as the shoulder. The aneurism appeared to have burst beneath the pectoralis muscle. The pulse was weak and irritable. The patient had violent perspiration, succeeded by coldness; and severe pain in the breast. The pulsation continued. The skin became warm in the evening.

October 15th. The upper part of the breast was of a greenish-yellow, and the arm, as low as the elbow, of a violet colour, showing the extent of the extravasation. The pain had been relieved by laudanum. Respiration was sibilant.

October 18th. Œdema of the legs had been present for two days past; and this day there was œdema of the right hand and forearm. The radial pulse was distinct. He suffered pain in the breast, also in the left arm.

October 25th. The countenance was haggard. Large clear vesicles were scattered over the right breast. The distension caused much pain, both in the breast and the right arm.

October 28th. Thin crusts existed in the situation of the vesicles.

November 3rd. The lower extremities were much swollen. There was a dusky redness over the aneurismal tumour, and an ichorous discharge from the surface of the breast. Apprehension was felt lest gangrene should occur.

November 4th. He felt severe pain in the tumour. No relief was afforded by drugs.

November 5th. The tumour was quite black: and there was a mahogany-coloured discharge from the abraded surface.

November 8th. The right hand was livid, as well as œdematous. The pulse was perceptible at the wrist. The patient was occasionally delirious. He perspired. He lay forwards over a pillow placed on a table.

November 9th. He died at two A.M. The attendants heard a sudden noise, and perceived blood rushing out of the right arm. The patient observed that "he was done", laid his head on his folded arms upon the table, and quietly expired. It is said that half a pailful of blood was poured out.

EXAMINATION OF THE BODY, thirty-two hours and a half after death. Rigor mortis was present. There was oedema of the lower extremities, of the right forearm, and of the thoracic parietes. The right breast was prominent and black, but not sloughy. There was a sloughy aperture in the axilla, capable of admitting the little finger, which led to a cavernous space beneath the pectoral muscles.

Heart and Aorta. The thorax was opened on the left side, to permit the heart and aorta to be examined previously to an incision being made through the right breast. The pericardium was totally adherent to the heart. The heart was considerably enlarged, flaccid, and thin; and its parietes were degenerated by greasy change of texture. Soft clots were found in the left ventricle; the right ventricle was empty. Blood was present in the inferior vena cava. The valves on the right side were healthy. There was mahogany staining of pulmonary artery. The mitral valve was much stretched by long, thin chordæ tendinæ; it was not thickened. The aortic valves were destroyed by ossiform changes. Ossiform plates commenced at the orifice, and extended throughout the whole thoracic aorta. The abdominal aorta was not examined. The whole of the ascending aorta and the arch were dilated into a great fusiform aneurism, capable of receiving a very large closed fist. The dilatation stopped at the commencement of the descending aorta; but the coats of this part of the vessel were so brittle as to tear on traction. The arteries arising from the arch were sound. The pneumogastric nerve and the recurrent, on the right side, were found to be in their natural position, and not compressed. The nerves on the left side were not carefully examined.

The lining of the fusiform aneurism consisted of a membrane stiffened by calcareous change, and broken into small plates in various places. The valves had nearly disappeared: they formed low ridges. No rent or ulceration was discovered; but a large-sized finger could readily pass through a smoothly lined channel, about two inches in length, into an aneurism external to the ribs. The opening in the aorta was circular, prolonged, and without any edges: it appeared to lead out through the second intercostal space, on the right side of the sternum.

External Tumour. On making an incision through the right breast, it was found that the nipple constituted the apex of a false aneurism, situated externally to the ribs, and extending from the second to the sixth rib. The second, third, fourth, and fifth ribs, were driven inwards (apparently by the force of the pulsation during life), so as to present a concave surface to the integument, with their convexity towards the lung. The second and fifth ribs were necrosed; and the third and fourth were softened like young pork-bone.

The false aneurism was divided into three loculi by firm fibrinous laminae. Superficial to the loculi was a large quantity of laminated fibrine, which, when removed, permitted of communication between the cells. Laminae, two inches in thickness, occupied the apex of the aneurism (which was situated at the nipple, as before stated). The loculi contained red-coloured serum and recent clots. The loculus seated lowest on the chest was the smallest. The false aneurism had become diffused (see history, Oct. 13th) by an aperture in the superior loculus. The blood had extended up beneath the pectoralis major muscle, and had forcibly thrown upwards the clavicle. Some of the blood had found passage, by a devious course, to the wrist. When the whole of the diffused aneurism, and the proper false aneurism, had been emptied of fibrine and clots, the appearance was that of the cavity of the thorax, on one side, inasmuch as the ribs were concave outwards. The difference between the proper false aneurism and the diffused aneurism was striking: the latter contained no laminated fibrine. The blackness of the nipple was due to discoloration only, and not to gangrene.

Lungs. On removing the ribs, the right lung was found to be considerably wasted; it was emphysematous and oedematous. Moderately firm adhesions existed at the apex, and over the lower lobe. The lung adhered to the

dilated aorta. Some serum was found in the cavity of the right pleura. There was no tubercle. The left lung was emphysematous. Black colouring matter was found in both lungs.

Abdomen. The liver was cinnamon-coloured and fatty. The gall-bladder contained bright yellow bile. The spleen was lake-coloured and firm. The kidneys were enlarged; the capsule was morbidly adherent in parts in the right kidney. The left kidney was much enlarged, indurated, and granular. It contained one large superficial cyst, and numerous minute cysts in one tubular bundle. The descending colon was large, and distended with flatus.

CASE II. DILATATION OF THE LEFT SIDE OF THE HEART, WITH ULCERATION OF THE AORTA.

George Cox, aged nearly 36, a bargeman, residing in Rochester, applied to Dr. John D. Brown, of Strood, on April 29th, 1852. His statement was, that he had been ill only two months, and that he had continued at his occupation up to the date of his application. His habits were not reputed intemperate, and he was not particularly subject to rheumatism; but he had had pains in his arms occasionally.

The symptoms present were dyspnoea, greatly increased by exertion; flushed countenance; and vibratory, large, loose pulse, 104 in number. The physical signs were tumultuous movement of the subclavian arteries, and locomotive, radial, and carotid pulse; extended cardiac dulness, with distant impulse and irregular rhythm; double sawing murmur over the heart, generally loudest at the aortic orifice, and extending up the carotid arteries; the second sound over the pulmonary artery exceedingly strong, and thumping in character, closely resembling a murmur; and a crispy emphysema-sound over the heart, on deep inspiration.

The patient was so much relieved by leeching and the exhibition of blue pill and opium, that he imprudently went away in his barge (though incapable of labour); but he returned to his home on May 12th, when he was again visited.

His condition was found to be greatly deteriorated. The urine was albuminous, and the eyelids were oedematous. The pulse was frequent, and the respiration embarrassed. The murmur at the apex was double, as at the previous examination; but it was single and systolic over the aorta.

May 14th. Oedema pulmonum was detected, and symptoms of uræmia were present on the 19th, but subsided in twenty-four hours, under the use of calomel, with leeching over the kidneys, and blistering at the nucha.

May 21st. The patient's extremities were cold, and his respiration much embarrassed.

May 25th. He died at 4 A.M., having been conscious to the last.

EXAMINATION OF THE BODY, thirty-eight hours after death. There was no loss of flesh or of fat. There was general anasarca, and some serous fluid in the peritoneal cavity; but no hydrothorax.

Thorax. The pericardium contained four or five ounces of sanguineous serum. Old adhesions of the pleura existed on the right side; also on the left side, causing the lung to adhere over the pericardium. There was emphysema of the anterior border of the left lung. Both lungs were oedematous, and easily lacerable. The heart was nearly equal in size to that of a calf: when placed on the table, it sank down like a bladder. The left auricle and ventricle were greatly dilated, and they constituted the whole of the heart that was visible; for the right auricle and ventricle were involuted in the septum and left ventricle, and completely concealed. The parietes of the left ventricle did not exceed half an inch in thickness. The mitral valve was very large, and stained purple, but not diseased. The aorta was the seat of extensive disorganization, viz., granular ulceration beneath the valves, and at their line of junction; ulceration in the pouches; separation of the attachment common to the middle and left segments, so that these segments formed one great valve; dilatation of

the sinus for the left coronary artery, equal to the size of a walnut: augmented calibre of the aorta; two ulcers in the ascending aorta—one situated an inch and a half above the valves, extending in the long axis of the artery, and capable of lodging two ordinary thimbles—the other commencing about two and a half inches above the valves, and capable of lodging one thimble (each ulcer being three times as long as its width). The edges of the ulcers were distinct to the touch; but red granulations nearly filled the cavities. The lining membrane of the aorta was smooth. The aortic valves were incompetent when tested by water. Blood was found in only one cavity of the heart, viz., the left auricle, in which it was liquid. The right auricle was empty, and very small. The right ventricle was small, and enclosed as before stated. The columnæ carneæ were very strong, and the little finger could be inserted its whole length into a diverticulum in the septum, between two such columnæ. The total weight of the heart was probably not more than twelve ounces. The muscular tissue was not visibly degenerated.

Abdomen. The liver was not enlarged. The spleen was turgid. Both kidneys were very weighty, probably four times as much so as natural. The capsules separated easily, leaving smooth surfaces. A large amount of sanguineous serum escaped on slicing the organs. The cortical structure was packed with greyish-white deposit.

Chatham, Kent, March 24th, 1853.

THE CLIMATES OF THE WORLD, IN REFERENCE TO THEIR EFFECTS ON MAN'S GENERAL WELFARE AND DESTINY.

By T. G. HAKE, M.D., Physician to the Suffolk General Hospital.

(Continued from p. 125 of No. for Feb. 11.)

THE continent of America, stretching as it does from pole almost to pole, and embracing an immense breadth of land, offers a striking example of a series of natural climates; while that of Europe, chiefly if not wholly owing to the influence of the Gulph Stream, enjoys a climate which is strictly exceptional. The parallelism of latitude then, so generally indicative of similar inland climates, fails to unite the opposite shores of America and Europe under the same zones. The countries of New York and Spain (situated in 40° north latitude), of the Canadas and France (in 50° north latitude), of Labrador and Great Britain (in 55° north latitude), lie in the same parallels; but the mean temperature of New York (50° F.) equals only that of north Germany and the midland counties; of the Canadas (40° F.) that of Norway, Sweden, and St. Petersburg; and of Labrador (32°) that of the North Cape. Indeed, such is the interference of circumstances, local as well as general, with the climate of a country or even district, that the isothermal line of mean annual temperatures has only a qualified value, and might be extended to the seasons and even months, without fully reducing all the differences which exist to a uniform scale.

It is in vain then to seek for isogenetic zones in the same parallels, or old divisions of the globe into frigid, temperate, and torrid zones; and even the isothermal line, as above stated, is not a strict guide in the inquiry. Countries lying within the tropics present every variety of climate; but though the mean annual temperatures of Europe are individually repeated among the mountain ranges and table lands of Mexico, it does not therefore follow that these two remote regions contain the same isogenetic zones. Experience proves the contrary to hold true. It is the boast of some travellers that man is enabled to live in every quarter of the world, and that in this he stands alone in the animal kingdom; but the physiologist corrects this error.

The native of Europe attains longevity, and his race becomes acclimated in Canada; but his life is shortened, and his race is cut off, in Mexico, and the tropical regions around. On the other hand, the African finds a congenial

climate in these latter countries; he is easily acclimated too in temperate, but perishes in frigid zones. In order, therefore, to map out the habitable globe into isogenetic zones, it would be necessary to institute a series of physiological inquiries, in reference, first, to the welfare of individuals who have migrated from one country to another; and next, to the physical and mental characteristics of their descendants. No other course is competent to determine that this or that climate has its duplicate elsewhere; and that man has a home in which the features of his race, and the productions of his native soil, can be preserved.

The influence of the Gulph Stream, which has made Europe an exceptional climate, blends a group of countries of very different latitudes into one isogenetic zone. The Danes, the Saxons, and the Normans, judging of them in a physical sense, have found a congenial climate in Great Britain, as well as the Celts, who cannot be said to have deteriorated in health during the many centuries they have inhabited this country and Ireland. Therefore, in mapping out an isogenetic zone for England, the countries of Europe, whose shores are washed by the Gulph Stream, and those lying along the coast line from Spain to the North Cape, should be included, besides such others, situated inland, as have from time to time supplied our population, and whose descendants embrace the same hardy races as still flourish in these islands; races with whom an interchange of region might be further made without material alteration in the physiological characteristics of their people. That the native of Great Britain, and his descendants, can live in even the more remote parts of Europe, in the south and east, there is little doubt—though not without change of temperament: but this subject will be illustrated hereafter, when the effects of climates, situated beyond our zone, on the Anglo-Saxon constitution, are examined.

Experience shows that the isogenetic zone of these islands is not confined to the limits thus marked out in Europe, but that it stretches across the ocean to Canada and her dependencies, and that it includes some of the northern states of America, to be specified presently. It is stated by eye-witnesses, that throughout the countries which extend from Newfoundland to the lakes of the American continent—Cape Breton, Prince Edward Island, New Brunswick, Nova Scotia, and the Canadas—the natives of British origin preserve their characteristic features; not acquiring the atrabilious aspect, dark hair and eyes, of the United Statesman, nor his emaciated look, but retaining the fair complexion, blue eyes, and other traits of an Anglo-Saxon descent. Nor is the climate of these countries less favourable to the agriculture than to the man of Great Britain. If the cattle is smaller on the whole than at home, this must not be put to the account of climate, but rather to breed. The beef, unlike that of the States, is usually fine and tender. The horse, if not yet bred equal to the English, is of a good kind, and capable of bearing great fatigue; it is often ridden thirty or forty, or even sixty miles without being fed; and will return in the same manner the next day without injury. The sheep thrive remarkably; and if tended with care, they maintain a rivalry with English flocks; and the same may be said of swine—but these, if not attended to, become long snouted, and tall, more like greyhounds, and if left to range through the woods acquire great swiftness. All kinds of grain cultivated in the mother country thrive and ripen perfectly in these dependencies, and produce heavy crops, which are equal in quality to any in the world. Legumes, bulbous roots, above all the potato, indeed every kind of culinary vegetable, arrive at great perfection; while every sort of fruit known in this country ripens equally well there, and is of excellent quality.

In no country do the inhabitants retain health and vigour to a later period of life than in British America; but the bloom of youth is, generally speaking, sooner lost than in England; a circumstance attributable in some measure to the hard life led in the colony, compared with that of the mother country. And the young arrive at maturity at an earlier period than in England—a physiological fact not to

be disregarded; it is attributable to the forcing character of the climate, and is found to be cognate with a similar phenomenon in the vegetable kingdom. It has been observed already, that the more southern portions of Europe, being outside our isogenetic zone, alter the temperament of the Anglo-Saxon; a change which may be induced in the constitution of a family without any encroachment on type: and more than this, their climates produce the forcing effect alluded to, leading to early puberty in the human species, and in the vegetable kingdom producing a more rapid growth and maturity.

This is true of South Italy in relation to England; and yet more so of Calabria, where vegetation especially exceeds in luxuriance of growth that of adjacent and less southern regions of the same peninsula. In Canada the oldest trees do not appear to have exceeded a growth of two hundred years, judging from the number of rings; and the woodsman buries his axe in them at a blow: while in our own country a thousand years is supposed to be the age of many a tough and venerable oak. This, however, may be fallacious; the influence of a primeval forest on its individual productions has to be learnt. Still, the fact that Canada is more forcing in its climate than this country is indisputable; and it shews that a zone, though practically speaking isogenetic, does not preserve a precisely similar character throughout, but that one zone runs into another gradually.

The most genial climate in British America is that of Prince Edward Island. Fever is unknown there; and those who arrive with ague recover in a few days, often in forty-eight hours, without the aid of medication. Pulmonary consumption is so rare as to be seldom met with; in a word, there are few places where health is enjoyed with so few interruptions as there, a large proportion of the inhabitants dying from the gradual decay of nature. The average mortality is scarcely one in fifty; and large families are almost universal. The atmosphere is free from damp; a foggy day does not occur often throughout the year, the morning sun quickly dispersing the dews.

The climate of Cape Breton is somewhat similar to that of Prince Edward Island, but is visited with heavy fogs, which interfere greatly with its excellence. In New Brunswick and Nova Scotia the winters are severe; as likewise in Lower Canada; but they are milder on advancing further to the south-west, where the country takes a turn towards the lakes. As a general expression, the winter of the Canadas may be said to last about four months. Though the cold is intense for nine or ten weeks, the air, dry and elastic, is free from the chilling moisture of a British winter. It is a season of hilarity to the Canadian: during its continuance he enjoys the exercise of skating, hunting, and driving over the frozen snows; for the air, which is a non-conductor of heat, being frequently without motion, the cold is unfelt. The summer is hot to excess, the thermometer standing at 100 F.; but showers from the south-west, sometimes with thunder and lightning, occur once in seven or ten days, and the wind shifts to the north-west, producing a delicious coolness. At night the air is clear; and the unruffled waters reflecting every visible object in the heavens, the moon, shining with a soft and silver-like brilliancy, exhibits a panoramic scene of the utmost beauty. In autumn the days continue warm, the evenings cool, attended sometimes by slight frosts at night; and there is but little rain. After a time, sunshine, frost, and rain, succeed each other, and the leaves of the forest assume every tint and shade of colour. The Indian summer follows—a brief season of frosts at night and sunshine by day.

It would be out of place to enter here upon the characteristic beauties of these vast regions, but not so to express the hope that they may not be separated from this country to which they naturally belong; forming, as they do, beyond all doubt, a part of one and the same isogenetic zone, and affording a legitimate outlet for our population. There exist other countries to the westward, Wisconsin, Iowa, and parts of Michigan, which, as far as is yet ascertained, belong to the same zone. In these the Englishman retains his fresh complexion, and enjoys the rudest health. Ague oc-

curs in the last, as in Canada, among the newly settled districts, but in the two former fever is unknown.

In the north-east, the states of Maine, and probably New Hampshire and Vermont, ought to be included in our zone, but this is doubtful ground; since in those of Massachusetts and New York, which adjoin, those peculiar features of the United Statesman, or Yankee, which are the effects of a totally different zone upon the organization, are observable in a conspicuous degree, and will be notified hereafter.

It would be useless to enter on the discussion of climates within our own territory in the far west, those of the Oregon and Vancouver's Island. These countries are well known; they have been the seats of commercial enterprise from the establishment of Astoria to the present time, and have been described by the trapper, as well as by the United States expedition: but the tide of emigration has not flowed in that direction; therefore little is to be gained by opening the question of their fitness for British settlers.

Such then is the extent of a zone of like productiveness, of which the British isles form the centre; it stretches over a large portion of Western Europe on the one hand; of British America, including portions of the United States, on the other: in all probability it encircles the northern hemisphere, though in a zig-zag direction, and in a belt of varying breadth.

But the zone here mapped out is continuous. It includes none of those temperate climates between which and itself there is a break; climates attained by elevation above the sea-level, such as exist in the table-lands of those high mountain ranges which are found in torrid zones. The claims of such to be considered as detached portions of our zone will be noticed in another paper.

But the great question for Europeans, especially for the colonizing race, the Anglo-Saxon, is this: Is it possible for the native of our temperate northern zone to cross the equator, and find a zone of like geniality and productiveness, one in every sense isogenetic, in the southern hemisphere? This inquiry has to await a practical solution, for now thousands are annually passing from this country to our antipodes in quest of a new home. Meanwhile, they are utterly ignorant of the grounds on which they proceed, and their fate is to become subjects of a great experiment. I shall show in a concluding paper, that as respects a large portion of the Australasian continent, the question has already in a great measure settled itself; sixty years have sufficed to determine the point, and that with a significance scarcely less emphatic than the solution of a similar question has proved, as to whether the territory of the United States of America is strictly isogenetic with our own zone.

The inquiry into the character of the southern hemisphere will be limited to the more promising countries, and especially to the temperate portions of New Zealand.

After perusing the works of naturalists like Dieffenbach, and the observations of Dr. A. S. Thomson, on the climate of New Zealand, not to mention the important remarks of Cook, and the numerous voyagers, resident missionaries, emigrants, and others, who have uniformly afforded the same testimony in its favour, the general reader, probably, is satisfied that all further inquiry as to its suitability to the English constitution is uncalled for.

The observations of Dr. Thomson on the influence of the North Island, in the production and prevention of disease among emigrants from this country, refer to the nature of the climate, and to the health and mortality among the troops of New Zealand, compared with England and her other colonies. The climate he reports to be unexceptionable; the mean temperature higher, the range of the thermometer less than in England; the atmosphere more moist; its pressure very similar to what has been observed in London; indeed, it appears from him, and the concurrent testimony of many, to have nearly all the excellences, and few, if any, of the defects of the climate of England.

In one year, 1848-9, out of nearly two thousand troops, one per cent. died of disease, and in the following year a still smaller number—giving an average mortality, during

the two years, of $8\frac{1}{2}$ per 1,000; while among the soldiers stationed in Great Britain, the mean annual mortality from disease is 14 per 1,000. Some part of the reduced mortality may be attributed, says Dr. Thomson, to New Zealand being an open country, with no large and densely peopled towns to generate disease. The annual ratio of mortality from fever in New Zealand was 0.3 per 1,000; in Great Britain, 1.4: the number attacked in the former country was 13; in the latter, 75.

But New Zealand enjoys a remarkable exemption, according to the same authority, from febrile diseases; such, when they exist, being generated by filth, and not by the climate or soil. The only fatal case among the troops appears to have been accompanied by internal organic disease. Ague, even in the swamps and low banks of rivers, is unknown. Scarlet fever has appeared in the town of Auckland, but no other eruptive fever. Those affected with pulmonary complaints have been one-third less than among the same class in Great Britain. The number of deaths from the same cause is very low, of which the following table affords a striking proof:—

Stations.	Annual ratio of mortality per 1000 among the troops, from all diseases.	Number of men, out of 1000, attacked annually by pectoral complaints.	Average number of deaths out of 1000 men, during a year, from pectoral diseases.
Malta	18	120	6.0
Ionian Islands	28	90	4.8
Bermuda	30	126	8.7
Canada	20	148	6.7
Gibraltar	22	141	5.3
Cape of Good Hope	15	98	3.0
Mauritius	30	84	5.6
United Kingdom	14	148	8.0
Australian Continent	11	138	5.8
New Zealand	$8\frac{1}{2}$	60	2.7

Not merely the troops, but the sons of missionaries who have been brought up in New Zealand, enjoy a remarkable exemption from consumption—a result which can be attributed, says Dr. Thomson, to no other cause than the climate: an opinion in which he is confirmed by the surgeon of the 65th regiment, Mr. Prendergast.

Diseases of the brain and liver are not more frequent than in England; those of the stomach and bowels are less so; but dropsical effusions are more common; the mild nature of the climate leading to chronic, while that of England, in the same cases, would have led to acute inflammation. Rheumatism is but slightly known; abscesses are less common; but ophthalmia is more frequent than in England.

In the report in question is the following remarkable passage:—"In a memoir which has no other object than simply to record the facts, it may appear out of place to enter into any speculation; but having seen that disease and death are less frequent in New Zealand than in England, the question naturally arises, Is the duration of man's life more extended? I should certainly say that it was, not only from the results adduced in this paper, but also from the circumstance that the mortality among children under five years of age has been found to be very low, and from the genial nature of the climate giving to old men an ease and comfort which no wealth nor artifice can produce in England.

"There is a question which time only can determine: Will the European population, born and brought up in New Zealand, possess the mental and bodily energy of those reared during their childhood in Great Britain? Will not the genial climate, and the ease with which the soil yields its fruits, produce a population similar to that found under the cloudless skies and tropical temperature of the shores of the Mediterranean?"

A climate productive of the advantages thus described, appears almost to exceed the standard sought after; and if one were in search of perfection, of the ideal of a climate, such might no doubt be found in New Zealand.

But, in seeking an isogenetic zone of Great Britain at the antipodes, it is not a question of perfect climate, but of summer and winter like our own; of seasons in which cer-

tain fruits of the earth just ripen, and in which ice and snow lie on the ground. In the northern island of New Zealand, the mean of the coldest month is from 47° to 54° $5'$, while that of London is only 36° $F.$; that of the warmest, 70° $5'$ to 73° $5'$, while that of London is 62° ; that of the year, 57° $5'$ to 64° , while that of London is 50° $F.$: in fact, the climate is rather that of Madeira than that of England—with one great exception, that the wind blows with almost unabating violence, over all the islands of New Zealand, throughout the year: a natural phenomenon which renders the air fresh, and is necessarily productive of health.

The middle island of the New Zealand group approximates much more in its climate to that of England. Perpetual snow covers the vast mountain range which runs along its western coast, and is known to lie on the ground occasionally in the plains; so that, while the summer heat is temperate, as in the west of England, there is also a winter characterized by frost. The southern island, though occupying a higher latitude, enjoys a milder climate than the middle, but has the same characteristics as its neighbour. In these, then, far more than in the northern, are to be found the characters corresponding to our zone; and, as far as human foresight can determine, it does appear probable that an isogenetic zone in the southern hemisphere offers itself to our population—a zone in which the features of the Anglo-Saxon race, at the end of five centuries, might, if the race were preserved pure, be the same as should continue to exist in the parent country.

But to the curious inquirer there are problems of a grave kind yet to be considered on this subject, some of which will be determined in the course of three or four generations, while others must remain unsolved until a far remoter period. I am prepared to show, that the low mortality among children as well as adults, and the extended duration of man's life, are circumstances which, however favourable in themselves, afford no more ground for the conclusion that the northern island of New Zealand is isogenetic with the British Isles, than are Madeira, or Alexandria, or Rio Janeiro, in all which life may be more secure, both in childhood and age, than in this country. At present, as far as observation has found opportunity to penetrate, it is found that the offspring of Anglo-Saxon parents, born in New Zealand, resemble the parent stock, and do not, as in the vast regions of Australia and the United States, degenerate on reaching the age of puberty, but go on to acquire that full development which belongs to the youth of England.

This, then, is satisfactory; the race can be reared and preserved; but is not its purity endangered? is it not certain that it will be extensively blended with the Maori? On the shores of Cook's Straits, this admixture has largely taken place already, from intermarriage with the sailors and the daughters of the soil, and the result is said to be a race superior in beauty to the parents on either side; but such is often the result of a new cross at first, and three or four generations must elapse before the question can be solved, as to whether improvement or deterioration is to be the effect of this intermixture. This, however, may apply only to the states of the northern island, in which the natives abound, and where possession of the soil may give rise to such admixture of the two races. In the middle island, the aborigines are few; they are in the position of labourers, and the land is in the hands of the Anglo-Saxon. In this island, then, perhaps above all other localities in the world, provided such exist beyond the equator, is found an isogenetic zone for the English population.

But here follows a question of a more speculative, but scarcely less interesting description. In the southern hemisphere, though there are certain outward resemblances of climate, at least among its general elements, to the countries of the northern; though the atmospheric, the electrical, and the solar influences are the same apparently, and subject to the same laws of action in both,—it is a curious fact, that isogenetic influences, if such exist in both hemispheres, should have given rise to a flora and fauna so opposite. The islands of New Zealand have been, and are,

explored, yet the number of plants discovered, including marine, scarcely exceeds six hundred species—a scantiness which corresponds with that of the animal kingdom, of which, however, the deficiency is far more striking. The greater number of plants, too, both species and genera, are peculiar to the country; and, although lists of marine mammals, birds, reptiles, insects, fishes, shells recent and fossil, and annulose animals, have been furnished, as yet no terrestrial mammal, except bats, has been found in these islands.

The question, then, which arises, is this: Are the flora and fauna of New Zealand—so different to those of its antipodes—to be viewed as the development of a southern region, which is co-ordinate with an opposite state of the earth's magnetism to that of the northern? and if so, will its effects, so far as they affect organization, prove congenial to the system of living beings deriving their origin within the polar influence of a northern hemisphere? Should this inquiry, aided by science and experience, receive a favourable solution, there is no reason left to doubt the isogenetic character of the middle and south island of New Zealand, in reference to our zone, or that they will prove the most suitable home for the Anglo-Saxon that has yet been colonized by his race.

Bury St. Edmunds, Suffolk, April 1853.

BROW PRESENTATION AS A CAUSE OF DIFFICULT LABOUR.

By J. G. SWAYNE, M.D., Lecturer on Midwifery at the Bristol Medical School.

(Read before the Bath and Bristol Branch, March 24th, 1853.)

CASES of brow presentation are by no means frequent, and on this account, perhaps, have not been much noticed in connexion with difficult labour. In the two following instances, which occurred consecutively in my own practice, the severity and duration of the labour were both much augmented from this malposition. In one, delivery was effected by art, and in the other by the powers of nature.

CASE I was attended, in October last, by one of my pupils, who informed me, when I arrived at the house, that the membranes had ruptured the preceding evening, and that he had been in attendance upon the patient ever since, but that no progress had been made, although the pains were very frequent and severe. I found the right frontal eminence presenting, the head being fully engaged in the brim of the pelvis. The anterior fontanelle was towards the left acetabulum, and the face towards the right sacro-iliac synchondrosis. The finger easily reached the eyes and nose, and also the mouth, which was wide open; the chin, however, was above the brim, and could not be reached. As the head was in this position, notwithstanding that the os uteri had been dilated for some hours, and the pains had been very violent, I proceeded to alter the presentation without delay. Using a blade of a forceps as a vectis, I applied it over the chin; and by co-operating with the pains, brought the chin downwards and forwards, beneath the arch of the pubes, so as to convert it into a complete presentation of the face. The delivery was soon accomplished; but the child was still-born, probably in consequence of pressure made by the instrument upon the funis, which was twice coiled round the child's neck. In this case, the woman suffered for some months from loss of power in the right leg, produced, no doubt, by pressure of the chin upon the nerves of the sacral plexus.

CASE II. The next case I saw a few days afterwards, in consultation with my friend Mr. Leonard, who told me on my arrival, about five A.M., that he had been with his patient all night; that the membranes had ruptured the evening before, but that the labour was very tedious, although the pains were constant and powerful. I found the head rather low in the pelvis, with the face directly behind the symphysis pubis. The head was so firmly fixed in the pelvis that it was impossible to pass the finger sufficiently high to reach the chin, or in any way to alter the position of the head.

We therefore allowed the labour to go on naturally, as the head was forced perceptibly lower by each pain. At last the forehead presented at the os externum, the root of the nose being pressed against the sub-public ligament, and the anterior fontanelle against the border of the perineum. The nose now remained stationary in that position, forming, as it were, the centre of the semicircle described by the rest of the head, whilst more and more of the vertex protruded with each pain. At last the whole was expelled, the vertex first, and then the face. The child was still-born, in consequence, no doubt, of the extreme pressure on the anterior part of the head, as the forehead was enormously swollen, and the whole face much distorted. In this case, the mother recovered without any bad symptom.

REMARKS. Presentations of the brow are intermediate between those of the vertex and those of the face, approaching, however, more nearly to the latter than the former. When the vertex presents, the head is said to be flexed upon the body, so that the chin is close to the chest; when the face presents, the head is extended completely, and the chin is as far removed from the chest as the neck will admit of. In a brow presentation, the head is partially extended, so that one of the frontal bones presents, most commonly either the right or left frontal eminence. At the commencement of labour, the presenting part might be included in a circle, the circumference of which touches the root of the nose on one side, and the great fontanelle on the other. On examining at this stage of the labour, the face would be found usually looking towards one sacro-iliac synchondrosis, and the great fontanelle towards the acetabulum of the opposite side, or *vice versa*. As the head descends lower, and becomes more fully engaged in the pelvis, the mento-occipital diameter will correspond with one of the oblique diameters of the pelvis, and thus will take a position at right angles to that which it occupies in an ordinary case; for then it is parallel to the axis of the pelvic brim, and is perpendicular to these diameters. In a brow presentation, the head is placed in the most unfavourable manner possible for traversing the brim of the pelvis; for the longest diameter of the head (the occipito-mental, which measures five inches) corresponds with the oblique diameter of the pelvic brim, measuring only four inches and a half. It is, therefore, scarcely possible for the head to traverse the pelvis in this position; and if it remains unchanged, the chin may be arrested for some hours at the brim of the pelvis, as in Case I. Nature, however, frequently remedies the difficulty, by causing complete extension of the head, as was done artificially in Case I. The chin descends, and the vertex recedes, so that the face, which before presented itself imperfectly, now occupies in full the superior strait: the case is thus converted into one of ordinary face presentation, which, as a general rule, requires no further artificial assistance, the diameters which face presentations offer being scarcely less favourable than the ordinary ones. In some rare cases, a still more favourable change is effected; the face, instead of becoming completely extended, flexes, and thus a presentation of the vertex is substituted spontaneously for one of the face; but in other instances the chin is arrested at the brim of the pelvis, whilst the posterior part of the head is forced down lower and lower with each pain, as in Case II: this is, however, effected with great difficulty and after much suffering, for a long diameter of the head, namely, the occipito-frontal, comes into relation with the principal diameters of the cavity and outlet of the pelvis; the result is, that compression of the anterior part of the child's head takes place to such an extent as to be, in all probability, incompatible with life.

In the treatment of these cases, it will be found, as a general rule, that manual interference is necessary, provided the malposition is not corrected by nature very soon after the rupture of the membranes. If this does not take place, and the labour is allowed to proceed, the risk incurred by both mother and child will be great; it is therefore necessary not to delay interference, otherwise the head becomes so firmly wedged in the pelvis (as in Case II) that it is scarcely possible to move it in any way; it may even be-

come impacted, and no other resource be left but craniotomy.

Two methods have been recommended for altering the position; the first consists in flexing the head, with a view to bring down the vertex. To do this, it is advised to make steady pressure with the finger upon the forehead, so that it may be arrested, whilst the back part of the head is pressed down by the uterine efforts, and the chin caused to ascend towards the chest. This mode seems very easy in theory, but will be found very difficult in practice; and I agree with M. Chailly in considering it as next to impossible. By pressing on the forehead, we act on the centre, and not upon either extremity of the lever represented by the head, and thus have little or no power. The second method is much more feasible, and will generally prove successful; it consists in bringing down the chin (provided it can be reached) by two fingers in the form of a crotchet; but if it cannot be reached by the fingers, it may be drawn down by means of a vectis. The object of these manipulations is to place the chin beneath the arch of the pubes, and thus to convert the case into an ordinary face presentation.

Clifton, Bristol, March 1853.

CAN EXCESS OR A DEPRAVED STATE OF THE GASTRIC AND PANCREATIC JUICES DECOLORIZE THE BILE, AND SIMULATE FUNCTIONAL DERANGEMENT OF THE LIVER?

By CONWAY T. EDWARDS, Esq., Surgeon.

[Read before the Bath and Bristol Branch of the Provincial Medical and Surgical Association, March 24th, 1853.]

THIS is an important question, in reference to the treatment of persons, who, having resided many years in India, return to England suffering from derangement of the whole digestive apparatus. Under a belief that the liver is the one source of all their sufferings, they naturally seek the advice of medical men who have practised in India, and whom they suppose to be more conversant with the nature and treatment of diseases of that organ, than practitioners whose sphere of occupation has been limited to this country.

"I do not" (observed a practitioner in London, to an officer who had seen an extensive service in India), "I do not give it as an opinion that your liver is affected; I state it as a fact." This gentleman had suffered much from dysentery, and from the "heroic" treatment used to subdue it. He had been invalided for several months, from a casualty produced by a cannon-shot, and had returned to England for his health. The clay-coloured alvine dejections, their want of solidity, and the repeated calls to evacuate the bowels in the day, led him to consult a gentleman whom he had known as a practitioner in India, but who was now established in London.

He was put on a treatment of blue pill, tonics, acids, and alkalies; and with returning summer, came his convalescence. Towards the latter end of last autumn the symptoms reappeared. He consulted a physician nearer home, who pronounced the cause of all these symptoms to be liver.

On this, he communicated with his medical friend in town, who recommended a recurrence to the treatment of the previous spring. But a severe winter was before him; a condition of atmosphere existed inimical to healthy life, and which was incessantly draining the electricity from the system. The treatment which had proved so successful in the spring, failed to produce a single favourable change in the disease. His friend advised him to have his liver examined, and to report the result of the examination.

As he resided in my neighbourhood, he came to me.

There was no tenderness nor fulness in the region of the liver; no tangible hardness of that organ; and no external evidences in the colour of the skin, of the tunica albuginea, or beneath the nails, that any functional, or organic disease of that organ existed. The intestines were filled with flatus;

the motions were loose, frothy, and colourless; and the inclination to pass them frequent, and very urgent. The renal secretion was scanty, and high coloured, and its transit irritated the neck of the bladder; the eyes were bright; the heart's action was healthy; the tongue clean, but rather too red; the function of the skin greatly at fault; the appetite good; but the sleep disturbed and unequal. He dwelt strongly on an intense acidity of the stomach; and believed it to be the cause of his sufferings.

The report was, that there was no organic disease, but functional derangement of the liver, and general debility of the organs of digestion.

The order came to take blue pill until the liver gave evidence of its proper function being restored, and to use the alkaline mixture (which was composed of liquor potassæ and infusion of gentian), as the acidity demanded. The blue pill treatment was continued for nearly two months; and his altered expression, and loss of flesh and spirits, told at once how great had been the failure of the treatment. Not a symptom had been removed, not a suffering mitigated. I advised him again to communicate with his friend; who, in addition to his former prescription, urged the use of the nitro-muriatic acid bath twice a day for two months.

During the whole of this treatment, I never interfered; and as each letter assured the sufferer that the disease must ultimately give way to the plan, he was content to follow it. I think, however, he said to me one day, "You are all wrong about my liver; I begin to doubt if it is liver at all."

An accident at once put an end to the further pursuance of this treatment. It was no less than a dinner party: "I must," said my patient, for so I may now call him, "have these urgent calls to stool arrested. I cannot attempt to visit my friend, with the horrible fear of an urgent call before me!" I could not give him positive assurance that he should not be so troubled; but I deemed it highly probable that he would not, if he could abstain from all food, except bread and chicken, and be content with cold brandy and water, in place of a variety of wines. To this he consented; and I gave him two doses of medicine composed of chalk, chloroform, tincture of opium and cinnamon water; one to be taken directly, and repeated before dinner.

On the following day, he expressed himself greatly indebted for the relief he had experienced from all his symptoms. He had had no stool, had slept better than he had done for many months; and the only troublesome symptom was the immense distension from which he at first suffered, and the consequent dispersion of the flatus. I advised him at once to cease taking the blue pill, and continue the nitro-muriatic acid baths, and those only three times a week; to take the chalk medicine twice a day; to live plainly on roast and boiled meat, eggs, toast, milk, rice, and such simple diet; to walk regularly; and not to give himself a moment's uneasiness about his liver or his stools.

From that hour to this time, he has had no return of his sufferings; the acidity has entirely left him, and the stools are gradually assuming a natural hue.

The question which naturally arises from this case, is this:—To what can the colourless condition of the motions be attributed? If to impaired function, or total arrest of the biliary secretion, are such states compatible with healthy life? Is it possible that an organ of such magnitude as the liver could suffer from arrest of its peculiar function for many months, without producing more serious results than clay-coloured stools? Is it out of the range of probability that the real source of the suffering in this instance may be looked for in an increase of the gastric and pancreatic juices? and that these secretions might be endowed with such an increase of intensity, as to be capable of decolorizing the bile?

It certainly is remarkable, that a long course of judicious treatment failed to produce any beneficial results; and that a treatment which had for its object the neutralization of the acid, and subduing nervous irritability, should be attended in a few days with production of bile of a proper colour.

Bathaston, Bath, March 1853.

LIVING LARVÆ PASSED FROM THE BOWELS OF A MAN.

By JOHN LLOYD, Esq.

It can hardly be doubted that larvæ of various insects are occasionally passed from the human bowels, the ova or the larvæ themselves having been received into the body by the mouth along with water or food. A case of this kind has recently come under my notice, in which I have no reason to doubt the veracity of the statements.

The annexed woodcut* represents a living creature which was brought to me by a man living in this town, who stated that he had passed it from his bowels; and that previously he had passed others of exactly the same description. The man's wife confirmed the statement of her husband. They both ascribed to the "worms" severe abdominal pains to which the man is subject.

The animal lived for several days in water. In general, it was torpid; but at other times it was quite lively, frequently bending itself into a circle, as if trying the game of putting its curious long tail into its mouth. Through the kindness of Professor Owen, I am enabled to state that it is the larva of the *helophilus pendulus*—an aquatic larva.

Dr. Cormack has directed my attention to notices of an analogous case, which he brought before the Medico-Chirurgical Society of Edinburgh, on two separate occasions; viz., on the 2nd of June 1841, and the 8th of March 1843. He informs me that Dr. T. R. Scott, of Musselburgh, near Edinburgh, in whose practice the case occurred, thoroughly investigated it, and was convinced that no deception had been attempted.

The following are the brief notices referred to. "2nd June 1841. At the period for medical news, Dr. Cormack exhibited an animal which had been passed, about ten days ago, from the bowels of a young child, a patient of Dr. Thomas R. Scott, of Musselburgh. The animal was still alive. It appeared to be the larva of a beetle, probably *blaps mortisaga*." (*Edin. Monthly Journal* for 1841, p. 538.) The following notice refers to the same patient. "8th March 1843. Dr. Cormack exhibited two specimens of the larva of the *blaps mortisaga*, which had been discharged *per anum* by a patient of Dr. Scott, of Musselburgh, whom he had lately seen."

Dr. Mason Good tells us that leeches have lived in the stomach; and various reputable authors aver that different non-parasitical reptiles and larvæ of insects resist the action of the stomach, as completely as any of the true intestinal parasites.

Llangefni, Anglesey, March 1853.

ARSENIC IN CHRONIC SCABIES.

By PHILIP HENRY WILLIAMS, M.D.

CASE. I WAS consulted, in February 1852, by H. B., aged 22, who stated that she had been suffering from an eruption during nine successive months. The description clearly indicated scabies; and the appearances on the arms, wrists, fingers, legs, ankles, and toes, left no doubt as to the nature of the disease. There were a few scratched spots on the face, which, although a comparatively rare seat of scabies, appears in chronic cases liable to be affected. The itching was, and had been, commensurate with the extent of the malady. Various applications had been tried without benefit. On the hands and toes several distinct pustules had recently occurred, which, in the words of Dr. Bateman, were "moderately inflamed round their bases, and matured and broke in two or three days; then ulcerated, with increasing pain and inflammation". Hence it would seem that the decidedly purulent species (scabies purulenta) was supervening on the ordinary development. The pustules subsequently appeared on other parts, especially on

the arms and thighs, and remained after the simple eruption had died away. The constitution, at the commencement of the attack, was stated to be good; and at the time the patient came under my notice, the health was not impaired. The catamenia were quite regular. I prescribed sulphur ointment, giving iodide of potassium and sarsaparilla in the usual doses, and compound rhubarb pills at proper intervals. This treatment was continued for a month, with very little success. I then ordered three minims of the liquor potassæ arsenitis to be taken three times daily, in camphor mixture. At the end of three weeks the face became quite free from all traces of the eruption, and at the end of the fourth week the disease was declining over the body generally. The mixture was omitted for a few days, in consequence of slight headache, and was then resumed in the same dose, twice daily. In three weeks from that date, the patient was cured, with the exception of some of the larger pustules, which were not healed until a fortnight afterwards. Poultices of linseed meal were applied to them.

Up to the present time, there has been no return of the malady.

A younger sister of the patient suffered at the same time from simple scabies, which yielded at an early period to sulphur ointment and tonics. A companion of Harriet B. also contracted the disease, which became chronic, and required the same arsenical treatment for its removal.

Worcester, March 30th, 1853.

BIBLIOGRAPHICAL NOTICES.

TREATISE ON OPERATIVE OPHTHALMIC SURGERY. By H. HAYNES WALTON. pp. 628. London: 1853.

THIS—the author's *débat*—is a thoroughly good book and bespeaks him an excellent writer and an able surgeon. Here and there we may have wished for something more; but there is hardly anything which we could desire to omit. In the firmness and simplicity of his instruments, in the skilful selection of his cases for the different operations, and in his judicious medical treatment, we trace the characteristics of a good surgeon. We have no absurd proposals for sucking a fluid cataract out of the eye, or the like wonderful performances which we owe to the ingenuity of our Gallic neighbours; and in several chapters we find an accurate appreciation of those circumstances in the general health of the patient, without attention to which the best planned and most skilfully executed operations will so often fail. In the space at our disposal, a complete review of such a work is impossible; a brief epitome of its chapters is all we shall attempt to give.

The not very necessary historical introduction is followed by a brief chapter on the use of chloroform. In all operations accompanied with much pain, by all means let it be employed; but we agree with Mr. WALTON that it is not advisable to use chloroform in the extraction of cataract; and we would merely remark that a surgeon with a sharp eye, a cool head, and a steady hand, will usually prefer to have the command of his patient's voluntary motions, and to avoid the danger which may arise from his restlessness on awaking from his drunken sleep.

Chapter third, on Ophthalmic Instruments in General, is, as we have said, from the pen of a good surgeon, who knows the value of simple and well made tools, and who takes care to see that his very sponges are in order.

The chapter on Injuries from Mechanical or Chemical Agents contains much sound observation. In the treatment of these cases there is, as our author well remarks, "a wide field open for the exercise of practical skill"; not that of the mere operating surgeon, for the difficulty mainly consists in discriminating the cases which must be treated by depletion from those in which an opposite plan is necessary; those

* The woodcut was done from the larva, which was forwarded to us some weeks ago by Mr. Lloyd.—EDITOR.

in which mercurialization will save, from those in which it will destroy the eye. Rules far too exclusive have been laid down in this matter; here, as elsewhere, each case must be studied for itself; and in our own hands blistering and cinchona (as Mr. Wilde recommends) have been found suitable at one time, calomel and opium at another. Mr. Walton strongly advises the exhibition of mercury *in very small doses*, and of hyd. c. creta in doses of gr. ij to gr. iij thrice a day; he says that "the potency and manageableness of this form of the drug cannot be imagined by those who have not used it". He agrees in what we believe is the general opinion, that evacuation of the aqueous humour is always dangerous and generally useless; but we must take leave most decidedly to differ from him when he says, "I have not been able to satisfy myself of the efficacy of blisters in ophthalmic diseases". If we are sure of anything in practice, it is that in many chronic cases of ophthalmia, of cornitis, and of amaurosis, they have done great good.

Chapter sixth treats of Affections of the Eyelids and Diseases of the Lachrymal Passages. Although our author records two successful cases of his own, he judiciously advises that symblepharon should in general be let alone. Of ptosis he gives some interesting cases; and in describing the operation does not omit the caution, that we should remove the skin as near the brow as may be, lest eversion should ensue. Trichiasis next obtains that full consideration which its importance demands; and we may take this opportunity of expressing our concurrence with Mr. Walton's doctrine, that the so-called distichiasis has no existence; and that the hairs, which seem new, are in reality but misplaced. When these displaced cilia are very numerous, or when chronic disease of their bulbs has rendered them abortive and unnatural, so that the forceps are unavailing, an operation is our only resource; and if the excision of a narrow strip of skin close to their roots is not enough to carry them back from chafing on the eyeball, their follicles must be dissected off. Mr. Walton has, in a number of cases, first reflected the skin upwards, and then, after removing the hair-bulbs, re-united the skin by sutures to the edge of the lid. This very ingenious operation may be performed upon the whole edge of the lid, or confined to a single bunch of offending cilia.

Our author next enters very minutely into the cause of entropium, which he finds to be habitual overaction of the strip of the orbicularis muscle, which lies close to the edge of the lid. His treatment is to dissect this off, along with the corresponding strip of skin, taking care, of course, not to injure the cilia. He has operated in this way with success in about fifty cases.

For the slighter cases of ectropium, excision of the conjunctiva, or of a wedge-shaped piece of the lid, may suffice; for those graver cases which depend on previous disease of the bones we must adopt various plastic operations, which, however, can be explained only by the aid of diagrams and the relation of individual cases.

The chapters on Affections of the Puncta and the Canaliculi, and on Caries of the Orbit, are, like the others, good, but require no special remark. We agree with our author as to the impracticability of making anything like a regular use of the nasal sound.

Chapter ninth contains the very best synopsis we have met with of the various treatments of Nævus Maternus and Aneurism by Anastomosis. The surgeon who has a case for which to select an operation, cannot do better than refresh his memory here. As, however, the matter belongs to general rather than to ophthalmic surgery, we shall not do more than just mention a most interesting case of orbital aneurism by anastomosis, in an infant *two months* old, in which Mr. Walton tied the common carotid with complete success.

A short chapter is next devoted to Mr. Tyrrell's Operation of Dividing the Conjunctiva to prevent its strangling the cornea in purulent ophthalmia. The instrument employed by Mr. Walton for this purpose is a narrow curved bistoury, which is better adapted than a cataract knife for incising the chemosed membrane.

Chapter eleventh treats of Squint. Our author thinks that in ordinary strabismus convergens, only one eye is usually affected; and he argues elaborately that the seeming participation of both eyes is but apparent. This we cannot see that he has proved; and we think, moreover, that the test which he proposes in p. 279, and which we always employ, will disprove his own opinion. Let the patient look at the surgeon with each eye in turn, while the other eye is first covered, and then suddenly exposed, and the obliquity of both eyes will, we venture to think, generally become manifest. Mr. Walton's mode of operating is to introduce the hook through a small opening made close to the lower edge of the tendon, and, raising tendon and conjunctiva on the hook, to divide them both together with one stroke of the scissors. Now and then the operation appears at the time to have failed completely, while in a few days the eyes assume the correct position. If eversion should unfortunately follow, the case ought to be left to itself, as further interference is pretty sure to make matters worse.

In chapter twelfth are discussed Tumours of the Lids, Pterygium, and Growths from the Fibrous Tunic of the Ball. There is a curious case recorded of syphilitic tumours around the orbits; and a very successful and creditable operation for the removal of a large orbital exostosis. A description of the *ocular sheath* prepares the way for the interesting subject of exophthalmos from rheumatic disease of that fibrous funnel, and of the diagnostic marks between this and protrusion of the eyeball from periostitis of the orbit. In the latter case the action of the muscles of the protruded eye will be often quite free, and the swelling will affect chiefly the upper portion of the lids; in the former the ball is more usually fixed, and the tarsal part of the lids principally affected. Rheumatism of the ocular sheath is a most interesting disease, whether it end favourably by gradual subsidence of the severe pain, and retraction of the protruded eye, or unfortunately, by suppuration around the ball, and loss of sight. Chapter thirteenth, which discusses this subject, contains, also, some interesting remarks on the curious cases of protrusion of the eyeball in connexion with anæmia and disease of the thyroid gland.

In chapter fourteenth, our author agrees with Mr. Bowman, that in complete Staphyloma the sooner the protrusion is excised the better; the ball is the more likely to remain of a size well fitted for an artificial eye, and the less risk is there of sympathetic disease of the other eye. An interesting case shows the benefit which may result from the operation in removing such sympathetic inflammation already lighted up. We are of Mr. Walton's mind, that in sclerotic staphyloma excision must be practised, and that tapping the eye is not only useless but dangerous.

Conical Cornea is the subject of chapter fifteenth. Mr. Walton's figure is excellent: that in Mr. Dalrymple's work is one of the few failures in that beautiful book. The only means of relief in this disease, and a very uncertain one it is, is the employment of a concave lens behind a pierced diaphragm. Surgical interference is to be eschewed.

Now and then the surgeon has succeeded in removing Opaque Deposits from the Cornea; but the most important point to notice is what our author justly enforces in chapter sixteenth, the astonishing way in which the cornea often cleans, especially in young people, by the efforts of nature alone.

Chapter seventeenth treats of Cataract. A very good account is given of the different kinds of cataract and of their diagnostic marks. These are not always very certain:—

"The following anecdote illustrates the practical bearing of the matter. Some years since, a clergyman, forty years of age, consulted the late Mr. Tyrrell for cataract. Mr. Tyrrell, who never used the knife when he could employ the needle for solution, determined in this instance to extract; his sudden death, however, prevented the operation. The patient then applied to a surgeon, who always extracts when it is admissible, and he operated by solution."

There are in this chapter some very excellent remarks upon the deficiency of the catoptric test, in deciding upon the condition of the lens in aged people.

"The value of the candle test is to be found chiefly in its application to the eye prior to the amber change (from age) in the lens; for then, if amaurosis (only) be present, the three images will be seen clear, and not blurred; if incipient cataract, the images within the eye must be affected according to the degree and seat of the existing opacity. In the aged, it may enable us to compare the degree of opacity with the imperfection of vision; but in them, in consequence of the amber change, the detection of incipient cataract is beyond its power."

In these observations we fully concur. It was but the other day that an aged relative of our own was pronounced to be cataractous of one eye, by an eminent surgeon, who found the vision very dim, and the deep images obscure; but to the surprise of all concerned, vision returned in a few days, the dimness of sight having been sympathetic amaurosis, and the supposed cataract the amber lens of the aged.

An eye is not to be operated on while it retains useful vision; and our author would not operate on one eye while the other retains its usual powers. In this we differ from him, and now and then operate in such cases, with subsequent assurance from the patient of the material benefit he has received.

We much admire Mr. Walton's judicious remarks on the constitutional treatment and regimen proper for cataractous patients before and after the operation. Much greater evil has, in our experience, arisen from debility than from plethora. Good food, cinchona, and ammonia, are often the best antiphlogistic remedies; bleeding, purging, and starvation, the most inflammatory treatment.

We are not quite so sure about his instruments for extraction. The knife we use is longer and more acute than his; and we still prefer to scratch the capsule with the needle bent rectangularly at the point, which we think less likely to catch upon the iris, and more likely to divide the capsule effectually, than the nearly straight curette he employs. Various accidents have happened to us while extracting; but, by introducing the needle with the angle forwards, and withdrawing it in the same way, it has never occurred to us to catch the iris. We are glad that Mr. Walton ignores the cornea scissors and Mr. Scott's sickle, and that he disapproves of chloroform. He uses the excellent contrivance of a very large stiff shade after operating, so as to avoid the necessity of tying down the patient's hands at night.

Mr. Walton, like all good surgeons, looks upon "displacement" as a "do-no-better" in the way of operation for cataract. "Solution" he prefers to effect by operating through the cornea, and urges the necessity of opening the centre only of the capsule, and of leaving the lens as undisturbed as possible in a first operation.

The canula capsule-forceps of late invention comes in for its due meed of praise in the treatment of *capsular cataract*; but we would decidedly include among truly useful ophthalmic instruments one of which our author makes no mention, the beautiful guarded hook of Schlagintweit, with which we have several times operated with complete success. It is small and smooth when closed, seizes the capsule very firmly, and, as it does not expand like forceps, can be worked in a much narrower space. The operation with this instrument, *through the sclerotic*, has prospered very well in our hands, the capsule coming away entire, and no inflammation or amaurosis following.

This chapter concludes with a notice of the operation of "drilling"; and the next gives a very good synopsis of the recorded cases of Intra-ocular Entozoa and Cysts.

Chapter nineteenth treats of Artificial Eyes; chapter twentieth of Malignant Diseases of the Eye; and here, as in the section upon *nævus*, we are presented with a masterly summary of the present state of our knowledge of the pathology of cancer, as introductory to the author's more immediate subject. The different species of ocular cancer are well expounded; and the practical conclusion as to surgical treatment is, that the operation should not be resorted to save in cases of melanotic and of epithelial cancer, in which it has now and then been followed by a radical

cure. Of course, in certain cases, it may be advisable to remove a diseased mass for mere temporary relief.

Chapter twenty-first treats of Artificial Pupil. This chapter, on one of the most interesting subjects in ophthalmic surgery, is, like the rest of the book, well written and complete. It is of course desirable that the new pupil should be as near the centre of the iris as may be; but when, as often happens, this is impossible, our author gives the preference to the *inferior margin* of the iris; and next, to its outer and inferior margin.

As our limits will not permit us to follow Mr. Walton in his excellent account of the various states of the eye admitting of the formation of an artificial pupil, and of the operation generally appropriate to each, we shall just briefly indicate the operations which he describes:—1. Incision with the double-edged knife through the cornea. 2. Incision with extension of the aperture by means of a blunt hook. 3. Division of the iris with Maunoir's or canula scissors, through the cornea. 4. Excision of a portion of the iris, drawn with a hook, or a pair of fine forceps, through an opening in the cornea. 5. Separation of the circumference of the iris by means of a sharp hook,—this last a *pis aller*.

The last chapter briefly explains the surgery of Extirpation of the Eyeball.

In conclusion, we have again to express our very high opinion of a work of which we have been compelled, by want of space, to give a very imperfect abstract, and to recommend it very much to the careful study of all who mean to operate on the eye. Mr. Walton is a safe and judicious guide, and his book is a really scientific professional treatise. The illustrations are excellent, and the index is good.

ON THE LOCAL APPLICATION OF A BENUMBING OR CONGEALING TEMPERATURE, IN INFLAMMATORY, PAINFUL, AND MALIGNANT DISEASES. By JAMES ARNOTT, M.D. 8vo. London: 1852.

THE local application of cold has existed amongst therapeutic agents from time immemorial; but, so far as we are aware, the temperature of melting ice has always been thought sufficiently low to answer every indication, until recently, when Dr. JAMES ARNOTT, thinking that there was no particular virtue in cold of just 32°, has ventured on making applications to the skin in erysipelas, neuralgia, and some other affections, at a temperature below zero of Fahrenheit. Various frigorific mixtures can be used for this purpose; but the one generally employed by Dr. Arnott is a mixture of pounded ice and salt, the preparation and effects of which he describes as follows.

"A bit of ice—the size of a large orange—is put into a canvas bag or a towel, in order that it may be pounded or pulverized, by beating it with a flat iron. The finer this powder is, the better. This is then thoroughly mixed, on a large sheet of paper, with about half the quantity of well-pounded common salt, by means of a paper folder. The mixture is then put into a net of silk-gauze tied to a ring of gutta percha, and is ready for use when beginning to melt. If superficial *anæsthesia* only is intended, this is immediately produced, even before the cutaneous circulation is stopped, or the skin becomes blanched. This stage continued a few minutes will often be sufficient; but I more frequently, when using congelation remedially, continue the process until the adipose matter becomes congealed, and the part becomes hard to some depth as well as white. If this greater effect is produced, there is considerable smarting at the time, and (if not prevented by the application of cold water), for some minutes afterwards, and the skin remains tender for several days. If the process is carried no further than blanching the skin, the smarting is little, and the redness continues only a few hours. After the more efficient application, there is redness and swelling, but evidently not symptomatic of inflammation, as the condition of the part appears to be the very opposite to this. The vessels appear to have lost their tone, and to be insusceptible of inflammation for some time afterwards."

According to the cases related, the benefits resulting from this practice are most striking; erysipelas, neuralgia, and

inflammation of the eyes being permanently removed by one or two applications of the freezing mixture. The following case shows a most heroic use of the remedy.

"A mixture of finely pounded ice and common salt was applied for five minutes over the whole of the bare scalp of a young man, labouring under severe affection of the brain or its membranes. To the usual symptoms of inflammation, including delirium, there were added *risus sardonius*, and a tendency to opisthotonos. He had already been largely bled; but as this and the other usual remedies had produced no amendment, his recovery was despaired of. A few minutes after the removal of the frigorific, he fell into a sound sleep of several hours continuance; and, on his awakening, it was found that the delirium and every other serious symptom had ceased. He speedily and perfectly recovered."

The application of benumbing cold has been applied with success to prevent pain in a few superficial surgical operations. Dr. Arnott has applied it himself in dissecting off a piece of skin in order to form an issue; it has been applied preparatory to introducing setons; and M. Velpeau has also used it in Paris, in the operation of removing the toenail. It is evident, however, that its applicability in operative surgery is very limited; for Dr. Arnott says that, when employed at the bend of the arm before venesection, by pressing a bit of ice dipped in salt on the vein, the incision must be made instantly, otherwise the flow of blood through the vein restores the sensibility of its coats, before the operation is performed.

The following remarks of the author show that the remedy which he advocates requires great care:

"The period of congelation must, of course, to be appropriate, differ in almost every case, and be dependent on the disease and a variety of other circumstances; and the extent to which congelation can be carried with safety is also equally variable."

"In estimating the effect of the application of frigorific mixtures to the animal tissues, it is highly necessary to take into account the condition of the part subjected to them, in respect to its own vascularity, and the vascularity of the neighbouring parts, and as to whether it be in a state of inflammation or not."

"How long the circulation of the blood in the part could be suspended with safety, while, as is usually the case in the remedial employment of congelation, it continues vigorous in other parts of the system, it is difficult to determine; but there can be no hesitation in saying, that not the slightest risk can be incurred by any such short continuance (about five minutes) as is then (in neuralgia) required."

No ill results have followed the application of freezing mixtures in the author's own practice—as we can easily believe; but he relates a case in which a practitioner kept on a not intensely cold application for twenty minutes, and vesication was produced. It will be easily understood that much worse disasters might follow the incautious use of so powerful an agent; and therefore, whilst we recommend its trial, we would advise that it should be employed at first with extreme care.

PRACTICAL AND DESCRIPTIVE ANATOMY OF THE HUMAN BODY. By THOMAS H. LEDWICH, F.R.C.S.I., and EDWARD LEDWICH, F.R.C.S.I., Lecturers on Anatomy in the Original School of Medicine, Dublin. 8vo., pp. 923. Dublin: 1852.

THE words *good* and *bad*, like *little* and *great*, are but relative terms. Spain was once the greatest nation in the world; Spain is now one of the least powerful nations in Europe; yet Spain, as a country, never before was so rich in national resources and in learning as she is at the present hour. She is only a powerless country now, because other countries more powerful have arisen around and before her. She was the *great* country in the days of Ferdinand and Isabella, because all other countries were then less important, and were in her rear.

In the world of literature, this principle has its analogue. A book is good or bad, in proportion as it advances before or lags behind its fellows in the amount of new information which it contains, or in the improvement in literary arrangement which it offers. A book deficient in these respects is, to say the best of it, an useless thing, adding weight to the

library shelf, and giving unrequited trouble to the librarian. The Messrs. LEDWICH, in publishing the volume before us, have either ignored or forgotten these truths; for their book presents no scientific novelties, nor is the information it contains more accurately or more concisely given than is the same information in the works of Wilson or Ellis, Goodsir or Knox. Moreover, the absence of drawings renders it much less useful and readable than most other modern manuals of anatomy. The authors, there can be no doubt, are both excellent anatomists, and excellent anatomical teachers; but they are, as anatomists, in the general body, and not in the van, of their corps.

According to custom, the Messrs. Ledwich commence their labours with a description of the bones—an old custom, by the way, and only commendable in that it makes the cannibal the antipode of the anatomist, in a double sense. They then describe the ligaments; and afterwards, in succession, the muscles, cavities, nerves, arteries, veins, and absorbents.

To illustrate the style of the authors, we shall make two extracts: the one passage is on an anatomical, and the other is on a physiological subject. At page 688 the writers thus describe the anatomical relations of the spinal accessory nerve:—

"Intermediate in size between the pneumogastric and glossopharyngeal, it escapes from the jugular foramen, and dividing into an internal and anastomotic branch which joins the pneumogastric, and an external, which communicating with the glossopharyngeal, ninth and sympathetic, passes downwards and outwards, lying in front of (sometimes behind) the jugular vein, where it is crossed by the occipital artery; then lies on the rectus capitis lateralis, beneath the posterior belly of the digastric, and continuing its course, it pierces the upper third of the sterno-mastoid, communicating with the third and fourth cervical nerves in the posterior superior triangle of the neck; and arriving at the anterior margin of the trapezius, it divides into two branches, one of which ascends to the cervical portion of that muscle, whilst the second descends in its dorsal division. Occasionally the nerve passes beneath the sterno-mastoid, without piercing its fibres, but always sending one or two small filaments to it."

At page 579, the authors offer a physiological description of the pancreas:—

"In structure, the pancreas closely resembles the salivary glands, which have already been fully described; having, like them, its lobules separated by fine fibrous tissue, each containing its follicles of secretion, with its accompanying cell apparatus for the elimination of its peculiar fluid, which is derived from its proper vessels, the splenic, superior mesenteric, and hepatic. An evident analogy likewise exists in the secretions of the pancreatic and salivary glands; but the former contains more solid ingredients, as albumen and casein; has an acid reaction, and no sulpho-cyanate of potassa; while, on the contrary, the saliva possesses the latter, as well as an abundance of saliv and mucus, which is sparingly found in the pancreas. It is extremely difficult to assign a decided use to the pancreatic secretion. It has been said to be of service in diluting the bile, in saponifying the fat globules found in the chyle, and neutralizing the acidity of the gastric juice in the duodenum. The quantity secreted in about twelve hours, by a large dog, amounted to about eight drachms (Tiedemann)."

These extracts will serve to confirm, we think, the general opinion we have given as to the merits of the book.

The descriptions of the anatomy of parts and organs are brief enough, but are often very obscurely worded. The physiological descriptions are commonplace, and may be found in any manual on physiology.

But perhaps it may be urged, that it is impossible for writers on anatomy to advance novelties in their works: it may be said that certain facts have to be stated, that the hands of the anatomist are bound, and that he can only tread on tracks already trodden bare. We do not admit the truth of such a supposition; there is, in our opinion, a wide field for improvement.

The pages of these authors, like those of other anatomists, are loaded with words and expressions so meaningless, so insane, so repulsive, that the eye closes instinctively on looking at them, as though struck with a summer grout.

Will writers on anatomy never shake themselves free from the dust of the dark ages? Not very soon, we fear, if the book now on our desk is to be taken as a sign of advancement. It can hardly be credited, yet it is true, that in this day gentlemen, well acquainted with the whole mechanism of the human body, have spent their precious time, and spoiled their paper, in repeating such terms as Hippocampus Major, Valley of Haller, Valve of Vieussens, Iter a tertio ad quartum Ventriculum, Septum Lucidum, and other verbal abominations.

PERISCOPIC REVIEW.

SURGERY.

ACUTE HYPERTROPHY OF BOTH MAMMÆ: EXPLORATORY PUNCTURES: DEATH: DISEASE OF OVARIES, BROAD LIGAMENTS, & UTERUS.

THE above title is a summary of a very interesting case, instructively described and commented upon in No. 1 of the *Glasgow Medical Journal* (April 1853), by Dr. J. A. LAWRIE, Professor of Surgery in the University of Glasgow. Mammary enlargement is a well known consequence of sexual excitement, or of ovarian disease; and in the present case, hypertrophy of the mammae probably proceeded from the ovarian disease which was found on dissection. This disease may have been either the cause or the result of sexual excitement, or both. The immediate cause of death was undoubtedly toxæmia; and the symptoms place the case along with those of what are termed surgical fever; cases which the researches of recent good observers incline us to believe, to be either identical with, or similar in its nature to, puerperal fever and erysipelas. The differences which exist between them we regard as accidental, and not as essential. We quote Dr. Lawrie's remarkable case in his own words, and with hardly any omission; so that our readers may for themselves judge of its character.

CASE. Mary D., aged 30, called upon me about the 9th April 1852, complaining of general pyrexia. She made no complaint of her mammae; but two days afterwards, she said they were painful. I found them very slightly enlarged, painful to the touch, the areola I thought darker, and the papillæ more prominent than natural, the integument otherwise normal. Suspecting sexual uterine excitement, I questioned her very closely. The girl, being from the Highlands, and speaking English imperfectly, did not give very satisfactory or intelligent answers; but the impression left on my mind was, that she might be, and probably was in a very early stage of pregnancy. I accordingly prescribed some gentle diaphoretic medicine, and waited the result. The only cause that she could assign for the enlargement of her breasts, was sudden transitions from heat to cold, from her employment as a cook.

As the breasts continued to increase rapidly, I sent her to the Infirmary on the 19th April. She proved a very discontented patient, and twice left the hospital without permission, so that the treatment employed had not very fair play. From whatever cause, none of the means prescribed had the slightest beneficial effect. They consisted, in the early stage, locally of frictions and fomentations, followed by cold and gentle pressure, leeches, and acupuncture; internally, mercury to the extent of gentle salivation, and iodine freely.

On her admission into hospital, 19th April, the breasts are described as enlarged to double their natural size, firm, elastic, resistant to the feel, but very irritating and inconvenient from their weight and size. The integuments were not discoloured, and slightly painful. She left the house on the 28th, and returned on May 7th. The mammae are then reported "to have increased very much in size, to be affected with acute stinging pain, and to have assumed a bluish colour". These symptoms continued to increase, the suffering became very great, and the colour of both breasts was a deep purple before her death. They were firmly bound to the chest; and, from their tension, caused not only pain, but considerable difficulty of breathing. The lobulated form of the glands was very distinctly felt. That their vascularity was great, was shown by the jets of blood which flowed from the puncture of a common-sized grooved needle. In a few minutes, I collected six or eight ounces, and, to all appearance, I could have bled her as freely from this small aperture, as if I had opened a vein in her arm. About

the 10th or 12th of May, her general health began to give way rapidly: typhoid symptoms set in, she became partially hemiplegic, and her tongue was much drawn to the left side. She died on the 17th. I showed her twice to my colleagues in consultation; none of them had ever seen a similar case. Surgical interference was considered quite inadmissible, and no means beyond those already employed were suggested.

Autopsy. I entrusted the *post mortem* examination to my friend, Dr. Wm. Aitken, Demonstrator of Anatomy to the University, and Pathologist to the Infirmary, who has most kindly sent me the following report:—

"*Mamma.* A cast having been taken of the external form of the breasts immediately after death, the mammary glands were removed from the body for inspection and preservation. The right gland was larger than the left, but each preserved the characteristic lobulated form and arrangement of the gland substance. Along with the skin and a small portion of pectoral muscle which accompanied each gland, they weighed six pounds fourteen ounces; and it was observed that the skin covering them was less tense than before death, probably from the gravitation of the blood towards the dorsal regions of the body. The right, and larger gland of the two, when freed of all its accessory parts and hardened in spirit, so as to remove a considerable portion of water from its substance, weighed two pounds two ounces. The hypertrophy appeared to depend upon the following conditions of the gland substance, and its accessory parts:—1. The acini were distended to about twice their size, compared with those of a mamma which had never secreted milk. This distension appeared to be due, partly to a granular exudation, and partly to a very large amount of epithelial cells, mingled in some places with globules of oil. The ducts of the acini were also in some places irregularly distended with this epithelial secretion. 2. On examining a section of the gland, harder portions could be observed, which, when isolated from the rest of the gland, varied in size from a millet seed to a pea, or a bean; and microscopic observation showed that these harder portions were the seat of an abundant exudation and secretion. 3. Immediately below the skin, a layer of exudation filled up the space between the lobules, making the surface of the gland assume a rounded aspect. This exudation was of a granular appearance, similar to fibrine in its first stage of organization; and it was found abundantly exuded into the interspaces between the tubes and ultimate lobules of the gland, apparently taking the place of the fat usually found there, and which had probably disappeared by absorption, the result of pressure. In each axilla the lymphatic glands were much enlarged, and infiltrated with a granular exudation.

"*Liver.* Circumscribed deposits were irregularly and sparsely scattered throughout the whole substance of the liver, projecting in some places from its surface. They varied in size from a pea to a plum, presented a granular appearance microscopically, and no liver cells could be distinguished among the substance of these deposits; and while they were perfectly circumscribed by the capsule of Glisson, the secreting substance of the gland was condensed round their periphery.

"*Uterus and Ovaries.* The ovaries and broad ligaments of the uterus were morbidly adherent to the walls of the pelvis, and appeared to be infiltrated with a serous exudation. The ovaries, on removal (and more especially the right one), were found to be in a state of inflammatory softening, and much enlarged. The Fallopian tubes also were unequally distended, especially near their fimbriae, which adhered firmly to the ovaries. The softening was so great, that the substance of the right ovary was easily broken down under the finger, and no appearance of extravasated blood, or of corpora lutea, could be detected in either. The uterus was somewhat larger than one whose cavity had never been distended by conception. Its neck was more especially elongated, and did not terminate in an anterior and posterior lip separated by a transverse slit, as in the normal uterus. A pointed sugar-loaf-like apex projected into the vagina, through which an opening with an irregular border led into the cavity of the uterus; but so contracted, that a probe about two lines in diameter was all that could be passed through it. The whole aspect of this part of the uterus perfectly resembled what is described as the result of ulceration and cicatrization of the neck and mouth of the uterus. The substance of the organ, more especially near its fundus, enclosed condensed white portions, like the commencement of fibrous tumours in its substance."

REMARKS. 1. This case was to me one of very great interest. I had an opportunity of watching it from its commencement to its close, and had the great mortification to see a case, which I at first was inclined to consider "natural", or if disease, trivial,

steadily go on from bad to worse, resist every remedy employed, and prove fatal in thirty-eight or forty days.

II. No one who saw the patient had ever seen a disease at all resembling it. I believe that any form of hypertrophy of the mamma is rare, but this peculiar form especially so; indeed, I am not aware of any recorded case exactly similar to it. Hypertrophy of the mamma has been divided into the false and the true. In the false, the gland is either not increased in size, or is atrophied, while the reticular adipose and other tissues are inordinately augmented. This form is chronic, and is usually met with in females from forty to sixty years of age. The true has been variously subdivided into—that occurring at puberty; in the adult; the acute; and the chronic. The first is very often vicarious of menstruation. Of its chronic form, examples are given by Sir A. Cooper, under the name of "large and pendulous breast"; and by Mr. Hey, of Leeds. Of the acute, terminating fatally, an instance is given in the *American Journal of Medical Science* for August 1834, p. 374. That case resembles the one now detailed in this, that the ovaries were enlarged, and apparently diseased, and that the uterus gave evidence of recent acute inflammation; but it differs from it essentially in this, that the cause of death was superficial sphacelation of the left breast, the result of a recent injury. In the fourth volume of the *British and Foreign Medical Review*, is a notice of a paper by Dr. Fingerhuth, of Esch, on hypertrophy of the mammary gland. This paper (I have not seen the original) seems to contain valuable information on the history, symptoms, and pathology of the disease. So far as I can gather, however, it contains no case similar to the present; and although Mr. Birkett, in his treatise on *Diseases of the Breast*, quotes Dr. Fingerhuth's cases, as examples of "true hypertrophy in the adult", it is expressly stated in the *Review*, that "the disease always makes its appearance at the period of puberty, and is contemporary with the development of the mammae; either the patient has never menstruated, or the catamenia are scanty, and soon disappear". All the cases quoted, are at or about the age of puberty. Dr. Rasi, an Italian physician, gives a case in which hypertrophy seems to have taken the place of lactation in a woman aged 10. The disease was resolved, but recurred in several successive confinements, proving fatal in the sixth, on the fourteenth day.

The case now detailed seems to be unique in the following respects:—It occurred in a woman, aged 30, without any ascertained cause; it affected both mammae; it ran a rapidly acute course, resisting all remedies, and terminating fatally in forty days; and it presented appearances in the ovaries and liver, not hitherto observed in any case of hypertrophy of the mammae.

III. The dilated acini seem to have contained an unusual excess of epithelial cells, and granular exudation, especially the former. The large amount of exudation under the skin, and between the tubes and ultimate lobules of the gland, and the absence of fat, appear also to be uncommon; at least, they differ essentially from Dr. Fingerhuth's observations, in which it is stated, "the cellular tissue is loose, the cells larger than natural, and containing a remarkable quantity of fat".

IV. The state of the liver and ovaries is certainly not the least interesting point in this remarkable case. Dr. Aitken, in some valuable notes which he kindly sent me, considers the epithelial deposits in the mammary acini as "degenerate". I am rather disposed to consider them as analogous to, or possibly the second stage towards the formation of, those circumscribed abscesses which are so frequent a cause of death in surgical and obstetrical practice. I am one of those who deny that these secondary abscesses are always connected with phlebitis, and uniformly depend on purulent infection. I think I have met with them where there was no wound of the skin. Certainly, I have found them connected with wounds of all sizes, and in all states or stages. In the case before us, the substance of the mammae was penetrated with an exploring needle three times. Were these deposits in the liver, and softening of the ovaries, an instance of that rare form of secondary disease (or surgical fever, as some style it), in which there is no lesion of the surface, or were they examples of its common form, and caused by the exploratory punctures? That they were one or other of these appears to me but too probable.

V. The causation of the disease is obscure. The state of the uterus rather confirms my suspicions that sexual excitement was its starting point. But why so rare a consequence from so common an antecedent?

CASE OF CIRROID ANEURISM.

In No. I. of the *Glasgow Medical Journal* (April 1853), Dr. J. A. LAWRIE completes the history of a case of cirroid aneurism,

which he contributed to the 31st vol. of the *Medical Gazette*. The patient first presented himself in 1841; was then cured by ligature of the brachial artery in the lower third of the arm; and in 1852, eleven years afterwards, dangerous hæmorrhage having occurred, he entered the Royal Infirmary of Glasgow, where Dr. Lawrie, after consultation with his colleagues, tied the brachial artery at the bend of the arm, but had at last to perform amputation at the lower part of the forearm.

The wrist and hand were dissected by Dr. Aitken; and the following is his report:—

"Two large sloughs existed in the palm of the hand, having an external opening to each about the size of a shilling, from which the injection freely flowed, when propelled either from the trunk of an artery or a vein. On dissecting the hand, the blood-vessels presented a peculiar convoluted appearance, more marked at two situations; namely, in front of the pronator quadratus muscle, immediately above the position of the annular ligament of the wrist, the remains of which existed in the shape of a fibrous cord, and towards the ball of the thumb on the external and lateral aspect of the wrist. The veins were very much enlarged in calibre, and irregularly dilated, communicating, by long tortuous vessels round the wrist, with the arterial plexus of vessels, chiefly from the radial and interosseous arteries.

"The arterial tubes presented all the characters peculiar to that condition of the vessels known as cirroid aneurism; namely, irregular widening of the calibre; tortuosity of route, presenting an appearance, when the binding tissue was separated from them, resembling small coils of intestines attached to a mesentery; protuberances and elevations along their course; irregular thickening of the coats at some parts, and thinning at others; the walls of the larger arteries were soft and flabby, and in the flesh condition; the inner and middle coats (where they could be seen) were of a pale colour, and did not exhibit that soft yellow hue, so characteristic of healthy arterial tissue. By a careful comparative examination with the microscope, the more dilated portions presented the following characters:—

"I. Their walls were so thin, that they approached the condition of veins.

"II. A very small amount of the characteristic yellow elastic tissue could be distinguished, and the elongated pale contractile cells peculiar to the middle coat of the arteries, and to involuntary muscle, could not be seen.

"III. The thickened portions of the arteries seemed to depend upon an increase in the amount, and subsequent condensation of the binding tissue enveloping their walls, while the thinning of the coats seemed to be partly the result of morbid deficiency of the arterial tissue, and partly of pressure by contiguous distended vessels.

"On making a section through the ball of the thumb and palm of the hand, the tissue was condensed in its general aspect, but very porous from numerous openings, varying in size from a point visible to the naked eye, to the size of a small bean. It presented all the characters of very vascular erectile tissue; and all the openings were observed to give out fluid simultaneously with the slightest pressure upon the large vascular swellings situated in front of the arm. The sloughs on the palm of the hand had numerous openings into them, and one very large opening, partly filled by coagula, communicated with the large tortuous caverns of the blood-vessels in front of the arm."

Dr. Lawrie's remarks are worthy of attention. He says:—

"This is unquestionably a rare disease. So far as I know, few, if any, examples of it have been recorded since I gave an account of this case in 1843. I then alluded to cases related by Breschet, Cloquet, and Dupuytren, and to two in the temporal artery which occurred in the Glasgow Infirmary.* I divided the diseases into two forms: first, when it occurs uncomplicated; and second, in combination with erectile tissue. Of the former, Breschet's, Cloquet's, and the Glasgow cases are examples; to the latter belong Dupuytren's case, and that now detailed. The pathology, prognosis, and treatment of the two forms are different. The first consists of dilatation, and thinning of the arterial coats, with tortuosity of the vessel at certain points of its course, so great as to form a tumour composed solely of arterial coils. If deeply seated, as in Breschet's cases, it may not be discovered during the patient's life, causing little annoyance, and rarely giving rise to hæmorrhage. Surgical interference is not essential, and when demanded, consists of ligature of the dilated vessel, at the point where the coiled tumour commences. I endeavoured to show that there is no risk in tying the dilated

* Glasgow Medical Journal, vol. 4, p. 82.

artery, and that ligature of a distant healthy arterial trunk is not justifiable; as, for example, ligature of the carotid in cirroid aneurism of the temporal artery. In the second form, we have the same pathological condition of the arterial trunks, with the addition of erectile tissue. The prognosis is more serious, because dangerous hæmorrhage is a common consequence of a wound or ulcer, and because it is much less amenable to treatment. The treatment is more complicated; ligature of the diseased or sound artery is not sufficient, and measures must at the same time be employed for the obliteration or removal of the erectile tissue.

"These opinions are fully borne out by the sequel of M'Lellan's case, as now detailed. Ligature of the arterial trunks, in 1842, arrested, but did not cure the disease; and at the end of eleven years, an injury caused ulceration, ending in hæmorrhage to a most dangerous extent. On his admission into hospital, in March 1852, I endeavoured to carry these views into practical operation, but unsuccessfully. The cause of failure was probably the great progress which the erectile disease in the hand had made, the large size of the ulcerated openings, and the consequent enormous hæmorrhage. Be this as it may, all attempts to cure the disease in the hand by cautery and ligature, and to arrest the bleeding by deligation of the arterial trunks, proved abortive. After the hæmorrhage on the 14th March, two modes of procedure were discussed in consultation—ligature of the subclavian, and amputation. Had the hand been less mutilated, the former of these might have been adopted; but I did not think myself justified in incurring so serious a risk, for the doubtful preservation of a comparatively useless limb. One other procedure was not thought of, which, on further consideration, I think ought to have been tried before having recourse to amputation; viz., ligature of the radial and ulnar arteries as near to the wrist as the erectile tissue would have allowed. We overlooked the fact, that in 1842, deligation of the ulnar artery succeeding in arresting the bleeding after that of the brachial had failed. Possibly the same might have happened again; and should a similar case present itself to me, I certainly would tie the arteries leading to the diseased and bleeding tissue, as near to that tissue as possible.

"The further experience of this case shows, that arteries affected with cirroid aneurism, may be tied as safely as a sound vessel, whether the ligature be applied as in the ordinary operation for aneurism, or to the open mouths of vessels after amputation.

"The patient continues well, and has returned to his occupation as steamboat engineer."

UMBILICATED ACNE TUBERCULOSA.

The following observations were made by M. PROGEY at a meeting of the Société du Biologie in Paris, as reported in the *Gazette Médicale* for January 29th.

The subject of these remarks was a young girl, who had on her face eleven prominent convex tubercles, paler than the surrounding skin, and each possessing a central or lateral depression: they varied from the size of a pin's head to that of a pea. One of them, redder and larger than the rest, and formed by the aggregation of several follicles, resembled a wart. They all contained sebaceous matter, which could be squeezed out by pressure. The diseases described under the names of molluscum contagiosum, molluscum pendulum, adermoptosis, follicular elevations, varioliform acne, molluscoid acne, all bore a relation to the affection now described. Previously to the judicious memoir of M. Caillaud, each author believed that he was describing a new or unknown disease. But they agree as to the anatomical situation, the course, duration, and termination. The error arises from their having founded their nomenclature on the external appearances, without taking into account the situation of the swellings.

In describing the disease under the name of follicular elevations, (*élevures folliculaires*), M. Rayer has approached nearest to the truth. He says that acne is a change in the cutaneous follicles, characterized by hypertrophy, or the development of a pustule. But, as the term "varioliform acne" gives rise to the idea of a pustule more resembling that of small-pox than that of simple acne, it should be replaced by the name of *umbilicated acne tuberculosa*.

The diagnosis is easy. Acne sebacea or punctata is not accompanied by elevations of the dermis. Syphilitic tubercles, and the tubercles of lupus, have a special colour, and their limits are not clearly defined. Warts are irregular and more coloured, and prolongations of the epidermis are flaccid, and less dense and more coloured than the skin. Besides, none of these contain

sebaceous matter, the distinguishing mark of umbilicated acne tuberculosa.

The disease terminates either by spontaneous evacuation of the sebaceous matter, or by falling off of the tubercle after strangulation of its base.

The treatment should be confined to the use of alkaline lotions, and to pressure on the tumour with the object of promoting the exit of the contained matter: it is only in exceptional cases that recourse should be had to operation.

REPORTS OF SOCIETIES.

ROYAL MEDICAL SOCIETY OF EDINBURGH.

The ANNUAL DINNER of this Society, now in the hundred and sixteenth year of its existence, took place in the Waterloo Hotel, on Thursday the 10th March. Dr. W. Murray Dobie, Senior President, occupied the chair, and Doyle M. Shaw, Esq., Pres. Ann., officiated as croupier.

In addition to a very large attendance of ordinary members, there were present the Presidents of the Royal Colleges of Physicians and Surgeons, several of the Medical Professors of the University, and other distinguished members of the profession in Edinburgh. The chairman stated that he had received letters from the Very Rev. Principal Lee, the Rev. Geo. Coventry, and other gentlemen, expressing regret at being unable to attend the dinner.

The CHAIRMAN, after the loyal and usual toasts, proposed the toast of the evening—"The Prosperity of the Royal Medical Society"—a toast to which every one present would, he was sure, most heartily and affectionately respond. (Cheers.) The present annual dinner marked an era of no ordinary interest in the annals of the Society. For some years past, it had been gradually rising from the mists which, for a time, surrounded it; and this session it had burst forth with unexpected brilliancy and life. The old hall, which had been so reluctantly parted with, was now deserted, and the Society had reared its head in a splendid edifice, with accommodation in every way suited to the dignity of the institution, and the necessities of its members. A change still more notable had come over its internal life: an influx of intelligent members had taken place almost unprecedented in the history of its most palmy days; papers of the highest excellence had been read at every meeting, and discussed with a spirit and acuteness, of late years quite unusual. (Loud cheers.) Who could doubt that these were the presages of still better times—the dawn of a more glorious day than it had ever yet been the lot of the Society to witness? The dinner of the Society was always looked forward to by its members with pleasing anticipation; their annual meeting was always a peculiarly delightful one. Here the professor and the student, the teacher and the taught, threw aside for awhile their mutual relations, and sat down together at a common board, to spend an evening in conviviality and harmony; differences of age and position were for a time forgotten; the professorial dignity in the one case was merged in fraternal familiarity, and in the other reverential awe gave place to filial affection. (Cheers.) Many who had attained the highest pinnacle of renown—many who now stood on the proudest pedestal of science, confessed with gratitude that the foundation of their fame had been laid by the Medical Society: but for its stimulus, their intellects might have lain dormant; but for its tutoring and discipline their energies might have been expended on vain projects or useless trifles. It was impossible to estimate how many young men had been first imbued, at the meetings of the Society, with that love of science, the strength of which had been so fully proved by their subsequent fame, fortune, and success. The Medical Society had always been regarded as a great feature of the Edinburgh Medical School, and as the most powerful auxiliary which our University possessed. They had gone hand in hand in their mutual endeavour to advance in science. What had been the case in former times would continue to be so in future. The Medical Society would never be dazzled by the specious and arrogant pretensions of some who, in this age of quackery and imposture, offered to its notice principles as unsound as they were dangerous, and theories whose tinsel glitter served only to mask their utter worthlessness. If the Medical Society was to continue its hitherto unsullied and glorious career, it was to those members who had recently been added to its ranks that it must look—by them must it be upheld. As years rolled over the time-honoured head of their noble institution, he trusted that,

at many a future meeting like the present, the toast he now proposed would be hailed with an ardour as fervent, with an enthusiasm as sincere, as he was sure it would now receive. (Enthusiastic cheering.)

The CROUPIER proposed, "Their venerable Alma Mater—the University of Edinburgh and its Professors." Professor Traill responded to the toast.

F. O. B. DE CHAUMONT (Curator of the Library) proposed "The College of Physicians, and its President, Professor Traill." Dr. Traill returned thanks.

A. M. ADAM, Esq., (Honorary Secretary,) proposed "The College of Surgeons and Dr. Combe." In the absence of Dr. Combe, who had been obliged to leave, Professor Syme replied.

Mr. HUTCHINSON (Honorary Secretary) proposed "Prosperity to the Medico-Chirurgical Society of Edinburgh, and its President, Dr. Simpson." To the many honours conferred on Dr. Simpson, a fresh one had recently been added, by his election as a member of the Imperial Academy of Medicine of Paris. Professor Simpson acknowledged the compliment in an eloquent speech.

Mr. SYME proposed the health of Sir James Grant, a gentleman who had rendered to the medical department of the army important services, during an arduous career of sixty years. He was the principal medical officer present at the glorious battle of Waterloo; was one of the only three surviving veterans who were engaged during the whole of the Peninsular campaign; and was also the oldest living member of the Royal Medical Society. (Cheers.)

Sir JAMES GRANT, in replying, said, it was true that his period of active service had been a very long one; that Sir Thomas Brisbane, Lord Gifford, and himself, were the only officers now alive who had served in the Duke of York's campaign; they were, he might say, the alpha and omega of the British army. He joined the Medical Society in 1791; and the benefits he had received during his membership had proved of the greatest use to him. (Cheers.)

Dr. COBBOLD proposed "The Extra Academical School, and Dr. George Wilson." Dr. Wilson replied. Dr. Broadbent proposed "The Royal Infirmary, and Professor Syme"; to which toast that gentleman responded. Dr. Dewar proposed "The Physiological Society of Edinburgh, and its President, Professor Bennett." Dr. Bennett replied. The Croupier then gave, "Mr. G. F. Macfarlan, the Society's Treasurer, and all absent friends." "The health of the Chairman," by Professor Simpson; "Dr. Alexander Struthers, an absent President," by Dr. Matthews Duncan; and various other toasts followed.

(Abridged from *Edinburgh Courant*.)

ASSOCIATION INTELLIGENCE.

BATH AND BRISTOL BRANCH.

The QUARTERLY GENERAL MEETING was held on the 24th March, at the York House, Bath: the President, GEORGE NORMAN, Esq., in the chair.

The following gentlemen were present:—John Barrett, Esq. (Bath); J. S. Bartrum, Esq. (Bath); Charles Bayliffe, Esq. (Chippenham); William Colborne, Esq. (Chippenham); John Colthurst, Esq. (Bristol); James Crang, Esq. (Tisbury); W. Davies, M.D. (Bath); Conway Edwards, Esq. (Bath); Farnham Flower, Esq. (Chilcompton); James Godfrey, Esq. (Bristol); Henry Hensley, Esq. (Bath); Joseph Hinton, Esq. (Blaina Iron Works, Newport); Joseph C. S. Jennings, Esq. (Malmesbury); George King, Esq. (Bath); George King, Esq. (Melksham); Joseph Lawrence, Esq. (Bath); Crosby Leonard, Esq. (Bristol); Frederick Mason, Esq. (Bath); E. S. Mayor, Esq. (Bristol); J. J. Mitchell, Esq. (Bath); G. S. Ogilvie, Esq. (Bristol); George Plimmer, Esq. (Melksham); W. Y. Sheppard, Esq. (Bristol); Charles Smerdon, Esq. (Bristol); John Soden, Esq. (Bath); John Kent Spender, Esq. (Bath); R. N. Stone, Esq. (Bath); J. G. Swayne, M.D. (Bristol); S. H. Swayne, M.D. (Bristol); E. Swete, Esq. (Bristol); James Tunstall, M.D., (Bath); G. T. Vicary, Esq. (Warminster); etc.

MEDICAL REFORM BILL.

The PRESIDENT read a letter from Sir Charles Hastings upon this subject, stating that a deputation from the Association had had a most satisfactory interview with Lord Palmerston; that

he was in hopes that government would adopt and carry the bill which had been drawn up for the Association; that the neighbouring members of Parliament had promised their active support to the measure; and that there was every probability of the present attempt at legislation being successful.

INCOME-TAX.

The PRESIDENT called the attention of the meeting to this subject, with special reference to the petition lying for signature in Bath, which is similar in its prayer to that adopted at Worcester, and published in the Journal. We understand that this petition has been signed by upwards of seventy practitioners of Bath and its vicinity, and is to be presented to the House of Commons by the Bath city members.

INTERNAL STRANGULATION OF THE BOWELS.

Mr. HINTON read a paper on this subject, in which he detailed an illustrative case, and advocated early recourse to operation. He likewise laid on the table an abstract of 123 cases, in which the causes, treatment, and results, were given. [We have received Mr. Hinton's manuscript for publication.]

Dr. DAVIES observed that, in cases of this description, opium was the sheet-anchor: croton oil and tartar emetic only added to the irritation already existing. In many cases, enemata were useful by exciting the intestines below the stricture to throw off the flatus distending them. Depressing remedies were to be avoided, while antispasmodics, especially assafoetida and turpentine injections, were serviceable. Dr. Davies could not quite agree with Mr. Hinton as to the desirableness of an early operation; for, under the most favourable circumstances, the operation was a most fearful alternative. Cases might be mistaken for ileus, which occasionally comes on as suddenly; and we could seldom with any certainty place our finger on the spot where lay the source of danger.

Mr. JOHN BARRETT had some confidence in the early use of tartar emetic, which, by inducing collapse, might tend to relax the restraining cause of stricture, while it did not permanently depress the powers of the patient. The great objection to the operation was the fact, that often cases of the worst appearance got well of themselves, and that sometimes we find cases presenting during life no symptoms that would justify operation, which would have been at once relieved by surgical interference; while, on the other hand, in some of those promising the best result while alive, after death no adequate cause of the symptoms could be discovered.

Mr. LAWRENCE narrated two cases favourable to Mr. Hinton's views, in which, had the abdomen been explored, the lives might probably have been saved; one being a case of obturator hernia; the other, strangulation by a band of adventitious membrane. In a third case, where the symptoms were referable to a small spot, the child recovered speedily when salivation was induced. [These cases we hope to receive for publication.]

Mr. NORMAN observed that the diagnosis was so obscure, that Mr. Hinton's analysis of so large a number of cases was very valuable. In the majority of such cases, the doubt as to the exact or probable cause of the symptoms was so great, that the surgeon would not be justified in operating at once: by this necessary delay, time was lost when it was of most value. Such cases resembled strangulated hernia, where, having failed to reduce the hernia, the operation should at once be resorted to: in this latter case, the incision was small, and so of less moment; whereas, in these cases of obscure internal strangulation, a large incision was required, adding much to the danger of the case, besides the handling the intestines, and shock to the nervous system; so that altogether the surgeon must be careful not to give an encouraging prognosis.

While on the subject, he mentioned the results of an operation, upwards of two years ago, on a young woman, for ovarian tumour, which, on opening the abdomen, could not be removed. The tumour, however, had disappeared; she had perfectly recovered her size and her health; she menstruated regularly; had married, but had not been pregnant. (See *Provincial Journal* for 1851, p. 5.)

Mr. GODFREY, in such cases, had felt, in common with others, the anxiety produced by finding, on dissection, that the case might have been relieved by operation, and detailed the following case. A young man was admitted into the hospital with a simple fracture of the leg. There came on suddenly symptoms depending evidently on internal mischief. On *post mortem examination*, there was found a simple serous cyst, attached by a pedicle to the colon, which had embraced a portion of the gut, and might have been at once relieved by placing the patient in the *decubitus*

* Vide ASSOCIATION JOURNAL for March 25th, p. 263.

position, which, however, from his fractured leg, was not thought of.

Mr. HINTON, in answer to an inquiry, stated that he had not used chloroform, nor had he much hope from it in cases where the obstruction was beyond our reach. He recalled the attention of the meeting to the experience of Mr. B. Phillips, who, in his paper published in the *Medico-Chirurgical Transactions*, had recorded that, in 300 cases of opening the abdominal cavity, only 44 had died. In all operations requiring the abdomen to be opened, the room ought to be of blood-heat, as removing one source of irritation to the peritoneum, by warming the air impinging upon the exposed surface. In cases of this character, he had derived benefit from the use of tartar emetic.

CONGENITAL OCCLUSION OF THE DUODENUM.

Mr. MASON read the history of a case of congenital occlusion of the duodenum in a child which lived eighteen days, and during that time passed an excretion resembling meconium. The preparation was exhibited. [We have received Mr. Mason's manuscript for publication.]

Mr. NORMAN mentioned a case in which the subject had lived for twenty-one days, with imperforate anus. On dissection, it was found that the rectum terminated in the bladder.

Mr. HINTON called attention to a reported case where a child with imperforate anus on whom an operation was refused lived for upwards of one hundred days.

Mr. MASON suggested that the reason why some of these cases could exist so long was, that the system of the patients was supported by the food, when retained for any time, being partially digested and absorbed. Where, on the other hand, the obstruction was high in the intestinal tube, no such absorption could take place. In his case the singularity was, that with such perfect occlusion of the canal, meconium, or a liquid exactly like it, should have passed for so long a time after birth, and when there was no apparent communication with the liver or its ducts.

HOT BATH IN SUSPENDED ANIMATION.

Mr. JENNINGS brought before the meeting the question of the usefulness of the hot bath in cases of suspended animation from drowning, and further illustrated it by two cases of asphyxia from carbonic acid in an ice house. [We have received Mr. Jennings' paper for publication.]

Dr. SWAYNE said that the hot bath as a remedy was most unscientific, as from the increased temperature more air was needed for the decarbonization of the blood, which went on more slowly under a cold temperature, as in hibernating animals.

Dr. TUNSTALL had found that the time for using the hot bath in such cases was immediately after leaving the water; if it were used at a subsequent period it was only adding another shock to the enfeebled system, the whole principle of treatment being to excite vital reaction while respiration was gradually induced.

Mr. JENNINGS had used the galvanic battery only at intervals. As soon as he found the heart's action languishing and respiration becoming more feeble, he reapplied the wires with the most marked result and benefit. The recovery of the case of poisoning by carbonic acid was like that of recovery from extreme drunkenness. In his cases he vainly endeavoured to restore circulation in the limbs, and then with this view only, had used the hot bath, but it was almost immediately fatal.

FRONTAL PRESENTATION.

Dr. SWAYNE read the history of two cases of frontal presentation, and illustrated the subject by diagrams. [We have received this paper for publication.]

In answer to an inquiry by Mr. Edwards, Dr. Swayne stated that in the first case the head was too high up for the forceps, and the treatment was equivalent by his use of one blade as a vectis; and in the second case the natural powers were effecting the desired object.

CEREBRAL AND SPINAL APOPLEXY.

Dr. DAVIES read an unique case of hæmorrhage into the brain and spinal canal, unmarked by the usual physiological symptoms. He exhibited the preparation.

CAN EXCESS OR A DEPRAVED STATE OF THE GASTRIC OR PANCREATIC JUICES DECOLORIZE THE BILE, AND SIMULATE FUNCTIONAL DISEASE OF THE LIVER? By CONWAY EDWARDS, Esq.

[This paper is published at p. 300 of this number.]

EXTENSIVE PROSTATIC DISEASE.

Mr. NORMAN read the following letter, which he had received from a medical friend:—

"My dear Sir,—Perhaps you may have heard, or seen in the papers, that my father is now dead. You attended him about

two years ago, when very ill with retention of urine from diseased prostate; and at that time no instrument could be introduced. My late father called with me on you in Bath, about a year afterwards, when you passed two sounds into the bladder; no calculus could be detected. He has, since that time, gone on constantly drawing his own urine every two hours by night and day; generally with tolerable ease, sometimes with difficulty, and many repeated trials: occasionally he was obliged to send for me to relieve him. He was obliged always to make most violent efforts, as if evacuating the bladder, previous to each introduction of the catheter—sometimes a drop or two of ropy mucous urine exuded from the urethra by the effort, sometimes not—and he then passed the instrument.

"About a year ago he passed a great many small, and some larger, phosphatic calculi of irregular shape. The urine was always more or less ropy and mucous; sometimes bloody, particularly when the instrument was passed in too far, and in every introduction the catheter was passed completely into the passage up to the bows of the instrument. My father took nitro-muriatic acid constantly; and, as a common drink, barley water: these barely kept the urine acid, and sometimes it would be quite alkaline and ammoniacal. Thus he went on, and at the time of his death had introduced the catheter for himself 6,802 times; for he kept a regular account.

"My father had for several years been subject to irregular action of the heart on exertion; and six years ago I was called to attend him in a sudden attack of failure of action, which occurred in the night; his pulse was, when I got over to him, 30. Ever since this he had been unequal to much exertion or walking up hill, and the striving efforts he made every time previous to passing the catheter, and in defecation, much increased the mischief.

"I called and saw him, February 25th, when he complained slightly of pain in his sternum; his pulse was quick, and he looked rather pale, otherwise much the same. This was 4 P.M. At 1 A.M. he relieved his bladder, as usual; and at 2 got up feeling uncomfortable; was putting on some clothes, when he staggered, sunk down by the bedside, and died, at 2,15 A.M., February 26th.

"By his own expressed wish, the body was opened. The following were the appearances, 8½ hours p.m. Body very thin; adipose tissue almost entirely absorbed. The prostate gland was of the size of a large orange; the lateral lobes were the parts enlarged. The consistence was moderately hard, white, with granular and gland-like bodies interspersed. The prostatic portion of the urethra was pervious, and terminated in an echymosed spot, where, no doubt, the point of the catheter touched: hanging over this spot was a body the size of a walnut, attached by a pedicle to the right lobe. The section of it presented the appearance of a salivary gland altered by scrofulous disease. The vesical surface of the prostate was nodulated by the projection of the above gland-like bodies. There were no calculi in the prostate.

"The coats of the bladder were much thickened. The mucous membrane was also thickened, falling into pouch-like folds at its posterior part, in which three calculi, as large as pigeon's eggs, were found, partially adherent to the mucous membrane; and that so firmly, that portions of the membrane came away with the calculi when removed. There were two other calculi unattached to the mucous membrane: these were of small size, as large as a pea, rough, and dark, like mulberry calculi of irregular shape. Those of large size were round in shape, sandy in external consistence, apparently phosphatic; for many days after their removal they smelt putrid and ammoniacal. There were about 3ij of mucous, dark, turbid, and fetid urine in the bladder. The ureters were much dilated. The right enormously so. An inch from the bladder it was cut through, and would admit the index finger readily. The pelvis of the right kidney was very much dilated; the cortical and tubular portions being absorbed and thinned; so that though not materially altered in external appearance it was almost a shell. Its lining membrane was whitened and thickened. The left kidney was dark in colour, containing more blood, but the same process of dilatation had commenced in this also.

"There was about 3j of serum in the pericardium. The heart was flabby and dilated. The aorta very much dilated and studded with patches of atheromatous deposit, particularly near the valves, which, though not diseased in their texture, were loaded round their insertions into the coats of the vessel with the same deposit, which was here cartilaginous to the feel, and must very seriously have interfered with their functions. The left ventricle was large, the walls very thin, the columnæ carneæ much attenuated, hard, and pale. The chordæ tendinæ more

rigid than usual. The right ventricle presented the same appearances, but in a much less degree.

"There was no rupture of any part of the organs; which, from the suddenness of the death, I had expected would have been found. Thinking that this account might be interesting to you, I send it, with apologies for my prolixity."

After thanks had been voted to the authors of the different papers, and to the Chairman, the Meeting broke up.

METROPOLITAN COUNTIES BRANCH.

MEETING TO BE HELD ON 10TH MAY, 1853.

At a meeting of the Council of the Metropolitan Counties Branch of the Provincial Medical and Surgical Association, held in London on Tuesday, April 5th, it was moved by Dr. CORMACK, seconded by Dr. SEMPLE, and carried unanimously:—

"That a General Meeting of the Metropolitan Counties Branch be called by this Council, to be held on Tuesday May 10th, 1853, at four p.m., at 37, Great Queen Street, Lincoln's Inn Fields, for the purpose of considering a proposition to hold three General Meetings annually, besides the Annual Meeting; and also for the transaction of general business."

JOHN FORBES, M.D., *Chairman.*
T. OGIER WARD, M.D., *Hon. Sec.*

EDITOR'S LETTER BOX.

A NEW CHARLATAN.

LETTER FROM B. W. RICHARDSON, ESQ., TO THE EDITOR.

SIR,—During a visit which I lately had the pleasure of paying to the Midland counties, my ears were constantly assailed with accounts of the fame of a wonderful woman who has, in these last months, assumed to herself Esculapian duties, honours, and emoluments, in the little shire of Rutland.

That some of the statements made to me concerning this woman were absurd exaggerations, I have no doubt; but sufficient remains to be told, which, I am sure, strictly true, to astonish your readers and to form a record well worthy of being preserved. Had I, sir, at command, the inimitable pen of our immortal countryman Charles Dickens, I could, I doubt not, out of the materials in my possession, frame a letter, the perusal of which would produce a temporary ague fit in the sides of the gravest of all your grave readers. The heroine of my story, holds in fact, just the same position in the domain of medicine, as the Brother Goose Trap Witness of Mr. Dickens holds in the domain of theology.

A few miles from the town of Stamford there is a little village called Wing. In the neighbouring villages Wing can never have been highly esteemed for its wisdom, as it has long been the custom to speak of its worthy inhabitants as "the Wing fools". This title has its origin in a legend, which says that, in the first days of the Wing history, the primitive natives made a bold but unavailing effort to imprison a cuckoo by encircling it with a staked fence—a preposterous libel of course, and a libel which was once commented on in a manner highly gratifying to the libelled parties. It is said that an aged woman of the place, who possessed in a modest and moderate degree the sybilline virtue, the power to prophesy—a mother Shipton in miniature—on being once touched on the sensitive point of her Wing, replied in memorable words, "that the day would come when more fools should enter Wing, than there ever had been fools in it". This prophecy, which, as a matter of course was only laughed at by profane and uninterested persons, has been a source of untold consolation to the stigmatized villagers, many of whom have believed in its fulfilment with an obstinacy of faith that would have done infinite credit to a Mussulman, and have transmitted the belief to their children, and their children's children.

There is often a truth rolled up in these old prophecies. In the present instance there was a *great* truth undoubtedly, a truth which in these last days has shown itself visibly, and the appearance of which has added another confirmation to the proverb, "Time brings all things to the light".

"The Wing Woman", for such is the popular title of the lady whose fame I relate, was born at the village of Hambleton, near Oakham. Her mother was an amateur professor of the healing art; but with supreme modesty she followed the example of Podalirius and Machaon, and treated wounds and sores only.

No record exists as to the degree of success with which this excellent matron followed her self-imposed labours; but it would seem probable that pecuniarily the avocation was unprofitable, for certain it is, that her daughter was brought up in the lowest state of indigence and ignorance. To the daughter herself, these unfortunate circumstances have in the end proved no hindrances to prosperity. After living many years in great destitution, bodily and mentally, she became connected as nurse, or as some other servant, with the Stamford Infirmary, where the idea of becoming a doctress in her own right in all probability broke upon her. After leaving the Infirmary, she, in the course of time, became located at Wing; and having been warned one night in a dream that it was her mission to cure her fellow creatures of their diseases, she slighted not the inspiration, but commenced after breakfast on the following morning. The poor of the village whom the legitimate professors of medicine in those parts failed to cure, were the first on whom she tried "her prentice hand". Cures, the most marvellous, soon crowned her first, and had she not been a married woman, I should have said her maiden efforts. In true illustration of the Shakespearean philosophy, the circle of her glory enlarged itself; and last summer a second Sir Astley Cooper might have looked with a jealous eye on the crowd of patients who from all quarters sought her advice and assistance. If, indeed, a history of charlatanry were ever to be written (and a most interesting history on that subject might be written by the way), there could not, I believe be found a single instance in which any charlatan had in the short space of eighteen months or two years obtained such a celebrity.

I heard from the mouths of numerous persons who had consulted "the Wing woman" so many accounts concerning her, that I took the trouble to obtain as much information on the subject as was possible. One gentleman, whose word, I am sure is most trustworthy, and who, in a low desponding state of health, was led, in opposition to his better judgment, to consult this medical oracle, has kindly given me an account of his visit, which I shall transcribe in his own words; merely premising, that his statements are quite in accordance with those of other persons well informed on the subject, that his visit took place in the latter part of last summer, and that he derived no benefit whatever from it.

"Having many miles to ride," says my informant, "I left my own home at four o'clock in the morning, and arrived at Wing at six. There were two hundred people there before me, on the same errand, and the place was like a fair: booths were erected in the village for the sale of provisions, and a vehicle ran from the house of the doctress to the Manton Railway Station, a mile and a half distant, to convey back passengers who might be coming as patients. There was a book-keeper at the door of the doctress' house, who was issuing tickets of admission in order to avoid confusion. On applying at the house I found that ninety-seven tickets had been issued already, and that sixty-eight were remaining from the previous day. By paying an extra fee I got the ninety-eighth ticket; but it was seven o'clock in the evening before I could gain admission. The reports I heard in the meantime were of the most curious description. The doctors, I was told, were all fiercely enraged against 'the Wing woman, because she spoiled their trade,' and one worthy Esculapian, who lives not a hundred miles from Oakham, was accused of having wickedly misdirected, and turned ten miles out of their way, a van of sufferers who had inquired of him if they were on the right road to Wing? I was also told of a man who, in conveying to his master a bottle of the doctress' health-giving potion, tasted of it by the way, and found it to give him so much of inward comfort that he partook of the whole, and suffered for several hours afterwards from palsy of the lower limbs, difficult articulation, and obscuration of the senses.

"In conversing with the numerous persons who were there to consult this famous woman, I was surprised to hear from what great distances many had come. There were people from various parts of Northamptonshire, Leicestershire, Nottinghamshire, Lincolnshire, and even out of Surrey. I heard, also, many particulars about the woman herself; was assured on all sides, that she could neither read nor write; that she claimed inspiration; and that she fanned the flame of inspiration by absorbing the pages of old Buchan, which were read to her regularly. I ascertained, moreover, to my great joy of course, that her fees were small, and that, like many practitioners really in the profession, she commenced by practising *gratis*. When her fame widened, however, she begun to take small fees, one, two, three, and four shillings per patient, according to circumstances. She has thus been enabled to have her house enlarged, and to take a run to the sea-side occasionally.

"My admission to the presence of the doctress took place, as I before said, at 7 p.m. In a room on the ground floor of her house her medicines were preparing. Herbs and other things were boiled in a copper, the decoction was then strained through a wicker basket, and transferred to tubs, in which it was fermented with yeast. When ready for use it was conveyed up stairs in wooden pails. The sight of this medicine making was rendered as imposing as possible. On ascending the stairs I was ushered into the presence of the doctress. She received me with great gravity. She was stained all over with medicines, and she and all her friends were dirty beyond description. Her nails were especially filthy. I should take her to be about 30 years of age. She did not like me to describe any symptom, but tried to say what I felt without assistance from me. She struck me as being a shrewd observant woman; and one particularly cautious in what she said. She told me that I should have come to her sooner, and that the liver was diseased. She ordered me to be careful in diet, and so on. Surrounding her were twenty jars containing her various remedies, and these she dispensed by means of a ladle into large bottles. The medicines were of two kinds; the one warm and stimulating, the other containing quinine in considerable quantities. She gave me quinine. In one corner of the room I observed a very filthy old woman rolling pills, with a most disgusting pair of hands; but since my visit a London patient has presented them with a silver pill machine, so that the pills are probably less dirty now—days, if they are not dirt altogether. I left the house greatly disgusted, and wondering how I could ever have allowed myself to be so imposed upon."

I have thus, Mr. Editor, given you a narration of one of the most singular kinds of quackery which has ever flourished, even in this age of quackery. Some of your readers may be inclined to opine that I had done better to let the subject alone—to let it die out of itself, without record. With all deference, I think otherwise; believing that in the history of all such impositions as the one just related, a great lesson is embodied. The success of the "Wing Woman" offers another proof of the gullibility of human nature; and affords reason why other medical frauds, practised by persons much better educated, and far more guilty in point of morality than this miserable, self-deceived woman at Wing, are so successful, for brief periods of time, in the opposition they offer to the progress of true and scientific medicine. In another place, I once endeavoured to show that one great cause of the success of quackery lies in the fact that the science of medicine has advanced so far, and the information of medical men has become so great, that the general public are lost in attempting to follow the scientific physician; but that, being at the same time anxious not to feel ignorant in a matter that so greatly concerns themselves—the cure of disease—they are ready to turn their attention to any medical system which they think they can comprehend, however absurd, or however dangerous, that system may be. I regret that further thought on these matters only confirms me in this opinion; and I imagine that no better proof of its correctness could be offered than the history of the "Wing woman".

Ignorance, Humbug, Impudence, potent three! what wonderful tricks can be played by your agency on simple, marvel-loving, bluff John Bull! Louis Napoleon, standing on the opposite coast, and turning a tenpenny telescope in the direction of Threadneedle Street, makes John open his eyes, gird up his loins, and declare his determination to resist the invader to the death, though he should have all the soldiers of the continent at the call of his trumpet. But there rise up incessantly, under the very nose of John, a hundred arch enemies, who, with the three weapons named above, play with him as with a shuttlecock, and obtain costs for their exertions. Now, the health of John is ever a weak point with him, and hence the quack is at all times ready to offer him battle, and at all times conquers. Unfortunate, credulous John! yesterday, to be cured of a hoarseness, he stared, for three-quarters of an hour, with the most ludicrous expression of countenance, at the slim paws of a Mesmerist; to-day, for a depression of spirits, he is induced to swallow one-millionth part of the trillionth of a grain of natron muriaticum, forgetting altogether that he took two drams of the same remedy with his last potato; tomorrow he will suffer from bile, and, Sampson like, will deliver over his locks, and the delicate balance of his life, to the modern Delilah, the "Wing woman".

With many apologies for this long intrusion on your space,

I am, etc.,

BENJAMIN W. RICHARDSON.

Mortlake, April 4th, 1853.

INDISCRIMINATE HOSPITAL RELIEF.

LETTER TO THE EDITOR.

SIR,—I was very much pleased with Dr. Davies's letter, for I assure you that the Bath United Hospital will speedily ruin us all. All sorts and conditions of people resort thither for advice without question. I have often wished to get a poor patient admitted into the house, but this cannot be done without a ticket from a subscriber; and many of these tickets are given away in *blank* to any person who calls at a subscriber's door, while we practitioners cannot send in a real object of charity. Yet out-patients have merely to take their seats without question; and on a market-day you may see the gigs of the farmers of the district waiting in the next street, while their owners are getting their physic at the hospital. In fact it is only necessary to ask and to have; and the ticket, when given, merely certifies that the person applying is a resident in Bath. The farmers do not want to go in, so no ticket is needed. If you saw the numbers of well-dressed people who go there, you would be surprised. I do not blame them: everything is quite free, and no questions are asked; indeed, with the hospitals and dispensaries, a number equal to half our population are annually the recipients of gratuitous medicine and advice. How can we, who have to support appearances and struggle with the world, live, if our physicians and surgeons attached to these places doctor all who come for nothing? I cannot but see that you are doing a great deal of good by exposing these abuses: and I wish you success. The profession here are all with you,—at least we who live by our profession.

I am, etc.,

A YOUNG SURGEON.

Bath, April 2nd, 1853.

INCOME TAX:—LANCASHIRE AND CHESHIRE BRANCH.

LETTER FROM JOHN HATTON, ESQ., HONORARY SECRETARY FOR MANCHESTER, TO THE EDITOR.

SIR,—Under ordinary circumstances, I should take no notice of anonymous communications; but "a Liverpool member" has brought my name forward in the *JOURNAL* of yesterday, in a manner that certainly requires explanation.

"A Liverpool member" cannot be aware of the correspondence which has taken place between Mr. Jones and myself upon the subject, or he would have known that I was not only willing to call a meeting of our Branch, "to take into consideration, and petition against the Income-tax", if I received a requisition, but was desirous of doing so *on my own responsibility*, if Mr. Jones could hold out any hope of procuring even a moderate attendance of members.

Your correspondent is little aware of the difficulty of bringing together even a *few* associates upon any special occasion, or he would not jump at the conclusion, that "this worthy functionary" refused to call a meeting when required; and if he had taken the trouble to peruse the laws, instead of finding fault, he would have seen that Rule 9 orders "That a special meeting of this Branch may be called at any time during the year, on request of ten members addressed to the General Secretary".

I am, etc.,

JOHN HATTON, Hon. Sec.

Oxford Street, Manchester, April 2nd, 1853.

[The Law seems ambiguous. Is the calling of the meeting optional? The word "may" indicates that the "General Secretary" has the power of calling a meeting upon receipt of a requisition signed by ten members; but it does not express anything more. "General Secretary" is a designation which specially belongs to the General Secretary of the PARENT ASSOCIATION: but perhaps in this case the term refers to the chief Secretary of the Branch.

As regards the not calling of a meeting of the Lancashire and Cheshire Branch, it is very clear that, in the circumstances, the course adopted was that which was supposed to be, and which we believe was, most in accordance with the general wish of the members. Throughout the limits of the Branch, petitions have been extensively signed against the present method of assessing the Income-tax: so that without a meeting the great object in view has been accomplished.—EDITOR.]

NEWS AND TOPICS OF THE DAY.

LORD LYTTLETON'S VACCINATION BILL.

[House of Lords, April 4.]

On the motion of Lord LYTTLETON, the Vaccination Bill was read a second time.

Earl GRANVILLE said, that as the provisions were stringent, he must reserve to the Government the right to consider the details at a future stage, and to introduce amendments.

The Earl of ELLENBOROUGH observed that a fine was inflicted for neglect in vaccinating children; but the bill provided no facilities for the people doing so, and he knew, from his own experience, that such facilities could be afforded with little trouble.

Lord LYTTLETON expressed his willingness to adopt any amendments their lordships might suggest.

The bill was ordered to be committed on Monday the 11th instant.

[From the above it appears, that when we penned our remarks upon this rash and ill-digested measure, it had been read a first and not a second time.]

DEATH FROM FLOODING AFTER DELIVERY, THROUGH THE IGNORANCE OF THE MIDWIFE.

An inquest was held on the body of Mary Squires, aged 41 years, at Wiveliscombe, Somerset, before William W. Munceton, Esq., deputy coroner, on the 17th March. Elizabeth Besley stated, that the deceased was delivered of her seventh child on the 10th March, after being in labour about ten hours. When the midwife, Sarah Gibbs, had separated the child, she attempted the extraction of the placenta, by pulling at the cord. In a short time a portion of the placenta came away; the patient was then undressed and put to bed, when she became sick and faint; there was a slight *flooding*, but *not more than usual*; she continued fainting, and Mr. Edwards, a surgeon, was sent for.

Mr. Henry Leopold Nazer stated that he attended deceased for Mr. Edwards; he found her in bed recently delivered. Sarah Gibbs showed him the part of the afterbirth which she had removed; it was about a third part of the placenta. He examined deceased, and found a profuse flooding going on, which had rendered her faint. He removed the rest of the afterbirth as quickly as he could; he found it high up in the uterus, and partially, but not strongly attached: the flooding ceased on its removal. Finding her sinking, he gave her stimulants, but in the act of swallowing them, she died: he considered that she died from flooding, by a retention of a portion of the afterbirth.

The coroner, in summing up, observed that there could not be any doubt that the poor woman lost her life through the ignorance of the midwife; and he was sorry to say, that too many such cases occurred in this country annually. He thought it was high time that the legislature should interfere, and prevent these ignorant midwives and others from practising. He understood, from good authority, that in many unions the guardians employed them to attend the pauper women instead of qualified medical men—a practice fraught with great danger, and which could not be too highly deprecated.

The Jury returned a verdict in accordance with the medical testimony, and added the following rider—

"We consider that midwives are in general very ignorant of the duties required of them; and that the legislature ought to pass a law to prevent them, as well as other persons, from practising midwifery, without first having undergone an examination before a competent Board of Examiners. And we deprecate the practice of Boards of Guardians employing such unqualified persons to attend for poor women during their confinements, a practice which not only leads to loss of life, but thereby frustrates the economical object of those who hold the purse-strings of the rate-payers."

GLASGOW MEDICO-CHIRURGICAL SOCIETY. The first meeting of the session took place on Tuesday, the 18th March, at 8 p.m.; Dr. Andrew Buchanan, President, in the chair. The Treasurer read a statement of the accounts for the past year. The following gentlemen were then elected office-bearers for the ensuing year:—Dr. Andrew Buchanan, President; Dr. Pagan, Dr. Ritchie, Vice-Presidents; Dr. James Adams, Dr. A. Mackie, Dr. P. Stewart, Dr. E. Watson, Dr. Kirk, Dr. Corbett, Council; William Lyon, Esq., Dr. Thomas Watson, Secretaries; Dr. John Coats, Treasurer.

GLASGOW MEDICAL SOCIETY. At the last annual meeting, the following gentlemen were elected office-bearers:—Dr. James Wilson, President; Dr. James Adams and William Lyon, Esq., Vice-Presidents; Dr. George Robertson, Treasurer; James Fraser, Esq., Secretary.

APOTHECARIES' HALL. PASS-LIST. The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, March 31st, 1853:—

Samuel Lob Martin, Bawtry, Yorkshire; David Conway Evans, London; Thomas Tomlinson, Maldon, Essex; Joseph Barker, Dunham; Henry William Alexander Coleman, London; Richard Thomason Hobner, Hereford; Augustine Batt, Bampton, Oxon; William Brown Pepler, Tinehead, Wilts; Richard Henry Thomas, Ibstock, Leicestershire; Alfred James Dale, Bransby Roberts, William James Shone, London.

MUNIFICENT BEQUEST TO THE CITY OF LONDON MEDICAL CHARITIES. A munificent bequest has just been distributed among the City charities by the trustees of the will of Miss Hardwick, late of Chesterfield, in Derbyshire. This lady's father was, in early life, a surgeon in the mercantile navy, and, for some years before his decease, carried on business in Bishopsgate Street as a wholesale chemist. Miss Hardwick, his only daughter, at his death, withdrew herself entirely from the world, and lived an eccentric life in a small cottage, where her property was permitted to accumulate, as she did not expend upon her establishment a hundred a-year. She died about a year ago, in the mayoralty of Alderman Hunter, leaving the bulk of her property to the Lord Mayor of London, and the Chamberlain for the time being, to act with her executor, Joseph Shipton, Esq., an eminent solicitor at Chesterfield, as trustees, to be distributed among such of the charities of the City of London as they might, in their discretion, select for the purpose. The executor immediately placed at the disposal of the trustees the sum of £18,000, the apparent amount of the residue, after the satisfaction of trifling debts and legacies left by the testator, and the following is a list of the medical charities:—Hospital for Diseases of the Chest, £550; St. Bartholomew's Hospital, £1,100; ditto, Samaritan Fund, £300; ditto, ditto, Maternity Charity, £220; Royal Maternity Charity, £330; City Truss Society, £330; Royal General Dispensary, £330; Western City Dispensary, £220; City Dispensary, Queen Street, £330; Hospital for Diseases of the Skin, £550; Farringdon General Dispensary, £330; Metropolitan Free Hospital, £550; Metropolitan Dispensary, £330; London Ophthalmic Hospital, £550.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XV.

LONDON: FRIDAY EVENING, APRIL 15, 1853.

NEW SERIES.

THE WING WOMAN. Mr. Richardson's letter, and the leading article on the Success of Medical Impostors, have been reprinted by request in the form of a small pamphlet, which may be had, postage free, for 4d., sent in stamps to the publisher of the Journal. The proceeds of the sale will be given to the Medical Benevolent Fund of the Provincial Medical and Surgical Association.

HOSPITAL ABUSES. May we request the Surgeon who forwarded to us five or six days ago a communication on this subject, to favour us (in confidence) with his name and address? We expect every correspondent to communicate his name, not necessarily for publication, but for our own security against error.

COMPULSORY VACCINATION NOT NECESSARILY EFFICIENT VACCINATION.

IN our remarks upon Lord LYTTLTON'S Vaccination Bill in our number for March 25th, we said that the profession would do well to petition Parliament to reject the measure. We argued against the bill, because on the very face of it were stamped crudity, impolicy, and injustice. We admitted that enlightened legislation upon the subject of small-pox and vaccination was required; but we at the same time affirmed that nothing could be more hurtful to the interests of the profession and of society at large, than the over-hasty and random legislation at present attempted by a nobleman, of the philanthropy of whose intentions no one can entertain any doubt. Three weeks have elapsed since we expressed these sentiments. During that period we have had opportunities of conversing and corresponding upon the subject with many persons who are practically acquainted with the present system of vaccination; and we find that the only exception taken to our former article has been, that it did not urge with sufficient vehemence an uncompromising opposition to Lord Lyttelton's bill. If our protest were deficient in earnestness, the reader who takes the trouble to re-peruse our remarks, will perceive that there was at least no want of distinctness in the verdict which we pronounced against the measure. However, we can remove all misapprehension by now stating that our objections to it are as strong as those entertained by any of our correspondents, or as can be entertained by any one—that, in fact, we consider the bill to be unsound in its principle, unworkable in its machinery, and incapable of diminishing by one iota the spread of small-pox.

The bill is unsound in principle; because it seeks to enforce by legal compulsion that which it ought to offer as a boon—that, too, which, if kindly tendered, and accompanied with a truthful warrant of efficiency, would, we are inclined to think, be generally received as a great blessing. Should exceptional cases, in which ignorance resists the boon, still be found, it may then be right to think of a compulsory enactment; but till an efficient system of voluntary vaccination be attractively placed within the reach of all,

it would be monstrous to inflict upon the community compulsory submission to poor-law vaccination, a system which, from its unpopularity and meanness, can exercise only a very limited protective power. We do not require an extension of the present worthless system, but the maintenance of a supply of good lymph, and the careful and repeated examination, by skilful, conscientious, and remunerated medical officers, of each case operated upon. Let public vaccination, under these conditions, be offered to the public; and when vaccination under these conditions has been rejected, it will be time enough to discuss the necessity of a compulsory bill. The remark of Mr. HINGSTON is strictly correct:—

“If his lordship would inquire into the circumstances of the case, he would learn that the chief want among medical men is that of genuine lymph. During the present week, I have received two letters, one from Mr. Wilson, of Runcorn, Cheshire, and the other from Dr. John Grigor, Nairn, N. B., both complaining of the inefficiency of the lymph they use, and begging for a more effective supply of it from Mr. Badcock's stock. These cases are not solitary, and they exclude the idea of any advantage being derived from compulsory vaccination.” [Vide p. 335 of this number.]

The bill is unworkable in its machinery; because it attempts tyrannically to impose onerous gratuitous services upon the medical profession. The poverty of some and the thoughtlessness of others make many of our body accept poor-law appointments at non-remunerative rates; and the mad scramble of an overstocked profession tempts too many of our young physicians and surgeons to go cap in hand to hospital governors, beseeching to be nominated to perform an amount of gratuitous duty which, if not fabulously described in the printed reports of our hospitals, is so vast as to require for its even tolerable performance almost superhuman physical powers, as well as the entire surrender of every other professional occupation. It is not remarkable that Lord Lyttelton, cognizant of these facts as the chairman of a rural board of poor-law guardians, and as a peer of Parliament, should think it kind to impose any amount of unpaid work upon “medical officers and practitioners”, and believe that he is giving them that which they most ardently desire, because it is that which they are always most clamorously seeking to obtain. We must, however, for the sake of truth, declare that medical gratuitous services, like all other gratuitous services, are of comparatively small value. Parliament may, in the magnitude of its power and wisdom, decree that “medical officers and practitioners” are to perform certain work “without fee or reward”; they cannot, however, secure the efficient performance of that work, unless it be adequately paid for. Lord Lyttelton must be profoundly ignorant of human nature, and of the practical working of the present system of poor-law vaccination, if he fancy that such a clause as the following can supply any part of a machinery calculated to diminish the spread of small-pox. The following is an extract from the bill, which will be found *in extenso* at p. 264 of our number for March 25th:—

"That in the event of a child becoming sick or indisposed in consequence of having been vaccinated as aforesaid, then and in such case it shall be the duty of the medical officer or practitioner who vaccinated the said child, to attend upon and prescribe for the said child during such sickness or indisposition, and to furnish it with such medicines as may be necessary for its recovery, without fee or reward other than is provided for by the above-mentioned act."

The "fee or reward" here referred to is the EIGHTEEN-PENCE which at present "the guardians of the poor" are legally obliged to give to their vaccinators for each successful case—the paltry amount of which sum, as any man of reflection must perceive, is in itself an explanation of much of the worthlessness of the existing system.

We trust that none of our brethren, rendered impatient by the apathy of the poor and the prejudices of the ignorant, will stand aside with folded arms whilst Lord Lyttelton's Bill is being hurried through Parliament; for assuredly they will be among the very first to regret and condemn its enactment, and to discover that they have allowed a rod to be put in pickle for their own backs. It will then be too late to deplore "great injustice to the profession".

To our colleagues who hold appointments as vaccinators under the existing acts, we would say: Arise, shake off your torpor, emancipate yourselves from the fear of "the Guardians", and, like honest men and members of an honourable profession, declare in the face of the world that which you feel in your hearts to be too true: that the public safety from small-pox can in no degree be promoted by Parliament rendering your remuneration—already inadequate—still more inadequate by an increased burden of repulsive duty.

To men who, like Mr. Ceely, of Aylesbury, have devoted a lifetime to the enlightened study of the vaccination question in its hygienic, pathological, and political bearings, we would say: Give the profession and Parliament the benefit of your opinions without delay.

And to Parliament we would say, with respectful earnestness: Attempt not to legislate upon this momentous subject till you have examined witnesses, and till the evidence collected by the Epidemiological Society has been published and deliberately discussed by the Provincial Medical and Surgical Association throughout its Branches and in its General Assembly. Be thankful that there exists a society of two thousand medical men able and willing to assist in your deliberations. But remember that without their co-operation and sympathy, your most stringent or theoretically perfect Vaccination Act must only prove impotent and delusive.

THE MEDICAL REFORM BILL.

FROM among the numerous letters which we receive every day upon the subject of the Medical Reform Bill, we could select a mass of opposing opinions, such as would startle many who have not discovered the difficulty of the subject by studying it for themselves. Notwithstanding, however, the variety of sentiments entertained by different individuals and different classes of practitioners, there is one point on which there seems to be complete unity of opinion; viz., that the time has now arrived when all sections of medical reformers ought to join together in endeavouring to carry such a measure as may be an improvement upon the present condition of medical affairs, even though it

should fall short of their own standard of that which is required. In other words, the prevailing opinion seems to be that, considering the mixed constitution of the Committee of the Association entrusted with the Bill, and considering the promise which Lord Palmerston has given, that if the profession can arrange their differences, he will bring it forward as a Government measure—in consideration of these two points, all seem inclined to merge individual bias, when they find that it militates against the success of a measure which all may fairly accept as a boon, even though they look upon it as a mere instalment of reform. We believe that we are echoing the wishes of all our colleagues when we say with Dr. G. Webster—

"I would rather accept the Bill (with the improvements which it might receive in Parliament), as a very large instalment of what is due to the profession, and to the public interests, than see an agitation continued which is detrimental to both."—ASSOCIATION JOURNAL, 1st April, p. 285.

We regret to observe that the *Medical Times* is assuming that the Bill to be brought into the House of Commons is to embrace certain unpopular provisions, which there is no evidence that it is to contain. For example, we read as follows:—

"The Bill of the Medical and Surgical Association, while professing to be founded upon large and liberal principles, sweeps away every vestige of representative government from the ranks of the profession; and while the Colleges are to be strengthened in their privileges, and confirmed in their rights, the general practitioners will be deprived at once of any rights or privileges whatever. They are to be handed over wholesale to the regius professors of Oxford and Cambridge, to the College of Physicians and the College of Surgeons, and to other parties, none of whom, so far as we have learned, has ever evinced the slightest regard for the scattered multitude of homeless wanderers, who are thus unceremoniously to be thrust upon them."—*Medical Times*, 2nd April.

So far as we understand the present position of affairs, our esteemed cotemporary has, in this passage, created a man of straw, that he might have a tangible enemy against whom he might discharge his rhetoric. He has ventured to criticise a Bill, regarding the exact provisions of which he is ignorant, and regarding which we are also in the same predicament. It will be quite time enough to join issue upon the merits of the Bill, when we know exactly what alterations are made by Lord Palmerston previous to his presenting it to the House of Commons. It will then likewise be quite early enough for the *Medical Times* to seek a shelter for the "homeless wanderers". This seems to have occurred to our cotemporary himself, for in last week's number we observe less about opposition to the Bill, and find hopes expressed that it may be improved before it is presented to the House of Commons. The following passage warrants this observation.

"From the contents of Dr. Webster's communication, it appears that the Bill is still open to amendment, and that its authors are by no means agreed among themselves as to the propriety or expediency of many of its clauses; we may therefore hope to see many very important alterations made in the measure before it is presented to the House of Commons.

"We cannot but take credit to ourselves in having been the first, and, indeed, the only medical journal which exposed the defects of this measure; and, if we shall succeed in retarding its progress until very sweeping changes are effected in its provisions, we conceive that we shall be doing a great service to the general practitioners of this country."—*Medical Times*, 9th April.

We are not disposed to take any other ground than that occupied by the writer of this passage. By all means, let all do their best to get the Bill framed according to their own fancy; but let there be, at the same time, a distinct understanding that we are to settle all our disputes within our own camp, and are then to go forward with unbroken phalanx to the gates of Parliament.

THE NEW CHARTER OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

To-day we publish, *in extenso*, the Charter which the College of Physicians wish to obtain, and also the official report of an interview, on the 6th instant, between a deputation from that body and Lord Palmerston, the Home Secretary. In connexion with the general measure of Medical Reform, these documents are of great importance, and well deserve to be carefully considered by the members of the Association.

The Charter is conceived in a liberal spirit. If it were possible to judge of it as a distinct measure, we would unhesitatingly join with Dr. Hawkins in submitting,

"That as the object which the College has in view is one in respect of which no opposition is to be anticipated, it might be as well if the Government would direct their attention to it before they took in hand any other matter relating to medical affairs, which might give rise to diversity of opinion."

But the proposed Charter cannot be contemplated apart from the new Bye-Laws of the College of Physicians or the proposed measure of Medical Reform, adopted by our Association and the great body of the profession, as the result of the deliberations and mutual concessions of parties hitherto unable to co-operate. Although there is nothing in the Charter which we have much inclination to cavil at, yet we may be allowed to remark that some of its provisions seem to be inconvenient and unnecessary. For example, may we ask why the President is to be chosen from among the fifty senior Fellows? * And why is it deemed expedient or necessary to give to the College of Physicians the power of conferring degrees in medicine? † The bodies which exercise this right are already, in the opinion of many, too numerous.

As membership of the College of Physicians, under the proposed Medical Bill of the Association, is to be stringently enforced upon all those who practise medicine, it behoves us to take care that, through inadvertency, the details of one measure do not clash with those of the other, or operate with unintended harshness in certain quarters. We would also suggest that, if the great mass of the profession who are to be compulsorily attached to the College are not to be granted any share in the management of the College affairs, great injustice will be committed, and great dissatisfaction will be felt. Unless a more secure representation of the profession be provided for within the College than is necessarily involved in the new Charter, the College will not be able to place itself in its legitimate position at the head of the profession. A difficulty will also arise regarding that part of the Bill of the Association which

obliges practitioners to belong to the College of Surgeons or the College of Physicians. The safety of this provision may be endangered by legislation being cramped by an inelastic charter, previously granted to the College of Physicians. This is a point to which, in compliance with the wishes of many correspondents, we have thought it right to direct attention.

Again, so much will depend upon the new Bye-Laws of the College, that it would be well that the proposed alterations of the existing code were laid before the profession. For it is here that the question arises in all its magnitude, What is to become of the general practitioner? Is he to be extinguished for the benefit of the College of Physicians and the Pharmaceutical Society? Or is the College of Physicians so to modify its Bye-Laws as to allow physicians, when convenient to themselves and their patients, to use their own medicinal instruments, as Sir Benjamin Brodie and Mr. Syme are peacefully permitted to employ their own surgical instruments. We are no advocates for medical or surgical practitioners retailing jalap or bougies; but we are quite sure that it is equally for the advantage of the public and the profession that there should be no badge of inferiority affixed to those who, while they charge only for attendance, think it best, from motives of conscience or convenience, to administer their own drugs. The universal discontinuance of charging for medicine, and the substituting of the more professional system of the practitioner being remunerated only for his advice and attendance, would meet with no opposition from the profession (as the inquiries instituted by the Medico-Ethical Society of Manchester incontestably prove, so far as that populous town is concerned). But any attempt to prohibit non-commercial pharmacy would be strenuously opposed, because, in the present state of society, it would ruin the majority of the medical practitioners of England, and at once complete the elevation of the druggists to the position occupied by their predecessors before 1815, when they were the physicians and surgeons of nineteen-twentieths of the whole population.

HOSPITAL ABUSES:—A GLANCE AT NOTTINGHAM, BATH, AND BOLTON.

It is a source of extreme gratification to us, that the remarks we have felt it our duty to the Association to make upon the above subject, should have received so prompt and hearty a response, as our daily correspondence shews.

The evil is certainly one which, from its magnitude, requires the calmest feelings to deal with it—the promptest and kindest treatment. The profession, as a body, have so long permitted themselves to be grossly imposed on by an unthankful public, and the difficulties surrounding the discussion of the subject are so numerous, that a fear naturally arises on the part of those who are prepared to cope with the difficulty, as to how they shall proceed without transgressing the limits of medical benevolence, and thus appear to their patrons and benefactors anxious to restrict those acts of disinterested kindness which it is equally the privilege and the duty of our profession to render. There can be little doubt, that our bounden duty to ourselves, our neighbours, and our profession, requires that we, who see the imposition practised in the out-patients' rooms, should, on every occasion, point out this imposition to the committees

* Chapter XIV.

† Chapter XXXI:—"And such person shall, after his admission as a member of the said corporation, be entitled to have and use the degree or designation of Doctor of Medicine."

of those institutions which come more immediately under our notice. Let us begin by taking a case in point from a pamphlet which has been sent to us, entitled a *Report of the Nottingham Dispensary*.

What can be a greater abuse than the plan of drawing teeth practised at the Nottingham Dispensary? "Out of 3,634 cases paraded in the report, 1,445 are cases of tooth drawing; which class of cases," we are quoting this year's report, "though very numerous, has not been noticed by this institution until last year." Why, we would ask, should the surgical staff of the Nottingham Dispensary be called upon to deprive themselves, or their neighbours, of the small fee charged by dentists and general practitioners for this operation? or why should they, if the patients are really poor, act as gratuitous assistants of the poor law medical officers?

Dr. Davies, of Bath, in his letter, inserted at p. 285, admits the evil of the present system, and hopes that a remedy may be found. We would suggest one: let the medical staff represent to the committee the necessity of appointing a clerk to register all the applicants and furnish them with numbered papers, containing such particulars as that in use at the Bolton Infirmary, kindly forwarded to us by Dr. Black, and published at p. 285 of our number for 1st of April. In cases where imposition is suspected, let it be that clerk's especial duty to make inquiries at the applicant's residence: for as long as no recommendation is necessary, and the patient waiting his turn has merely to see the physician or surgeon and obtain his medicines, deceptions will be practised, which it is the duty of the medical officer to point out to the committee, although he is not able to suggest a remedy.

Gentlemen seek a place upon these committees, with ardour. Let them remember that their duty embraces something more than merely seeing if the patients are orderly in their seats. They should examine for themselves such persons as the physician, surgeon, or clerk, may invite attention to; and consider it as much their duty to see that the funds of the charity are not improperly expended upon those who can pay, as it is that of the medical officers to attend to the sick. One member of the committee should always visit the waiting-rooms daily during the out-patients' attendance. Look at the vast amount of needless labour imposed on the physician and surgeon who, by the parsimony of a committee, are called on to register indiscriminately all who apply for advice at a large public hospital.

Once more, let us call upon our colleagues to unite with us in exposing the present state of our public charities; let them take every opportunity of pointing out the abuses of the system, so that by a firm cooperating movement hospitals and dispensaries may be placed on a proper footing, both as regards the profession, and the really deserving poor. So long as committees look only to numbers admitted, and the professional attendants prescribe indiscriminately for all who present themselves, it is idle and futile to expect amendment: it is a cause which concerns all our interests; a cause in which those attached to public charities should unite with their non-official brethren before the whole profession is involved in one common ruin.

We intend again and again to return to this subject. In the mean time, we sincerely thank those who have so willingly cooperated with us in bringing the evils of the present system under the notice of those who have the power to mitigate them. We particularly thank the editors of

provincial newspapers, who have republished our articles and called attention to the abuses which were being allowed to grow luxuriantly without an effort being made to check them.

DR. GOLDING BIRD AND PULVERMACH'S ELECTRIC CHAIN.

DR. M'INTYRE has addressed to us a letter regarding certain advertisements of Mr. Meinig, the proprietor of Pulvermacher's Electric Chain, which have repeatedly appeared in this Journal, and one of which was inserted on March 25th; and was also received for repetition in to-day's publication. In the advertisements referred to, Mr. Meinig prints a testimonial from Dr. Golding Bird, in favour of Pulvermacher's Electric Chain, and announces that he does so by the "kind permission" of that gentleman. Dr. M'Intyre impeached the authenticity of the testimonial, and protested against its admission into our advertising columns.

In these circumstances, we lost no time in communicating with Dr. Bird upon the subject; and we now feel that the character of this Journal, and of various individuals, is so much involved in the disclosures which have resulted from our investigations, as to render it necessary to lay the whole particulars before our readers.

The following is the letter which we received from Dr. M'Intyre.

I. DR. M'INTYRE TO THE EDITOR.

SIR,—I am sorry to be under the necessity of drawing your attention to the advertisement of "Pulvermacher's Hydro-Electric Chain Batteries", which has been appearing very frequently in the pages of the JOURNAL.

In it is given the extract of a letter, purporting to be from Dr. Golding Bird, and which, professing to come from so high an authority in such matters, is calculated very much to mislead the members of the Association and profession at large.

A short time ago, through the kindness of my friend Dr. Cowan of Reading, I had the opportunity of seeing Dr. Golding Bird's disavowal of ever having written such a letter, or having in any way given his approval of the instrument.

As the JOURNAL is not a commercial speculation, but the organ of communication betwixt the members—having the dissemination of truth and the advancement of science for its primary objects—I think myself justified in protesting against the admission of that into its pages, which is calculated to destroy, instead of promote, such laudable purposes.

I am, etc.,
JOHN M'INTYRE, M.D.

Odiham, March 31st, 1853.

In consequence of this letter, we communicated with Dr. Bird, who promptly put us in possession of the whole facts of the case. We have permission to print his letter, though it was originally addressed to the editor in his private and not in his official capacity.

II. DR. GOLDING BIRD TO THE EDITOR.

MY DEAR DOCTOR,—I feel bound to reply immediately to your inquiry—how far I have "sanctioned the advertisement of Pulvermacher's Chain"? I can best do so by giving you a brief history of this "chain" so far as I am mixed up with it.

In 1851, Pulvermacher, a man of great scientific attainments called on me with a letter of introduction from a German physician settled in London. He had but recently arrived from Vienna, and scarcely understood a word of English. I examined his apparatus, and submitted it to experiment. The one I used, the only one, indeed, that I

was then acquainted with, was composed of one hundred links ; and I subsequently described it in the *Lancet*, (Oct. 1851, p. 388.) Some time afterwards a person whose name I never knew, but who described himself as a friend of Pulvermacher's, called upon me and requested a letter of introduction to Dr. Christison and other eminent physicians at Edinburgh, as he was anxious to introduce the apparatus to their notice. I accordingly gave him a written opinion of its value as a source of electricity, in the form of an introductory testimonial. Two or three lines have been selected from this for the purpose of appearing in the advertisements of Mr. Meinig, not only without my authority, (as I would never have sanctioned its appearing in an advertisement in the public papers,) but as you will see by the accompanying letter, it now continues to appear in opposition to my expressed prohibition. Indeed, I wrote to Mr. Meinig, to threaten legal proceedings with the view of obtaining an injunction, to prevent this public use of my name. I need hardly say how much vexation has been occasioned me by seeing my name employed to support the pretensions of what is now a quack remedy—for surely that term is not too strong for an apparatus which is declared to cure a large proportion of the diseases in our nosology, and many of them instantaneously.

The "chains" usually sold are too feeble to afford a sensible shock or even any physiological sensation ; they are, moreover, often directed to be worn round the body, in which case, as every link would come in contact with the skin, no concentration of force, no current, would be developed at the poles.

The battery of Pulvermacher is an ingenious and useful source of electricity, but nothing more. It can only be of use in those ailments where electricity itself is indicated ; and must fail, as a necessary consequence, in cases unfitted for electrical treatment.

I never before paid so heavy a penalty for giving a certificate to any one. In one week, shortly after the first appearance of the advertisement, I had nearly one hundred letters of inquiry. Even now, a week never elapses without my receiving one or two. These became such a source of trouble and expense, that I have long since declined answering them, except when sent by medical men.

I can only deeply regret that a certificate given in good faith to recommend a scientific instrument to the notice of our profession, should have been employed to advocate it as a quack remedy. As I stated in the *Lancet*, in 1851, "It must be recollected that the current evolved has no peculiar properties, and that it will effect nothing more than that evolved by any other means. It is, indeed, deeply to be regretted that so convenient a source of electricity runs the risk of losing favour in the sight of educated men generally, and of our profession in particular, by being injudiciously puffed in the public prints, by advertisements claiming for it a medical influence it in no wise possesses."

I am, etc.,

GOLDING BIRD.

4R, Russell Square, April 4th, 1853.

The whole affair is made very plain by the following letter from Mr. Meinig to Dr. Golding Bird, in reply to one from him, prohibiting the use of his name in advertisements.

III. MR. MEINIG TO DR. BIRD.

SIR,—When you had the kindness to give my agent your highly favourable testimonial on Pulvermacher's chain, you expressly authorised its publication "*whenever and in what manner I might find it useful*". I need hardly observe that a testimonial of this description, from a man of so high standing in the scientific world, is a great acquisition to any remedy, however excellent in itself, and particularly in deciding its rapid extension and acknowledgment ; and, in striving towards this end, I have used it freely, according to the understanding on which I received it. Should I now at once cease to publish such a testimony, I would be in a very different and unfavourable position to what I was before I got it ; for, say what we may, no one would believe

that consulting letters would be disagreeable to a practising physician, and all would attribute your withdrawal to a discovered inferiority in the remedy. I have, besides, every reason to believe that many other highly gifted men would have been glad at the time to introduce and associate their names with an invention like this—an advantage that I renounced when I received your testimonial with unqualified permission to use it.

Anxious, therefore, as I am to oblige, I cannot withdraw the copy of your words from the advertisement, which I am sorry to find you consider of a puffing description, but for which, of course, no other is responsible than myself. Should you wish it, I shall send to your house for the letters as often as you like, and answer them ; or shall have answers printed according to your directions, and shall of course pay any postage incurred.

I feel very grateful for your kind advice not to recommend the chain in diseases which it would be sure not to relieve ; but to my knowledge I have never done such a thing. On the other hand, to deny or withhold facts, passed a hundred times under my own eyes, because they may not correspond with theories founded on the observed effects of other forms of electricity, would be neither fair nor manly. That the chain acts only by electricity, is acknowledged on all parts ; but it cannot surely have escaped your notice, that the mode in which the chain, when wound, for instance, round a limb, affects the same electrically, is without a parallel in former apparatus ; and if the old machines and apparatus have been found to stimulate highly, and have therefore not been considered indicated in diseases depending on an irritated state of the nerves, it does not therefore follow that the mild, continuous, and combined currents, evolved from the chains for almost any length of time, may not have a different effect ; so that I cannot see any reason, even theoretically, to dispute what have to me, and to several medical men already, for some length of time, been established facts, when such negation is not supported by an overwhelming number of experiments showing it to be justified.

I beg to apologize for the length of this note ; but I would not let this opportunity pass without expressing, in a private way, what many considerations have prevented me from publishing in regard to some remarks in the *Lancet*.

I am, etc.,

C. MEINIG.

P.S. I received your note only yesterday evening, on my return from the country.—C. M.

108, Leadenhall Street, City,
London, December 1, 1851,

The documents now published make it plain that the advertisement, which has been appearing in our columns, is calculated to mislead the profession into the belief that Dr. Golding Bird's testimonial has a much wider meaning than it legitimately bears, and that it is paraded with his sanction ; whereas it is actually printed in opposition to, and in daring defiance of, his remonstrances. In these circumstances, the duty which we owe to Dr. Golding Bird, to ourselves, and to our colleagues, is very plain : it is, to interdict the repetition of Mr. Meinig's advertisements in the *ASSOCIATION MEDICAL JOURNAL*.

While candid readers will readily concur with us in acquitting Dr. Golding Bird of all moral blame, we do not think that he will be generally pronounced altogether faultless in this affair. The certificate was granted on far too easy terms, and without due precautions having been taken against the possibility of its being used for the puffing purposes of an artful speculator. Although intended only as a testimonial of the value of the apparatus as a source of electricity, without the slightest reference to its supposed curative powers, it has, by being ingeniously connected with lay certificates, been used to bolster up a claim to special remedial efficacy.

Medical practitioners would do well, as a matter of principle and uniform practice, to refuse all written testimonials in favour of new remedies, medicinal or mechanical. Many, we fear, sign certificates for the use of advertising parties, simply that they—the certificate givers—may have their names constantly placed before the public eye. It therefore behoves respectable persons, who wish to avoid the imputation of resorting to this modern system of gratuitous second-hand advertising, to abstain from all testimonial giving. It is impossible to exercise too much caution in this respect. Quackery is eagle-eyed, and ever on the alert cunningly to convert the names and the written opinions of professional men into trading capital, to be used in pillaging the public by various devices. Mr. Meinig, in attempting to appease Dr. Golding Bird by means of a sop, lets out—apparently quite unintentionally—the very mean estimate which he has formed of testimonial-giving doctors, and he also states the cheap advantages which he imagines may flow to physicians from being advertised second-hand. According to Mr. Meinig, to be incessantly advertised in connexion with an invention like the chain, is a privilege “which many gifted men would have been glad of”. Our own observation of the newspaper press—especially of the London Sunday papers, the provincial papers, and the colonial papers—convinces us that this system of being advertised second-hand, and for nothing, has grown into a regular system. Though not perhaps resorted to by very “gifted men”, it is, nevertheless, adopted by persons who ought, from their talents and their education, to soar above practices so mean and so unprofessional.

HER MAJESTY'S ACCOUCHEMENT: CHLOROFORM.

ON Thursday, the 7th instant, at half-past one P.M., the Queen was safely delivered of a prince. This announcement has, we feel assured, inspired among all classes feelings of interest and sincere gladness; but there are circumstances connected with the event which have likewise imparted to it no small degree of medical importance. We refer to the employment of chloroform having been sanctioned by Her Majesty's Physician in Ordinary, Sir James Clark, Her Majesty's First Physician Accoucheur, Dr. Locock, and Her Majesty's other Physician Accoucheur, Dr. Ferguson; to its having been administered by Dr. Snow; and to the fact of the Queen and the infant prince having gone on favourably from the first.

The following appeared in the *Court Circular*.

“Buckingham Palace, April 7.

“At ten minutes past one o'clock, this day the Queen was safely delivered of a prince.

“There were present on the occasion in Her Majesty's room—His Royal Highness Prince Albert, Dr. Locock, Dr. Snow, and Mrs. Lilly, the monthly nurse. In the adjoining apartments, besides the other medical attendants (Sir James Clark and Dr. Ferguson) were Her Royal Highness the Duchess of Kent, the Lady in waiting on the Queen, and the following Officers of State and Lords of the Privy Council, viz., the Earl of Aberdeen, First Lord of the Treasury; Earl Granville, Lord President of Council; the Duke of Norfolk, Lord Steward; the Duke of Wellington, Master of the Horse; the Duke of Newcastle, Secretary of State for the Colonies; the Marquis of Lansdowne; the Marquis of Breadalbane, Lord Chamberlain; the Duke of Argyll, Lord Privy Seal; Viscount Palmerston, Secretary

of State for the Home Department; and the Lord Chancellor.

“As half-past two o'clock the following bulletin was issued:—

“Buckingham Palace, April 7, half-past two o'clock, P.M.

“The Queen was safely delivered of a prince at ten minutes past one o'clock this afternoon.

“Her Majesty and the infant prince are well.

“JAMES CLARK, M.D.

“CHARLES LOCOCK, M.D.

“ROBERT FERGUSON, M.D.”

The following bulletin of the Queen's health was issued next morning:—

“Buckingham Palace, April 8, nine o'clock, A.M.

“The Queen has passed an excellent night.

“Her Majesty and the infant prince are going on favourably.

“JAMES CLARK, M.D.

“CHARLES LOCOCK, M.D.

“ROBERT FERGUSON, M.D.”

Subsequent bulletins have been equally favourable.

We understand that chloroform was administered by Dr. Snow during the latter part of the labour, with very satisfactory effect; and that the Queen expressed herself as grateful for the discovery of this means of alleviating and preventing pain.

The responsible position, and the acknowledged skill of the physicians who sanctioned the inhalation of the chloroform, the Royal Majesty of the patient, and the excellence of her recovery, are circumstances which will probably remove much of the lingering professional and popular prejudice against the use of anaesthesia in midwifery, even when sanctioned by competent authority, and induced with requisite precaution. It is for this reason that we chronicle the recent accouchement of Her Majesty as an event of unquestionable medical importance.

THE INCOME TAX PETITIONS FROM YORK AND LEEDS.

As some misconception has arisen regarding the Income Tax proceedings at York and Leeds, we insert the following official statement, kindly furnished at our request.

“At a Meeting of the York Members of the Council of the Yorkshire Branch, called by the Secretary, on the 1st of March, to take into consideration the subject of the Income Tax, it was recommended that the chief towns of the Branch should be requested to petition the House of Commons. A Petition, similar to that in the Journal of January 28th, was agreed to, and has received the signatures of nearly all the members of the medical profession in York. It will be presented to the House of Commons, and supported by the members for the city. Through the exertions of Dr. Chadwick, of Leeds, President of the Yorkshire Branch, a similar Petition, signed by sixty medical practitioners will be presented by the members for that town.”

WILLIAM MATTERSON, JUN.,

Secretary to the Yorkshire Branch.

ORIGINAL COMMUNICATIONS.

CASES OF ABSCESS OF THE SPLEEN,
WITH REMARKS ON THE PATHO-
LOGY OF THAT ORGAN.

By EDMUND LYON, M.D., Consulting Physician to the Manchester Royal Infirmary.*

OUR knowledge of the functions of the spleen, or of the purpose which this organ serves in the animal economy, is so extremely imperfect, and our diagnosis of its diseases consequently so uncertain, that it is desirable to record every fact which may contribute to throw a little light upon either: and it seems probable that through the pathology we shall find the most trustworthy way of exploring the physiology of this organ. With this view, I have thought it not unprofitable to draw attention to the subject, by shortly describing a case which appears to be of rare occurrence, and adding a notice of some similar cases, with a few remarks suggested by a consideration of the facts brought forward.

I regret that my memoranda do not enable me to give a more complete history of the following case.

CASE I. The subject was a married woman, aged 36, who was delivered of a first child, in April 1833, by a practitioner with whom I was not acquainted.

On July 17th, I saw the patient for the first time, in conjunction with Mr. Jordan, and learned the following particulars:—Since the birth of her child, she had never been well, having suffered much pain in the left side, and having seldom been able to quit her bed. There was felt at this time, below the ribs of the left side, a tumour, having an obscure degree of fluctuation. There were frequent shiverings, occasional vomiting, rapid pulse, thirst, and cough. She was very helpless, lying best on her back, suffering dyspnoea when laid on either side, or when sitting up for any length of time. The countenance had a very peculiar expression—a kind of smile mingled with anxiety. The complexion was of that appearance which Darwin likened to that of a full-grown silk-worm, and John Bell to modelled wax.

Palliatives only were thought advisable under these circumstances; and I did not see the patient again till September 3rd, from which time till her death, on October 8th, she continued to decline. During the last eight days of her life, she had a discharge, *per anum*, of very offensive matter, mingled with small blood-coloured vesicles; and after the commencement of this discharge, the tumour in the side disappeared.

Examination of the Body on October 10th, forty-four hours after death, by Mr. Jordan and myself. When the abdomen was laid open, a superficial view of its contents presented no marks of inflammation. The stomach was situated low down; and, on a close examination, its large end was found to have contracted adhesions to the adjoining textures. The small intestine was removed, and nothing remarkable observed in it. The adhesions of the stomach being torn up, a large cavity was exposed, bounded by the stomach, diaphragm, left kidney, and colon. There were no remains of the spleen, except its capsule, and two fungoid bodies, of the size of walnuts, lying over the kidney. The diaphragm was pushed far upwards, so as to diminish considerably the left cavity of the thorax. The sac contained a small quantity of turbid and very foetid matter; it communicated with the descending colon by a circular aperture, with smooth edges, capable of admitting the tip of the forefinger. The liver was pale; the gall-bladder contained a small quantity of light-yellow bile.

The substance of the lungs was healthy. The left lung was reduced in volume, occupying only the upper portion of the chest. The vertebrae did not appear diseased.

The obscurely fluctuating tumour, accompanied by hectic,

and preceded by acute pain, rendered the existence of an abscess almost certain; and the situation of the tumour led us to suspect the spleen to be the seat of disease. The evidence for both these suppositions was much strengthened by the nature of the discharge from the bowels during the latter days of life, and the simultaneous subsidence of the tumour. Yet, as neither of us had ever seen a similar case, it required the further evidence of anatomy fully to satisfy our minds as to the actual state of things.

The following case of suppurated spleen is related by Dr. Raikem, in the seventh volume of the *Repertoire d'Anatomie*; the leading points I quote from the *Medico-Chirurgical Review* for December 1829.

CASE II. A young man, aged 20, of a sedentary occupation, and a spirit-drinker, had inflammatory fever, with pain in the left hypochondrium, nausea, and vomiting, followed by a tumour and lancinating pain in the left hypochondrium, with yellow complexion, and evening exacerbations. The tumour extended till it reached the umbilicus, and at the same time became softer. It then diminished, and the pain was mitigated; "but the patient began to suffer from a sense of intolerable dragging, and constant lancinating pains in the left lumbar region, where oedematous swelling and deep fluctuation were discovered". These pains shortly ceased to be severe; "but the fever and other symptoms grew rapidly worse; the belly was blown up, and painful on the left side, from the hypochondrium to the groin. A hard, very painful, and circumscribed tumour appeared in the latter situation. The breathing became hurried, laborious, and attended with pain on inspiration. There was frequent dry cough; difficulty of lying on either side; rapid and weak pulse; diarrhoea"; and the patient died at the end of two months.

Examination of the Body. In the left cavity of the thorax were found more than two pints of yellow serum, with flakes of lymph; and the pleura was covered with false membrane.

In the abdomen "the superior portion of the descending colon, and the great end of the stomach, were closely united to the spleen. This latter viscus was double its ordinary size, and of vermilion colour on its borders. The peritoneum, opposite its posterior surface, was raised by a whitish, thick, purulent, and very foetid fluid, which was found to have issued from the cavity of a vast abscess in the substance of the spleen. From this it had extended between the peritoneum and the abdominal muscles as far as the kidney, the spine, and even as low as the crural ring".

CASE III. In the same volume of the *Medico-Chirurgical Review*, is quoted a case from Fantoni, of an abscess of the spleen discharging itself at the umbilicus. The patient recovered, bore a child, and lived five years afterwards. On opening the body, no vestige of the spleen remained; and the neighbouring parts were united by cicatrices in the usual situation of the missing organ.

CASE IV. Mr. Hickman, in the sixteenth volume of the *Medical Repository* (1821), relates a case, of which the following is an epitome.

A girl, of a scrofulous habit, at the age of thirteen, complained of pain in the left hypochondrium, which was soon removed under the care of Dr. Thorp. In little more than a year, she again applied to him, labouring under the symptoms of general dropsy. She was again relieved, but not cured. At length an ulceration appeared at the umbilicus, which discharged abundantly a thin glairy fluid, and some particles of undigested food. Three days before death, which occurred at the age of fifteen, Mr. Hickman saw her in excessive agony, arising from complete obstruction of the intestines.

Examination of the Body. Inspection of the abdomen discovered strong adhesions between the peritoneum and its contents. The transverse arch of the colon—callous and obliterated so as not to admit the smallest probe—adhered to the lower edge of the liver, which was the only organ having the slightest appearance of health. The stomach was in a state of universal ulceration, "adhering to, and communicating with the spleen, which was a mere sac, con-

* This paper was read before the Medical Society of Manchester several years ago; and is now communicated, with some additions, by Samuel Crompton, Esq.

taining pus and undigested food ; out of this sac it passed through the layers of the muscles to the umbilicus, so that all the food was either rejected, or took this course". The small intestines were a complete mass of disease, and reduced to very small dimensions. The blood-vessels of the abdomen were greatly enlarged, particularly the renal ; and in the left renal artery was found an aneurism. The heart was unusually large.

I will next advert briefly to some of the cases of like nature, collected by Dr. Abercrombie, in his *Contributions to the Pathology of the Spleen*.

CASE V. The first case came under his observation in the person of a gentleman, aged 52, who died after an illness of six months, during which there were no prominent symptoms, but progressive emaciation and weakness, with frequent pulse, and sometimes feverish nights. He had never complained of pain ; but, on being closely questioned, mentioned an occasional feeling of undefined uneasiness in the epigastrium. Three days before death, he was affected with diarrhoea.

Examination of the Body. The spleen was found enlarged, and in its centre was an irregular cavity, containing several ounces of pus ; the surrounding substance being soft and easily torn. The liver was pale, but otherwise healthy.

CASE VI. His next case is taken from the *History of the French Academy of Sciences* for 1753. A young man, aged 18, several months after his recovery from a quartan intermittent, was affected with slight fever and violent colic pains. He had then loss of appetite and sleep, laborious breathing, œdema of the legs, scanty urine, and enlargement of the abdomen. He was twice tapped, and each time four pints of pus were drawn off. He died the day after the second puncture. On dissection, the spleen was found enormously distended, extensively adherent, and forming a sac, which still contained seven pounds of purulent matter : the other viscera lay compressed behind it.

CASE VII. Another remarkable case, related by M. Coze, in the *Journal de Médecine*, tome lxxiii, p. 225, occurred in a man who had for several years endured pain, sometimes acute and sometimes obtuse, in the epigastric region, along with a feeling of pulsation at the stomach, which was increased by exercise, or by any excess in diet. He was easily fatigued, and a sense of suffocation was induced by any exertion ; and he had occasional vomiting. Nothing more than a slight tension across the epigastrium could be discovered by manual examination. Towards the close of his life, there was a slight yellow tinge of the skin. At length, he was seized with a vomiting of blood, mingled with pus ; and, for a fortnight felt better than he had been for years. The vomiting then returned ; and at the end of another week a third attack proved fatal.

Examination of the Body. The spleen was found adhering closely to the stomach, and forming a bag filled with pus and clotted blood. It communicated with the cavity of the stomach by a large opening at the point of adhesion.

CASE VIII is related by M. Jacquinelle, in the *Journal de Médecine*, tome lxxviii, p. 360. A youth, aged 17, after several injuries from falls, and a state of general disorder, complained of pain and fulness in the left hypochondrium, along with palpitation, faintings, and emaciation, and died about a year after the commencement of his disease. Before death, the pain ceased, and a quantity of dark foetid matter was discharged by stool.

Examination of the Body. The spleen was found much enlarged, adherent to the colon, and containing in its substance an abscess, which had burst into the colon at the place of the adhesion. The heart was also enlarged, and there was dilatation of the aorta.

CASE IX and X. Grottanelli records a case, in a girl of 12 years, in which an abscess of the spleen burst into the peritoneal cavity, and proved fatal in three days. In another singular case, mentioned by the same writer, a man who, after several attacks of ague, was supposed to have abscess of the spleen, received a violent blow on the

left side ; after which the tumour, previously existing there, subsided, and he discharged thick and foetid matter along with his urine for three weeks. He then recovered good health, and continued well seven years afterwards, when the account was published.

The following case, erroneously referred to in Dr. Monro's *Outlines of Anatomy*, as a case of abscess of the spleen, is recorded by Dr. Nathan Drake in the second volume of the *Edinburgh Medical and Surgical Journal*.

CASE XI. Mrs Newman, a widow, aged 49, of corpulent habit, and long subject to dyspepsia, on the 29th of October, 1805, soon after dining heartily on roasted pig, was seized with violent epigastric pain, sickness, and vomiting ; which, though mitigated for a time by the emptying of the stomach, returned in a few hours with aggravation, accompanied by severe lancinating pain under the left false ribs, and continued with few intervals until the next day, when Dr. Drake saw her. At this time the pain and vomiting continued, with a hot and harsh skin, thirst, white and moist tongue ; pulse 130, neither full nor hard. The bowels had been rather constipated for several days, and had not been moved at all since the commencement of the attack, notwithstanding the employment of powerful means for that purpose. The abdomen was distended, but no hardness or tumour could be felt. The urine deposited a copious lateritious sediment. There had been no rigor, ; and there was neither pain nor difficulty in breathing.

Various means of allaying the irritability of stomach, and opening a passage through the bowels were tried during the 30th and 31st of October. On November 1st, blood was taken from the arm, in quantity not exceeding six ounces, which, on standing, "exhibited a thin, concave, buffy surface" ; but the crassamentum was so dark and loose, and the pulse (130) so very weak, that the consultants* dared not carry the abstraction of blood any farther. On the evening of Nov. 1st, a small evacuation of the bowels took place, which during the next twenty-four hours was followed by fifteen more ; "and a prodigious quantity of black, knotty, and hardened feces" was evacuated. "The relief obtained was great ; the pain was removed ; the irritation of the stomach subsided : and the pulse sank to 80."

On Nov. 3rd, the pulse had again risen to 100 ; there was a little vomiting, but an extreme degree of acidity in the stomach. The pain of the left side was little felt whilst the patient lay upon her back ; but she could not lie upon her left side, even for five minutes, without an insupportable sensation of weight and dragging. The following week, pain and vomiting came on again in a severe form, and again subsided under the use of brisk purgatives ; which throughout the whole course of the disease afforded more relief than any other remedy that was tried.

The case proceeded with alternate aggravation and remission of the symptoms ; the stomach could receive only small quantities of food ; emaciation made rapid progress ; the skin was continually dry and harsh ; the tongue foul, with foetid breath, much flatulence, and great acidity in the *prima via*.

In the middle of January, the left ankle and knee were successively affected with severe pain, followed by œdema of the whole limb ; and during this time little pain was felt in the stomach or side.

In February the œdema had disappeared ; the pain in left side was occasionally, but not permanently severe ; distension and vomiting certainly returning with violence, if the purgative was deferred beyond the third day. The patient slept some hours every night, but could never lie on the left side ; emaciation and debility increased, but there was no hectic ; no tumour could be felt in the abdomen ; nor was there any discoloration of the skin ; tongue cleaner ; urine natural.

On April 8th, Mrs. Newman suddenly complained of a swelling at her stomach, with a sense of great fulness. On examination two days after, a considerable tumour was found reaching from the ensiform cartilage to the umbili-

* Drs. Clubbe and Drake, and Mr. Bunn.

cus : it was circular, prominent, and well defined, and had distinct fluctuation. On the following day, the tumour had subsided to half its former bulk, and therefore no operation was performed until the 17th ; when—the tumour having risen even beyond its former dimensions, and pressing upon the stomach so that not a teaspoonful of any thing could be retained, even for a minute—a trocar was introduced, and there were drawn off two pints of a fluid, free from fœtor, resembling thin diluted coffee in colour, and partially coagulable by heat.

After the operation, the patient was able to retain the usual quantity of food upon the stomach ; she passed the evening nearly free from pain, and had some sleep. But the following morning she began to sink, and early on the 19th she expired.

Examination of the Body a few hours after Death. The omentum was greatly thickened by the deposit of a granulated caseous matter, extending lower down than usual, and strongly adherent to the peritoneum generally. The stomach was nearly three times its ordinary thickness, and its capacity was reduced in the same proportion. The organization of the spleen was destroyed ; its peritoneal coat was dilated into a large cyst, with bloodvessels of enormous size ramifying on its fundus. "The upper part of the cyst strongly adhered to the whole under surface of the stomach, and the lower part to the upper edge of the great arch of the colon. The diameter of the cyst was full six inches, and it contained more than a pound and a half of dark, dense, coagulated blood, several portions of which, nearly as large as a man's fist, floated in a brown-coloured serum, of which there was better than a pint." "The bottom and sides of this bag were covered about an inch deep with a black tenacious matter, of the consistence of congealed honey ; which when examined with the fingers, was found interspersed with masses of the same caseous substance which covered the omentum."

The stomach and liver were both pressed upwards, and the arch of the colon thrust several inches below its natural situation, and so contracted in diameter, "that when the body was opened it projected like a chain of very small bladders". The blood-vessels on the arch of the colon were turgid ; and the mesocolon was diseased like the omentum.

There was no communication between the splenic cyst and any of the adjacent viscera ; its contents were not fœtid ; nor was any pus discovered there, or elsewhere.

It may be remarked that, in all the cases of suppuration in the spleen now produced, the progress of the disease was slow. In fact, acute *splenitis* has been so seldom noticed, that we may fairly infer, either that it is very uncommon, or that its diagnosis is difficult. Hence Dr. Abercrombie was led to conjecture that abscess of the spleen was necessarily preceded by a state of induration and enlargement, or by tubercular disease ; whilst the more rapid and acute forms of disease involving this organ appeared to terminate in a state of *softening*, in which the substance of the spleen is broken down into a semi-fluid resembling melted pitch, or black-currant jelly, contained within its peritoneal covering as in a bag ; such as is frequently observed in fatal cases of typhus, and other fevers. This opinion of Dr. Abercrombie's may or may not be well founded ; but it derives no great degree of support from his own case, in which a central abscess was found, and the surrounding substance soft and lacerable ; and in other cases we have every degree of variety, from entire destruction of the organ, to the existence of many or few small suppurated tubercles.

Our diagnosis of this disease must still be considered imperfect ; but its presence may be strongly suspected when the following symptoms concur in any individual : pain in the left hypochondrium, accompanied or followed by a tumour in which any degree of fluctuation can be detected ; tension in the epigastrium ; dyspnoea ; vomiting ; hectic fever ; emaciation ; and debility. Hackman* mentions as a constant symptom of enlarged spleen, a sense of distressing fulness in the præcordia, with dyspnoea, which is

sometimes so intense as to amount to orthopnoea. Mr. Twining* has remarked that in engorgement of the spleen, as observed in Bengal, "the respiration is low, languid, and imperfect, the lungs being but partially filled with air".

To the above symptoms I was at first inclined to add the peculiar change of complexion noticed in the case which occurred to Mr. Jordan and myself ; but I cannot, on the strength of a single case, venture to do more than recommend attention to this point by future observers of diseases of the spleen. This caution, in drawing inferences from isolated facts, is more especially necessary on the present occasion, as Abercrombie, from his own experience, was disposed to attribute a similar appearance to disease of the pancreas ; and perhaps it may be found that this complexion accompanies a state of anæmia, from whatever cause, not at all dependent on disease of any particular viscus. Nevertheless, it is worthy of being mentioned, in corroboration of an opinion that the spleen has more to do with the change in question than any other organ, that Mr. Twining, in the paper already referred to, speaking of *congestive engorgement* of the spleen, describes the face as being "of a pallid and lurid colour", and "the skin cool, with a peculiar dry feel, like a thin satin loosely laid over the soft cellular structure". Dr. Vetch† also, in his account of enlargement of the spleen succeeding the Walcheren fever, after saying that the "features have a peculiar dark, bilious, or mahogany hue" (which does not serve our present purpose), proceeds to observe, that "perspiration is in time wholly suspended, and the skin acquires the appearance and feel of satin" ; an appearance which Jackson likewise noticed in convalescents from the remittent fever of warm climates, in which we know that the spleen is apt to suffer vascular engorgement, or more serious derangement of its structure. Lastly, Dr. Crane has remarked, that the inhabitants of Lincolnshire are often affected with enlargement of the spleen for many years, without exhibiting much appearance of disease beyond a pale or yellowish aspect. These remarks, however, apply more to congestion of the spleen accompanying intermittent and other fevers, than to splenitis or abscess of the spleen.

The following case presents some interest with regard to this subject.

CASE XII. A female of delicate constitution, aged 25, had been subject to rheumatic affections ; and in the spring of 1835 underwent a good deal of fatigue and hurry, at a time when she had not completely recovered from an attack. She was never entirely well afterwards : she became languid and pale ; lost her appetite ; ceased to menstruate ; and the heart's action was accelerated by the least exertion.

When I first saw her, about the middle of November, she had been confined to bed, on account of feebleness, a few weeks. The pulse at the wrist was 120, and the impulse of the heart rather strong. There was no difficulty of breathing, very little cough, and scarcely any pain ; but the stomach with difficulty retained the lightest kind of food. There were profuse perspirations ; and the complexion was remarkably pale, with some tendency to œdema. Pretty large doses of an opiate were required to procure sleep.

The perspirations were checked, but the pulse never fell below 100, though the heart's impulse was diminished in force. The stomach became so irritable, that vomiting was excited by everything that was taken, except the opiate ; and for some time the only nourishment was administered in the form of clysters : perhaps a small portion of toast-water might also be retained.

A seton was inserted below the left breast, and various medicines were tried in succession : effervescent salines, acidulated drink, hydrocyanic acid, a blister to the epigastrium, dressed with acetate of morphia, and chalybeates cautiously administered. The saline draughts and the opiate seemed to be most useful ; and latterly the oxide of bismuth, in the form of lozenge, seemed to have the effect of putting a stop to the vomiting for a longer time than anything else had done.

* Transactions of the Medical and Physical Society of Calcutta, 1829.
† Medical and Physical Journal, 1824.

The patient died, exhausted, on January 1st, 1836.

Examination of the Body, Jan. 4th. There was effusion of serum, on both sides of the chest, to the amount of more than a pint, and in the pericardium three ounces. A large part of the fluid probably exuded after death. The lungs were crepitant and healthy, with the exception of some inflammation in the bronchial tubes. The heart was of natural size, rather pale and flabby. The lining of the right auricle, at the base of the tricuspid valve, was roughened and red, and covered with a loose kind of substance, which could be scraped off. A slight degree of the same appearance was noticed on the valves of the aorta. The spleen was enlarged, redder and harder than natural; at the upper end, just under the capsule, was a body of the size of a small nut, consisting of a soft curdy matter contained in a cyst, which might be considered as a softened tubercle; at the lower end were several similar bodies, in a less advanced state. A section through the spleen showed the whole viscus to be diseased, presenting a surface of various degrees of redness; the lighter red being softest, and the darker minutely speckled with whitish spots. The liver was very pale; the gall-bladder filled with dark green bile. The stomach was pale externally; internally it exhibited some redness at the cardiac end. The rugæ were nearly obliterated; here and there were a few black lines, as if traced with Indian ink. The kidneys were perfectly healthy. The pancreas was perhaps a little harder than usual.

I have twice met with tubercles in the spleen.

CASE XIII. A girl of nineteen died in the Manchester Infirmary, under a complication of disease. I am indebted to Mr. Gaskell* for some short notes of the case, and for the rest have trusted to my own recollection. She had always been a delicate child, of stunted growth, and had never menstruated. She did not, in fact, appear to be more than fourteen years old. Two or three years ago, she complained of a tickling cough, and pain at the stomach, especially if hurried; and, eighteen months before admission, her abdomen had become swollen. She was much emaciated, and the skin had a deep yellow tinge. The abdomen was greatly distended with fluid; the legs were œdematous; and the liver was felt as low as the umbilicus. In the left hypochondrium, also, a tumour of considerable firmness was perceptible. Her voice was husky, and she had cough, attended by expectoration of a transparent, jelly-like mucus, generally tinged equally throughout with red particles. The pulse was frequent, and epistaxis and hæmatemesis occasionally took place; there was constant nausea, and frequent vomiting; the bowels were sometimes affected with diarrhoea, and always loose, the feces being light-coloured. After being in the infirmary about six weeks, she expired in a fit of dyspnoea.

Examination of the Body. There was increased vascularity of the lungs, but no structural disease in them, nor in the heart. The liver was of a remarkable green colour, greatly enlarged, indurated, and presenting an irregular knotted appearance on the convex surface: a section exhibited a mottled appearance. The stomach was enlarged, and the softened mucous membrane furnished a good example of the brown discoloration from stagnant blood affected by the gastric juice. The spleen was five times its natural size; externally and internally, it was of a rather bright red colour, and was studded throughout with small yellowish white and softened tubercles.

CASE XIV. The other case occurred in the person of a boy named Henry Sunderland, seven years old, who, in the month of March 1818, received a cut on his head, and in April passed through the measles, after which he was never quite well, and died of hydrocephalus in July.

Examination of the Body. Messrs. Darnell and Boutflower assisted in the examination of the corpse, the general results of which it is not necessary here to specify. It will be sufficient to observe, that the spleen was studded throughout with granular bodies, somewhat resembling those in

currants, and consisting of a curdy matter contained in a cyst. If there had been time to examine the contents of the thorax, the lungs would probably have been found to contain similar tubercles. The kidneys were healthy; and so was the liver, with the exception of a portion on the convex surface, about the size of a shilling, and three lines in thickness, which was of a pale yellow colour, and a little indurated. The gall-bladder contained green bile.

In the treatment of diseases of the spleen, practical writers pretty generally concur in deprecating the use of mercury; and Mr. Twining, in particular, says that, in the state of constitution attending vascular engorgement of the spleen, the action of mercury is apt to induce alarming debility, with a tendency to sloughing of the lips, cheeks, and gums, which, when once commenced, has frequently, or rather generally, a fatal termination. This state of constitution, he says, is often seen in children, as a consequence of "damp climate, want of exercise, bad clothing and feeding, etc." It might be deserving of inquiry, whether the sloughing of the cheeks, and other soft parts, in some children of this country, is in any degree connected with a similar state of the spleen.

I do not mean to dwell at great length on the subject of the physiology of the spleen; since the best opinions on the subject amount to little more than plausible conjectures. The doctrine which has been most commonly taught is, that the spleen acts as a sponge, serving the purpose of a reservoir for any occasional superabundance of blood, so as to preserve other important organs from over-distension; and that it likewise serves to regulate the supply of blood to the stomach and liver, according to the necessities of these organs in the different stages of digestion. This, I believe, was Dr. Haighton's opinion; and it is supported by the experiments of which Mr. Dobson published an account.

He observed that, four hours after a full meal, the spleen in a dog is much enlarged, and attains its maximum in five hours.

The spleen of a dog was removed. On the following day, the animal was allowed to eat voraciously. For three hours afterwards, no inconvenience was manifest; but in four hours the dog became restless, and then sank into a nearly torpid state. "It was often moaning; the pupils were dilated; the heart labouring; there was frequent micturition; the respiration was exceedingly laborious; and, in short, there was every mark of plethora, or overfulness of the vascular system." A full meal was taken twice or thrice every twenty-four hours, and each was followed by similar effects. In a month after the operation, the dog died.

In a second dog, whose spleen was removed, the plan of giving small quantities of food every hour or two was pursued for three weeks, at the end of which time the animal appeared quite well, and had become fat. The same mode of feeding as in the first case was then adopted, and the effects were similar, but not so severe. The dog died in a month from the commencement of this plan of feeding.

It may here be mentioned (though a little out of place), that Mr. Dobson had an opportunity of examining the spleens of two great ale-bibbers, and found them very much enlarged: in one case so enormously as to give the idea of "a bladder half filled with oil".

The above-cited doctrine seems to me too mechanical to be received as a full and satisfactory explanation of the use of the spleen; though we may readily admit its regulating power to be one of the useful purposes that it fulfils in the animal economy.

Pemberton, in his work on *Diseases of the Abdominal Viscera*, states his belief that the spleen is a gland of supply. Among the testimonies in favour of this view, may be mentioned the observations of Mr. Twining, and more especially those of Dr. Vetch. The former gentleman says that, in the state of disease described by him, the appetite for food is not deficient, "but assimilation is imperfectly performed, and nutritious food does not restore the strength". Dr. Vetch says that a patient affected with

* Now one of the Commissioners of Lunacy.

enlarged spleen has generally a good appetite, "yet his powers of assimilation are obviously deficient; he loses flesh, and is incapable of any muscular exertion"; "the lips are pale, and there is generally much wasting of the gums; the urine is limpid, and secreted very rapidly, but contains little or no *urea*". This is a state of the system often observed in connexion with amenorrhœa. Dr. Vetch further observes that, "without the co-operation of the spleen, the blood ceases to acquire its recrementitious properties, none of the secretions possess their natural constituent parts, and—what is also worthy of notice—external injuries do not produce the secretion of what is called healthy pus". This is in accordance with a favourite hypothesis of Hewson's, that the red globules of the blood are formed by the spleen and its appendages. Dr. Hewson's view has in late years been revived by Dr. Hughes Bennett, of Edinburgh, in a paper published in the *Monthly Journal of Medical Science* for March 1852. He believes, with Hewson, that the lymphatic glandular system consists of the spleen, the thymus, and lymphatic glands; and adds to these the thyroid gland, the supra-renal capsules, the pituitary and the pineal glands; all which he believes to have for their office the formation of the blood. The following are his conclusions:—

"1. That the blood-corpuscles of vertebrate animals are originally formed in the lymphatic glandular system; and that the great majority of them, on joining the circulation, become coloured in a manner that is as yet unexplained.

"2. That in mammalia, the lymphatic glandular system is composed of the spleen, thymus, thyroid, supra-renal, pituitary, pineal, and lymphatic glands.

"3. That in fishes, reptiles, and birds, the coloured blood-corpuscles are nucleated cells, originating in these glands; but that, in mammalia, they are free nuclei, sometimes derived as such from the glands; at others, developed within colourless cells.

"4. That, in certain hypertrophies of the lymphatic glands, their cell-elements are multiplied to an unusual extent; and, under such circumstances, find their way into the blood, and constitute an increase in the number of its colourless cells. This is leucocythæmia."

Professor Kölliker, on the other hand, in his article on the Spleen in the *Cyclopædia of Anatomy and Physiology*, part xxxvi, advances an entirely different view, namely, that the spleen is a destroyer, not a regenerator, of blood. He believes that the blood-corpuscles "undergo solution in the spleen, and that their colouring matter is employed in preparing the colouring matter of the bile". He grounds this theory on the circumstances, that the blood-corpuscles must be dissolved to make room for the new ones, and that not the least trace of this process has been seen in any other organ; that in no other way can any reasonable account be given of the changes which the blood undergoes in the spleen; that the author's hypothesis elucidates the relation of the spleen to the portal system of veins—the dissolved blood-corpuscles being subservient to the formation of bile; and that the diseased conditions of the spleen, and their operation on the organism, are thus better explained.

The correctness of this view of Kölliker's is denied by Dr. Hughes Bennett in the paper to which I have referred.

While, then, we find physiologists of such eminence so totally disagreeing as to the functions of the spleen, we must receive all opinions on the subject with caution. This organ has always been the puzzle of physiologists; and I do not think that it will yet lose that character. The subject, however, should be prosecuted with a zeal proportionate to the difficulties with which it is surrounded.

Manchester, April 1853.

LETTSOMIAN LECTURES FOR 1853.

By EDWARD WILLIAM MURPHY, M.D., Professor of Midwifery in University College, and Obstetric Physician to University College Hospital.

LECTURE THIRD.

THE IMPORTANCE OF A SCIENTIFIC MEDICAL EDUCATION TO PRACTITIONERS IN MIDWIFERY.*

MR. PRESIDENT AND GENTLEMEN,

IN the two preceding lectures, I have placed in review before you the phenomena of parturition, the difficulties that present themselves, and the manner in which labours are too frequently mismanaged. I have done so, in order to show you the irreparable mischief which an incompetent person can do, and to prove that a sound, nay, a high standard of medical education is too often necessary to counteract those sources of danger to which the parturient woman is liable. I have endeavoured to expose the convenient, but most mischievous sophism, "that parturition is a natural process, therefore education is not essential for the safe delivery of the parturient woman". I trust that I have convinced you what a frightful sacrifice of human life may be the consequence of this error; and if any doubt should exist, I hope, before I conclude this lecture, to remove it by the evidence of facts.

It now remains for me to direct your attention to the present state of obstetric education, which, I regret to be obliged to confess, is deficient in the extreme; so imperfect, so inadequate, that if some expansive and efficient means be not taken to improve it, the accidents will become so frequent; the public so indignant; the coroner so often called upon; the doctor, who parades a diploma, so often exposed, that I fear our whole profession may be dragged down from the honourable pedestal on which it ought to rest, into the deepest abyss of degradation—public contempt.

The history of midwifery in these countries proves that the public are gradually becoming more and more alive to the importance of education amongst those who profess to practise it. Formerly, the universal rule was to separate the practice of midwifery altogether from the medical profession. Medical education was not thought, for the reason I have stated, essential for security; and if such were true, there was the strongest, the most obvious reason, for discarding men altogether from obstetric practice. The charge of the parturient woman was therefore committed exclusively to the midwife. However, her incompetency to meet all the difficulties and accidents that presented themselves soon became manifest; medical men were called upon in emergencies; and those who, by close study and observation, prepared themselves to meet these contingencies—the Fathers of Obstetric Medicine—were called by no medical title whatever; they were neither doctors nor surgeons, but simply "men-midwives"—a kind of professional hermaphrodites—most convenient for the purpose, because they were supposed to have sufficient knowledge to assist the midwife, without making a claim to be admitted among the scions of medicine. Thus it was that William Hunter, that Denman, that Merriman, were successively "men-midwives" to the Middlesex Hospital—a distinction which I believe still wreathes the brow of the obstetric physician to that institution. Man-midwife was the general term to include all obstetric practitioners of the masculine gender. In process of time, however, the public found out the truth, that the midwives knew little or nothing, and that it was essential for their security that the person in whom they confided should be educated: they acted, therefore, quite in opposition to their natural inclinations, and called in the aid of the physician or surgeon, not only in difficult, but in ordinary labours. The obstetric physician and the accoucheur superseded the midwife; the term "man-midwife" became obsolete, and is now only preserved in some institutions as

* This Lecture was delivered before the Medical Society of London, on March 23rd, 1853.

a kind of antiquarian curiosity. Midwives are now but rarely met with, except amongst the lowest classes; and even there, I know by experience, they are received with reluctance. The poor certainly employ them; but "'tis not their will, their poverty consents".

To what, then, are we to attribute this remarkable and most important change in the practice of midwifery? Why should the public silence their natural objections, and demand the accoucheur? Because they have learned, by bitter and most painful experience, the falsehood of the assertion that anybody may practise midwifery. They have found that, on this principle, the safety of all that is dearest to them has been too often entrusted to incompetent persons; and that education is just as essential to deliver a woman safely, as it is to cure a fever, or to cut off a leg. They require that the person who undertakes such a charge shall give proof that he possesses an obstetric education; and they accept the diploma which is presented to them from one or other of the medical corporations, as testimony of the fact.

But is this evidence adequate? Is the Licence of the College of Physicians, or the Diploma of the College of Surgeons, or the Licence of the Apothecaries' Society, a proof that the obstetric education of the possessor has been tested and approved of, in the same manner as his knowledge of medicine or surgery? There is but one answer to this question, and that is in the negative. The College of Physicians do not examine in midwifery: the College of Surgeons have only just now established a court for that purpose, the working of which has yet to be tested: the Apothecaries' Society alone have given the subject their attention. In their zeal to improve the education of those who come before them, they have laid down an excellent curriculum of study; and I believe that they examine candidates frequently upon their knowledge of obstetrics. *But they are not obliged to do so.* They are authorised to examine in medicine, but they may accept the definition of the College of Physicians, and say that midwifery is not medicine; consequently, they are *not obliged* to ask their candidate a single question in obstetrics; and they can, with a clear conscience, sign a certificate of competency, although the successful candidate may be thoroughly ignorant of that subject. I do not say that such is their practice; I believe that it is quite the reverse. I only assert that such may be at any time their rule, without any departure from their duty; and in this consists the objection.

At present, therefore, there is no certain test of competency to practise midwifery; the accoucheur is in a great degree self-taught, acquiring knowledge from lectures on the subject, and from attendance upon a few cases, but never having that stimulus which acts so powerfully on the pupil of medicine or surgery—the fear of his examination to entitle him to practise. Nevertheless, even with this imperfect education, he is more successful than the midwife, and proves trumpet-tongued the importance, nay, the necessity, of meeting the public want by insuring to them practitioners proved by examination competent to fulfil the duties required of them.

Why the Colleges at the head of our profession have been so tardy in the race of improvement—perhaps I should say, so blind to its necessity—it is not my purpose to inquire; more especially, because they form in this respect no exception to corporate bodies in general. If the question relate to reform in the legislature—reform in the law—improvement in our sanitary system, or in the working of the poor-law,—all corporate bodies, from the first assembly in the kingdom, from the House of Commons itself, down to the humblest board of poor-law guardians, however they may differ in other respects, are found unanimous on one point: *they never initiate a reform.* The public first feel the necessity of the change; then speak of it; and ultimately demand it. The corporation then yields to the pressure from without, with a good grace or a bad grace, as the case may be. The Colleges of Physicians and Surgeons would be much more remarkable if they were exceptions to this rule, than they are in so strictly following

it. It certainly should not excite surprise that, when midwifery was the property of midwives, these learned bodies should be reluctant to admit the man-midwife among them: but when this individual has totally disappeared; when we find, in the College of Physicians, gentlemen practising midwifery, whose attainments are fully equal to those of their *confrères*; when we meet, at the corner of every street, "Surgeon and Accoucheur", glittering in well-polished labels,—the time has arrived when that title must be a reality; when the public must be protected just as much from ignorant pretenders to midwifery, as they now are secured from unqualified practitioners in surgery.

If what has been stated be granted; if we admit that it is the business of those corporate bodies which regulate our profession, and are entrusted by the public with most responsible duties, to secure competent practitioners, whether in medicine, midwifery, or surgery, the question at once presents itself—To which of these bodies properly belongs the duty of qualifying the future practitioner in midwifery? This branch of practice is allied to medicine and to surgery; it has nothing whatever to do with *matéria medica* or pharmacy; yet, strange to say, the only corporate body which hitherto has endeavoured to fulfil this duty has been the Apothecaries' Society. The public are much indebted to them for their voluntary exertions; because, if it had not been for them, matters would be much worse now than they are. We must, however, always bear in mind that they are only volunteers: the onus of this responsibility does not properly belong to them. With whom, then, should it rest?

Let us first examine this question in reference to the College of Physicians. Midwifery and medicine are certainly allied to each other; and it is remarkable that nearly all our most distinguished obstetricians have been also physicians. A bond of union exists, sufficient to authorise that distinguished body to open its doors freely to practitioners in midwifery. Obstetric physicians have earned for themselves a sufficiently high reputation to reflect honour on their College, and to remove from those who may please to practise midwifery, the stigma which old and obsolete prejudice had fixed upon them. When the records of that College bear such names as Harvey, Hunter, Denman, and Haighton, to say nothing of living examples, I think that they need not be ashamed of the obstetric physician.

There is an undoubted alliance between medicine and midwifery; but it is not so intimate as to render it necessary that a physician must learn obstetrics in order to practise medicine. The duty of the College of Physicians seems to me to be limited to this—that if any of their body profess to practise midwifery, they should ascertain his fitness to do so, in order that the public, who do not understand distinctions very clearly, may not be deceived. I do not perceive that they are called upon to do more.

With regard to the College of Surgeons, it has been objected, that "midwifery is not surgery"; and I have been given to understand that examiners have felt that a candidate for their diploma might object to be examined on obstetrics; and yet, if he were qualified in other respects, they could not refuse it to him.

It is the more important to examine this proposition, because, if it were true, it must lead to this most serious evil: the public, who do not perceive this distinction, would be deceived when a surgeon practises midwifery on the strength of the diploma which he has received from that College. A little reflection will, however, convince any one that this is only a convenient sophism. If midwifery and surgery be not identical, I do not know what surgery is. Both differ from medicine in being arts: there is the art of midwifery, as well as the art of surgery. The skill consists in the readiness of manipulation, by which necessary operations may be successfully performed. The knowledge necessary for this purpose is similar; it requires just as careful a study of relations to remove a child from the womb, as it does to remove a stone from the bladder; and if ignorance in the latter case may lead to a false incision and death, in the former an error in delivery may rupture the vagina.

If it be said, that surgery means much more than merely skill in performing operations, that it implies a general knowledge of external diseases—a knowledge which is often as necessary to prevent an operation being performed, as to point out when it is really required—I would reply, that midwifery is just the same; it implies not alone the delivery by operation of the woman in labour, but also a perfect knowledge of all those disorders to which the womb is liable. If to surgery belong the treatment of ulcers on the leg, midwifery includes the management of ulcers of the neck of the womb—if I may be allowed to use such an expression. If the surgeon have a difficulty in deciding upon the propriety of removing a cancerous breast, the very same difficulty presents itself to the accoucheur in reference to carcinoma engaging the neck of the womb. In fact, the alliance is so intimate, as to lead to practical absurdities when we endeavour to separate them. What essential difference is there between the operation by which a child is torn piecemeal from the distorted pelvis, and that by which it is taken out of the womb opened through the abdomen? The former is a most difficult, a most disgusting, a most tedious operation, which may occupy hours in its performance; the latter is comparatively easy and rapid: both, however, are equally surgical operations. The accoucheur is permitted to mangle the child, if he will; but surgery claims her right to perform the Cæsarean section.

So, also, with respect to other operations—the removal of diseased ovaries—of polypi—of the inverted uterus—all these fall within the range of the accoucheur's practice; but they are essentially surgical diseases; and to treat them correctly, he must possess the operative skill of the surgeon. The obstetric physician who, as a physician, cannot use the knife, and must ask the surgeon's aid when it is required, may be embarrassed by these distinctions; but the surgeon-accoucheur can have no difficulty whatever. He is only following out the principle of his profession in performing any operation, from the smallest to the greatest, that may be required of him; and all operations connected with the womb, whether gravid or not, differ in no respect from operations in any other part of the body.

I hold, therefore, *that midwifery is a branch of surgery; and that every candidate for the diploma of a surgeon is bound to show that he is competent to practise it.*

So far, therefore, from a candidate having the right to refuse obstetric questions, his examiners, it appears to me, are bound to ascertain his competency in this respect.

I have the less difficulty in laying down this proposition, because it is not founded upon a mere abstract principle, which, though true in itself, is in opposition to experience. I assert, on the contrary, that the truth of the theory is proved by the practical working of it. The great majority of those who practise surgery also practise midwifery; and I affirm that they do so in right of their surgical diploma. If any man were to practise midwifery without such an authority; if he were to place "man-midwife" on his door, and expect practice, would he obtain it? Would the public place the same confidence in him as they do in the surgeon? Most decidedly they would not; and, therefore, the inference clearly is, that the diploma of the College of Surgeons is by them considered as the security that its possessor's knowledge of midwifery has been ascertained by those who gave it to him.

Now, if the list of the members of the College of Surgeons were examined, and the names of those who practise midwifery were separated from those who do not, what would be the proportion? I believe it would be found that the accoucheurs are more than ten to one. Those who are called "pure surgeons", who have been distilled from the impurities of obstetrics, form a very small minority—a most distinguished minority certainly, whose brilliancy sheds a lustre over the whole profession of surgery, but still a minority. Is it, then, to be said that the College of Surgeons is intended only to educate that small minority, and to leave the great majority of their diplomatists imperfectly qualified, incompetent to fulfil the duties which the public require of them? I do not think that any, the

most distinguished member of that body, would undertake to say that this alone is its duty. I am persuaded that, on reflection, they would acknowledge that the examination for their diploma should be perfect in itself; that it should be adapted to meet the obvious change which has taken place in surgical practice; and that care should be taken that the future surgeon-accoucheur be really what he calls himself.

I am the more earnest in urging this point, because I feel assured that the neglect of midwifery on the part of the College of Surgeons has been an error of judgment from ignorance, not from intention. The very fact that, in their new charter, they have sought for and have obtained powers to qualify practitioners in midwifery, is in itself a proof of their desire to improve this branch of practice. If, hitherto, they have felt a difficulty in examining candidates for their diploma upon midwifery, or if now they should err as to the best mode of carrying out their wishes for its improvement, the cause of this mistake may be very easily explained. The Council and the Court of Examiners are composed of gentlemen who do not practise midwifery; who are eminent as operating surgeons; who do not, who cannot, know what midwifery is, nor what it requires; consequently, they fall into the very natural error of leaving "midwifery to midwives". Their idea of obstetrics is something like Falstaff's notion of honour—

"It hath no skill in surgery, therefore they'll none of it."

The time has now arrived to correct this mistake; and this, I am persuaded, will soon be done, because the College of Surgeons must perceive the importance of adapting their examinations so as to meet the wants of the public.

If I have satisfied you that the duty of providing not only qualified surgeons, but qualified accoucheurs, rests with the College of Surgeons, it remains for me to point out to you and to them the errors that have been committed, and the effects that must spring out of their present regulations for an obstetric qualification.

An Obstetric Board of Examiners has been appointed, of a most efficient character. The College could not have been more happy in their selection, nor could they have abler assistants to carry out any plan for the improvement of midwifery than these gentlemen. No objection, therefore, can be raised against the Board of Examiners: the error lies in the "Regulations of the Council respecting the Professional Education of Candidates for the Certificate of Qualification in Midwifery". These regulations have been founded upon a false principle—a voluntary principle; and, consequently, there is a danger that they will have an effect precisely the reverse of what is intended.

First let us consider the effect upon the future candidate for the surgical diploma. This gentleman knows perfectly well that he will not be examined in midwifery; the fact that a board has been especially appointed for that purpose, convinces him of this. He is not obliged to go before the board; consequently, he takes very little pains to improve himself on the subject of midwifery. This gentleman may be an excellent anatomist; he may be able to display great acumen in discussing the merits of curing aneurism by compression; he may even have obtained the highest prize the College can give; but he knows nothing whatever about the mode of turning the child, of using obstetric instruments, or even of removing a placenta. This neglect is further encouraged by the very small amount of obstetric knowledge which is required by the curriculum of the College. He need only attend a single course of lectures on midwifery. This course must be delivered in the summer session; and, consequently, cannot exceed sixty lectures. Now, all the teachers of midwifery, in every school in London, have been unanimous in declaring that they could not give a complete course of midwifery in sixty lessons. The College of Surgeons have been informed of this by deputation; yet no change has been made. Nay, even in their new regulations for the licentiate in midwifery, they still adhere to one short summer course of sixty lectures,

which they have been already informed is totally inadequate for the purpose.

At present, therefore, a candidate for the surgical diploma is not examined in midwifery. He is only required to attend this short and necessarily most imperfect course of lectures; and, therefore, may leave the College, even with credit, his brows crowned with laurels, yet totally unfit for the duties of an accoucheur.

Let us follow this gentleman in his entrance upon his career of practice. He selects a neighbourhood which seems to offer a favourable opportunity for his wishes; he has "surgeon-accoucheur" on a conspicuous label, or perhaps simply "surgeon", but beside it the equally significant "night bell". No doubt he is looking out for fractures or dislocations; for opportunities to tie or compress the femoral artery; he is anxious to cut for the stone; or at least to perform amputation. No such opportunities, however, present themselves. There is always in the same locality some surgeon of established reputation, to whom the public fly in such difficulties. The young aspirant is left to himself, so far as pure surgery is concerned. He has, however, acquired some distinction as a student; he has also a good general education and address. Those most interested in him are very anxious to obtain for him some practice, and a lady prevails upon her friend to permit him to attend her in her next confinement. "He has obtained his diploma at the College of Surgeons with the highest honour; and, therefore, must be a safe accoucheur." This gentleman succeeds, or rather nature succeeds for him. He obtains thereby an introduction to the family, and makes his *début* in practice. But that practice is midwifery, not surgery; and thus the very first duty which he is called upon to perform is precisely that about which he knows the least.

If, however, this picture were reversed; if it were a labour of difficulty—of danger; if the life of a child—perhaps a first-born, most anxiously looked for—or if the still more important life of a mother be the sacrifice, on whom falls the responsibility of this most unpardonable ignorance? Is it any answer to say, that the public must know that midwifery is not surgery; and that if they employ a surgeon, they do so on their own responsibility? The public know nothing of the kind; they make no such distinctions; and they employ a surgeon, because they believe that he is a surgeon in all its branches, and in every sense of the term.

I trust, therefore, that the College will perceive the necessity of correcting this mistake; of improving their curriculum; and recognize the importance of requiring that all candidates who present themselves for a surgical diploma shall have given proof to the Obstetric Board that they are competent to practise midwifery.

This knowledge cannot be an incumbrance to the minority who would confine their attention to pure surgery; while to the great majority, who purpose taking obstetric practice, it is essential. I feel it the more my duty to press this necessity upon the attention of the College of Surgeons, because the position which I have the honour to hold, as a teacher of midwifery, gives me, as well as my colleagues, the opportunity of knowing how indifferent pupils are with regard to anything that concerns midwifery. Anatomy, physiology, the theatre where they witness the great operations in surgery—operations which they may never be called upon to perform—the dead-room, and the microscope, all receive their best attention; but that knowledge which is necessary to fulfil the very first duty that may be required of them in their entrance on practice; that which may be their only means of obtaining practice, holds no place in their estimation; nor will it do so until it is forced upon their attention by more stringent regulations than at present exist.

Another effect which springs from the false principle upon which the duties of the Obstetric Board are established, is that an injustice is committed against the student who obtains every qualification which will really make him what he professes himself to be—a surgeon-accoucheur. He has obtained his diploma to practise surgery, and his license to practise midwifery; but whether his future opponent may

do so is quite a matter of taste. Let us suppose this rival to be a gentleman not particularly desirous to burden his mind with too many duties or too many examinations. He will do nothing which he is not obliged to do; consequently he neglects obstetrics altogether, and is perfectly satisfied if, by the aid of a grinder, he is triturated sufficiently fine to be sifted through the surgical examination. No doubt he thinks it a great blessing that he has only one examination to go through, and laughs at his competitor for taking so much pains to go through another which is not required of him. He obtains his diploma from the College; but the moment it is in his possession, he will not hesitate to practise midwifery on the strength of it. The document will be, perhaps, displayed in a gilt frame, to give the public confidence, and to prove to them that he is qualified in every respect. There is no certainty that his incapacity will be exposed, because Nature is his hand-maid. Sooner or later, however, the moment may come when his knowledge is put to the test; a difficulty may suddenly arise to which he is unequal; and a life may be sacrificed to his incompetency. But is it just to allow the prospects of his more industrious competitor to depend upon such a contingency? Is the inattentive and incompetent student to make the practice of midwifery, because it is easy, a means of accomplishing what he never could hope to do without its aid? Is he thus to defeat his better educated rival? And yet, according to the present regulations, this may be done. An evil greater even than this results from them, because a serious injury is also committed against the public.

The diligent student is not satisfied unless he has every qualification necessary to his practice. He will go before the Obstetric Board. Even members of the College, who have already obtained their surgical diploma, are now hastening to it. There is no doubt that those, who are devoted to their profession, will embrace every opportunity of giving proofs of their intelligence; consequently, they avail themselves of this examination. But the public are in no danger from them; they are injured by the idle and the ignorant: and there is no branch of medical science which shelters these defects more than midwifery; there is none which requires more protection.

So far, therefore, as the student in surgery is concerned, an obstetric examination which is voluntary is mischievous, because an encouragement is given to the most unsafe class—to the careless—to neglect midwifery altogether; and a serious injury is done to the industrious student when he finds himself opposed in practice, even successfully, by this very idler, who, like him, practises midwifery, and has had the good fortune to escape exposure. The public only know both equally as surgeons.

This examination, however, is not only voluntary to the student in surgery, but is open to the whole world. The chemist or the greengrocer, the laundress, or any other old woman, may go up to be examined. It is true that the curriculum required, although not very severe, would be quite too much for these sagacious individuals; neither do I think that they would so easily escape the present Board of Examiners. But where is the security that such will always be the case? Curricula are frequently altered; examiners are changed; and I think that I can appeal to experience how unequal the examinations at the College have been, sometimes enabling candidates to pass with the utmost facility, and again becoming a most respectable test. Now, it is just possible that at some future time it may be argued, that midwifery is practised by a great many old women, and other similar characters. They seem quite competent for the purpose, but are manifestly unequal to the present regulations. "It is a pity not to encourage them to come forward and prove their knowledge"; and consequently it would be most advisable to suit the curriculum and examination to their comprehensions. Such may be the argument for admitting these, and for dubbing, by the authority of the College, some future Mrs. Gamp a "Licentiate in Midwifery".

Another, and a far more important objection—

while the former is prospective, this is immediate—is that which has been already very strongly urged. A new and much easier course of study is laid down for the obstetric examination than for the diploma of the College; hence it must lead to the constitution of a new and inferior class of practitioners. The student may obtain from the Society of Apothecaries his license to practise medicine and pharmacy. He gains a license to practise midwifery from the College of Surgeons. He wants nothing more. He calls himself a general practitioner, or perhaps a "Surgeon-Accoucheur"; but is quite content to send all the broken bones, all the aneurisms, all the lithotomy cases, to some Teale, or Hodgson, or Fergusson, in his neighbourhood. He confines himself to a very lucrative general practice. In order to accomplish this, he can finish his education in three years (the surgical student requires four); he can exhibit certificates of having attended within that time the practice of a medical and surgical hospital, and lectures on the practice of physic and practice of surgery; he can prove to the public that he has attended to medicine and surgery just as much as any surgeon, and knows midwifery besides, which they know nothing about. If this be not an argument in favour of the licentiate in midwifery, that will tell in due time with powerful effect, I should be greatly surprised.

In fact, by the present regulations, students are at once separated into two classes; into the future surgeons, who know nothing in the world of midwifery; and the future accoucheurs, who are equally ignorant of pure surgery. Now, it would be a curious question to determine which of these classes would predominate; nor do I think there would be much difficulty in arriving at a correct conclusion. We need only examine the curriculum appointed for each, to decide.

The College requires that the surgical student be engaged four years in his professional education. He must attend a surgical hospital for three years, and two winter courses of lectures on the principles and practice of surgery; a medical hospital for one year, and one course of lectures on the principles and practice of medicine. Besides this, anatomy, physiology, demonstrations, and dissections, must occupy his attention for three winter and two summer sessions. *Materia medica* and midwifery are disposed of in one summer session, and chemistry in one winter session.

The candidate for the certificate of qualification in midwifery can complete his education in three years; his anatomy and physiology may be finished in two winters; he has one course of lectures on surgery, and one on medicine to attend; a surgical hospital for one year; and a medical hospital for one year. He need not trouble himself about *materia medica* or chemistry; and in midwifery, the leading subject of his study, he is not asked to attend more than one short course of instruction. He is certainly obliged to attend thirty labours; but it is not said *when or how*; and, consequently, he finds no difficulty in this. Many students come up from the country, having attended thirty, forty, or even fifty labours, before they have attended a single lecture on midwifery. The cases are attended haphazard, and the education is that of the midwife. They learn nothing but patience and to support the perineum.

It is only necessary to compare these curricula, to determine which the majority of the students will select. They have only to decide whether they will study surgery in its higher branches, so as to become skilful operators, or content themselves with a more modest education for a quiet, comfortable, money-making general practice. I fear that they might be inclined rather to the latter than the former course; that the licentiates in midwifery would greatly exceed the licentiates in surgery, and the College become rather a College of Accoucheurs than a College of Surgeons. I do not think that the Council could have contrived a more ingenious method of relieving themselves from the perhaps too onerous duties of the Examining Board, than by establishing licentiates in midwifery.

The objections to this clause,* then, may be briefly

summed up in this—that it is founded upon a false principle. It assumes a distinction between midwifery and surgery which does not exist: there is no essential difference between them. Hence, if *any one* present himself to the College of Surgeons for examination, he demands an authority to practise as a surgeon. It is the duty of the College to ascertain that he is a surgeon, not only as regards the practice of midwifery, but every other branch connected with it, just in the same manner as it is their duty to know whether the candidate for a surgical diploma is competent to practise midwifery. There is no necessity, therefore, for framing an easy curriculum for the former, and a more difficult one for the latter. The curriculum should be uniform, but so adapted as to meet the requirements of the obstetric examination.

I press this point the more decidedly, because nothing is so easy as to effect this adaptation. The College requires that the student be engaged four years in the acquirement of professional knowledge. Let them only specify what is to be done in each year, and they will find an abundance of time for a perfect curriculum of education. All that is required by the Obstetric Board, by the Society of Apothecaries, and by the College of Surgeons, can be accomplished within that time. The pupil may, if he please, pass each examination in succession; and it is only necessary for the College to provide that he receive, at the same time, his license to practise midwifery and his diploma for surgery.

I have now, I fear at the risk of exhausting your patience, endeavoured to demonstrate the following propositions.

1. That a great sacrifice of human life may be the consequence of neglecting the education of the accoucheur; and that it is not true that, because parturition is a natural process, any one may practise midwifery.
2. That midwifery is essentially a branch of surgery, and is constantly practised in alliance with it. The title "Surgeon-Accoucheur" is universal.
3. That it becomes the duty of the College of Surgeons to ascertain that *all* those who receive from them authority to practise surgery, are also competent to practise midwifery.
4. That a certificate of qualification to practise midwifery should not be given to any student, until it has been ascertained that he is also qualified to practise surgery.
5. That there is no occasion for an easy course of study for midwifery and a more difficult one for surgery; and where no necessity exists, the distinction leads to the establishment of an inferior class of practitioners, which would be most injurious to diligent students, to the profession, and to the public.

It only remains for me to prove by facts what I have stated to be the probable results of neglect of the education of the accoucheur, and to convince you what ignorance may do in the practice of midwifery. Time will only permit to quote extreme cases; which however, will be sufficient for the *a fortiori* argument which they illustrate.

On August 15th, 1846, a coroner's inquest was held at Towcester, to inquire into the circumstances attending the death of Anne Smith. "It appeared from the evidence of the witnesses, that the woman was taken in labour of her first child about the middle of the day on Friday. Mr. G., (M.R.C.S.Eng.) was sent for, and arrived in about an hour. He told them she was going on well, and that he would return in a short time: he did so in about three quarters of an hour, and remained within call (but not in the patient's room). He was several times requested to go up 'to help the woman', but did not, until immediately before the birth

required to produce the following certificates:—Of being 21 years of age—of having been engaged for three years in the acquirement of professional knowledge—of having studied practical pharmacy for six months—of having attended lectures on anatomy and physiology, with demonstrations and dissections, during two winter sessions—of having attended one course of lectures on the practice of surgery—of having attended the medical practice of a hospital during twelve months—of having attended the surgical practice of a recognized hospital during twelve months—of having attended one course of lectures on Midwifery and the Diseases of Women and Children—of having personally conducted thirty labours."

* "All other persons [except qualified surgeons and physicians] will be

of the child, which took place about six o'clock. He tied and cut the cord in the usual manner; and shortly afterwards in making traction broke it off at its attachment to the placenta: a gush of blood followed, but the nurse could not speak with confidence as to the quantity. Mr. G. then gave the patient a dose of tincture of opium, telling her friends there was something more to come, and left promising to return between eight and nine o'clock. A short time after Mr. G. left, the patient became very faint; and one of the women noticed a pool of blood on the floor under the bed. A message was dispatched for Mr. Collier, surgeon, who attended without delay, and found the patient exsanguineous, and in a state of syncope. He immediately removed the placenta, and ordered wine and brandy to be administered. The hæmorrhage ceased after the extraction of the placenta. Mr. Collier sent home for ammonia and other stimulants; but death took place before the return of the messenger.*

This M.R.C.S.E. not only by violence broke off the funis, but did not even know the amount of danger to which he exposed his patient. Her life was sacrificed to his ignorance of midwifery.

In March 1845, a coroner's inquest was held in Norfolk. Considerable excitement prevailed in consequence of the death of a married woman named Jane Mary Lovett; the melancholy event being attributed to grossly ignorant treatment on the part of the medical man who attended her: and so it was, as will be seen. The woman was safely delivered of a female child, without any more difficulty than on former occasions. Ann Cassel, a midwife, was examined and gave the following evidence. She stated "the after-birth did not come. Mr. Gaches tried to get at it. Mrs. Lovett (the patient), said to him 'I cannot stand it'. I made answer and said, 'It must be got'. I then asked Mr. Gaches if he did not want further help. He said he did not think any doctor could do more than he was doing for her. I said to him 'Let her rest a little time'. The poor woman exclaimed 'Let me lie and die, don't let me be meddled with any more'. Mr. Gaches at length removed a round substance, unlike anything the midwife had seen before, which Mr. Gaches had taken away with him. After Mr. Gaches left the woman, I said to her husband, 'For God's sake go for Mr. Gaches, I think your wife is dying'. The husband went, and he (Mr. G.), came directly; but the woman died before he arrived."† The substance which the midwife never saw before, proved on the *post mortem* examination to be the inverted uterus, which Mr. G. actually tore out of this unfortunate woman's body, and carried home for a more careful examination.

On August 5, 1848, at the Staffordshire Summer Assizes, William Harding Flint, of Longnor, described in the *Provincial Medical Directory* as M.R.C.S.E., (which, however, was questioned,) was accused of killing and slaying Elizabeth Riley, at Sheen, in Staffordshire.

"It appears that Mrs. Riley, the wife of a respectable farmer at High Sheen in Staffordshire, was taken in labour, and sent for the accused party, who arrived between two and three o'clock on the morning of March 29. It appears that he made an examination, and then went to bed, where he remained until between seven and eight o'clock. On making an examination at this time, he is said to have pronounced it a preternatural presentation, and to have sent the husband to Longnor for his instruments. He appears to have been impressed with the necessity of turning; and he performed some manipulations, during which he told the women about him that he had turned."‡ The manipulations were as follows. Sarah Mellon, a midwife, stated "He was pulling a hand and foot", and asked Sarah (the midwife), to help him. He was asked if he wanted more help; but he said "I have brought one, and shall have another in four minutes, nay two; I shall want no more help". The woman was, however, so obviously dying, that the friends insisted, contrary to his wishes, lest he should

expose his patient, (or rather himself,) on throwing back the clothes, and seeing what was the matter.

Elizabeth Hirobin, a neighbour of the deceased woman, being ordered to state what she really saw, shaking her head and holding up her hands, said "Oh such a sight!! I saw a leg and a foot, an arm and a hand, and something like intestines hanging out nearly a foot; but I walked away to another part of the room: I could not stay". The midwife was curious to know about the child he professed to take away, and she said "Dr. Flint, tell me one thing; you said you brought forth a child and put it away. It is no such thing; you have not". Dr. Flint replied, "What was that substance then?" The midwife very properly retorts, "You are a doctor and ought to know better than me; but if you don't know, I'll tell you to the best of my knowledge. I never saw anything like it in my life; but I think it was part of her womb and her bowel-skin".* This unfortunate woman died in ten minutes afterwards. A pen-knife was found lying on the bed; so that this gentleman—calling himself a surgeon—in attempting to turn a child, brings down a foot; but he is so thoroughly ignorant of midwifery that he pulls at the arm and foot together; the uterus is ruptured, and the intestines descend. He mistakes the coil of intestines for a child; and to assist the delivery evidently cuts the bowel across with the pen-knife, and removes it; saying (very truly) that more was to come. A life is thus sacrificed to the grossest ignorance.

I have, in these details, confined your attention to those instances, and only a few of them, which have come before a public jury; but that such are not the only evidences of malapraxis, I shall quote one from many proofs that are noted in the secret records of practice. It is only by accident that such facts become known; and I am persuaded, that if we had all the mismanaged cases, all the deaths of children and of mothers from mere ignorance, that fall under the observation of distinguished practitioners who are consulted in such cases, they would fill a volume. One of these eminent men was the late Dr. John Greene Crosse, of Norwich, who relates the following extraordinary case. His words are these:—

"The most extraordinary and anomalous case which I have hitherto met with in the whole course of my practice is the following. Some of the circumstances appear so monstrous, that credit would not be given to the narrator, except by those to whom he was known, by the station which he held, or the correct statements which he had offered to the public on other subjects. Yet, were I to publish this case, I could scarcely refer by name to other parties—fellow-witnesses of the dissection—for delicate reasons that must occur to every one." Such is the reason why this case remained quietly in Dr. Crosse's case-book until after his death, when it was published in Dr. Copeman's collection. He proceeds: "I was called up at two o'clock this morning by Mr. —, to go to H., a distance of seven miles, to a case of midwifery, attended by some unaccountable circumstances; and though the woman was dead, the three surgeons, who had been with her, wished me to go for their satisfaction, as they did not like to quit the house, leaving the woman undelivered, unless they could explain what happened. They, moreover, wished to inspect the body, which they feared would not be allowed if they quitted the house." The woman, aged 40, had borne seven children, and thought herself again pregnant and near her full time. She was feeble and jaundiced. Labour commenced the day before Dr. Crosse was sent for. Mr. H., who was engaged to attend the patient, when he arrived, and made an examination, found "a soft tumour in the vagina, reaching nearly to the external labia, which he supposed was the liquor amnii distending the membranes. Soon afterwards, Mr. — (another surgeon, who had been sent for on its being found that Mr. H. was from home), arrived, and on examining, thought the placenta was presenting, and that it was a case for turning. Mr. H. ruptured the presenting part, or the part low in the vagina,

* *Lancet*, 1846, vol. ii, p. 302.

† *Lancet*, 1845, vol. i, p. 341.

‡ *Lancet*, 1848, vol. ii, p. 160.

* *Lancet*, p. 161.

expecting the waters to escape; but only a little blood flowed. He brought away several portions of a solid substance, not unlike placenta after being well washed in water." Having acted thus far under the impression that the case was a placental presentation, the same belief was entertained by both gentlemen present, and turning was agreed upon. "So Mr. H., having removed his coat and bared his arm, introduced it through the mass into the vagina; and believing he must reach the uterus, could not explain why he did not distinctly feel the child, but thought, at one time, he got the foot of the child: he, however, could not retain it; he got hold of something else, and no doubt used some force with his hand. On withdrawing his hand, he brought away a firm, whitish substance, which appeared like a bean. Mr. H. likened it to a bile stone. Mr. — next introduced his hand; he could not detect a fœtus. He, however, felt the spine; and said he could feel a bag of such stones as the one brought away by his more active and more experienced companion. Neither of them suspected that the hand had been introduced anywhere but into the uterus. Numerous portions of the whitish soft mass, resembling, by candle-light, well washed placenta, were brought away. The woman died half an hour after these attempts, though there had not been much loss of blood: there had been a gradual loss, but no rapid flooding."

The third gentleman arrived (like Dr. Crosse) after the woman's death had taken place; and in the presence of the four, a *post mortem* inspection was made. "The corpse was lying on the bed doubled up, in the usual position for examining during labour, with her clothes on. I (Dr. Crosse) introduced my hand into the vagina, and felt lacerated parts, but could not distinguish fœtus or os uteri. On withdrawing the hand, portions of a substance twice as big as a walnut escaped, of precisely the same appearance and consistence as what had been removed during life. Placing the corpse on the back, I made an incision in the course of the linea alba into the abdomen, extending from the sternum to the pubes; and as soon as the peritoneal cavity was opened I discovered a quantity of coagulated blood, as much as eight or ten ounces, spread in a thin layer over the intestines. The uterus immediately presented itself: it contained an acephalous fœtus, plump and full grown in its limbs and body, and apparently not less than eight months old. The placenta was cut through. The membranes were entire; the os uteri was open to the extent of a shilling; but it had never been dilated nor meddled with in all the examinations which had taken place during the supposed labour; for the uterus lay high above the pubes and forwards, pressing immediately behind the anterior parietes of the abdomen. Pulling aside the uterus, and also the intestines, so as to examine the cavity of the pelvis, I found the whole cavity filled with a morbid mass. Through the most compact part of this morbid mass, in the centre of the pelvis, anterior to the rectum, was a lacerated opening leading into the vagina; and it was clear that the hand of the accoucheur had made its way through this passage into the peritoneum. One inexplicable circumstance was now explained: the gall bladder was ruptured at its larger end; several small white biliary calculi were amongst the viscera near it, and numerous others in the cavity; one big as a nut, others varying in size from a pea to a bean. Altogether I collected fifty-six of these calculi; not including two or three removed per vaginam during life."* Such a case as this, where the hand was forced through a morbid mass—through the vagina into the peritoneum—up to the gall-bladder—with the result of bursting it and delivering gall-stones, requires no comment.

I have now, sir, to apologize for having so long occupied your attention. I can only plead the vast importance of my subject. I have brought before you a branch of medical science which embraces within the range of its studies the physiology of generation, the laws of our organization,

the development of tissues, the pathology of the ovum (as yet among the arcana of medical science), and the pathology of the uterus: a branch of practice which includes not merely the phenomena of parturition and the management of labour, but also the important but as yet imperfectly understood class of diseases which affect the female generative organs, as well as the disorders of infancy and childhood, scarcely better known. I trust that it will be admitted that midwifery is worthy to be considered one of the medical sciences, and that in a practical point of view it equals in importance general medicine and surgery. I have endeavoured to prove how completely it has been neglected, and to demonstrate the melancholy sacrifice of human life that may be, that has been, the consequence. When such is the case, when an absolute necessity exists for its improvement and protection, I cannot forbear raising my voice against the present system of obstetric education, convinced that it leads to its still further degradation.

I trust that I may be pardoned for so great a trespass on your attention, in my effort to prove the danger to which the public must be exposed, when an obstetric education is totally neglected: and in my desire to show that the very attempt to supply this deficiency will produce precisely opposite results, give encouragement to presumptuous ignorance, and thus become only a delusion and a snare.

Henrietta Street, Cavendish Square, April 1853.

THE RESULTS OF RE-VACCINATION, AS OBSERVED IN 257 CASES.

By W. BIRD HERAPATH, M.D., Surgeon to St. Peter's Hospital, Bristol, etc.

It may be interesting to the readers of the ASSOCIATION MEDICAL JOURNAL, and to the profession generally, if I communicate the results of re-vaccinating the inmates of two large public schools, with which I am professionally connected—the Red Maids' School, and Queen Elizabeth's Hospital. The former establishment contained, at the time of the experiment, 101 girls, and the latter, 158 boys.

The occasion of this extensive re-vaccination was the occurrence of small-pox. One case having shown itself in each establishment, it was thought desirable to prevent the extension of the disease by isolating the infected children, and to simultaneously destroy or remove the pabulum of the disease, by at once submitting the whole of the inmates to the process of vaccination.

The success of the experiment was perfect: not a single fresh case occurred. The two patients suffering from the disease passed through the stages safely and satisfactorily, without a single bad symptom, although they were both thickly covered with pustules. However, it is but fair to state that from the modified form of the pustules, the slightness of the accessory and secondary fever, and the subsequent progress of the cases, there is no doubt that they were cases of varioloid, rather than of variola: the disease in the girl being varicella umbilicalis; and in the boy varicella coniformis, two varieties of varioloid, described by Erasmus Wilson in his work on *Skin Diseases*. Both these children had been vaccinated previous to their admission into the school; and their arms bore the evidence of two distinctly foveolated moderately large cicatrices.

It is a wise regulation of the trustees, that evidence of vaccination, or of having had small-pox, shall be shown by each candidate for admission to these excellent institutions before their election: and it is part of my duty, as their medical officer, to examine each applicant and to report thereon; and to exclude all who do not satisfactorily prove to have had the small-pox or to have been effectually vaccinated. Of the two hundred and fifty-nine inmates, only one admitted of any doubt on this point. This one case was reported to have been vaccinated, and was admitted by my predecessor; but upon re-examination, at the date of

* Copeman's "Cases of Midwifery". By the late John Green Crosse, M.D. pp. 49-52.

this experiment, no mark or cicatrix was apparent. Seventeen had had small-pox without previous vaccination; and twelve are reported to have had small-pox subsequently to vaccination.

Of the two hundred and forty who had been vaccinated, there were three cases in whom four cicatrices were apparent; twenty-one in whom three cicatrices, more

or less perfect, were present; one hundred and sixty-three had two cicatrices; and in fifty-two one vaccine mark only was perceptible.

These cases have been arranged in a tabular form, more clearly showing these appearances, and more minutely describing the characters of the cicatrices and the results of re-vaccination. (Vide Table I.)

With respect to the ages of the patients, it should be premised that they all ranged between eight and seventeen and a half years; the one being the age at which the

girls are admissible to the school; the other at which they are discharged. The boys are admitted at from eight to ten years, and go out at from fourteen to fifteen years of age.

The following table shews their ages more clearly :—

2 cases from 8 to 9 years.

259 giving an average age of 12·91 years.

RE-VACCINATION. The lymph employed was obtained from the arms of four healthy children, who, of course, had been previously submitted successfully to the operation. It was taken on ivory points at the eighth day of the vesicle, and before the areola had attained its full development; it was, therefore, in its most active state. In all instances, two punctures were made in the left arm; or at least each spot was slightly scarified by the point of a lancet again and again at right angles. This is certainly the most successful mode of vaccination, when employing lymph dried on points.

The first effect of re-vaccination was the appearance of a vivid efflorescence, gradually extending from the second to the fifth day. This then subsided without the formation of a vesicle, if the system were still efficiently protected by the previous vaccination. Those cases on the eighth day merely appeared as slight, very minute dry scabs, just serving to mark the spots where the incisions had been made. In about fifty-six cases, or 21·4 per cent., this was apparent in both punctures. In seventy-three cases, or about 28·8 per cent., this was the effect in only one point. These have, in the accompanying tables, been registered respectively as failures in two points, and failures in one point.

In thirty-six cases, however, the effects proceeded to a step further. On the eighth day a conical elevated and inflamed base was formed, having an areola more or less

irregular in figure, with a minute vesicle on the apex of the cone; but this vesicle was neither umbilicated nor of any determinate form. These cases did not advance, but either gradually subsided, or at most dried up to a slight and imperfect crust, which invariably fell off at an early date. These were all registered as "abortive vesicles"; and were about 14·0077 per cent.

In seventeen of the cases the vesicles were larger, but had a more or less irregular outline, somewhat oval, with borders ragged from the existence of numerous smaller vesicles at the edges of the primary vesicle. These, probably, arose from the little patients having scratched and more or less rubbed and injured the vaccine vesicle during its formation. These generally became purulent, and dried at the same dates with the next and more perfect class, and the crusts endured the usual period; but as they were not perfect, they were excluded from the correct enumeration. This class is arranged under the head of irregular vesicles; and amounts to 6·61 per cent.

In seventy cases a single perfect vesicle, with a good and more or less evident areola, formed "the real pearl upon the rose". Most of these appeared as usual upon the eighth day; some were later, and not formed until the ninth or tenth day; but these were not a dozen in number. This class, therefore, contained about 27·23 per cent. There were also eighty-eight cases, in which two perfect vesicles were formed on the same arm. This class contained 34·63 per cent. The two last classes went through their subsequent stages of maturation, pustulation, desiccation, and desquamation, or rather dehiscence of the crust, in the usual way, and at the regular periods, as if they had not previously been submitted to vaccination. The perfectly successful class may therefore be said to include both the seventy cases of single vesicles, and the eighty-eight cases of double vesicles; and would therefore amount to 61·96 per cent.

In these per centages, all cases have been taken indiscriminately; they are the general results of the whole experiment. But upon analysing the facts a little more rigorously, some curious results become apparent.

TABLE II.—Results of Re-Vaccination, as shewn by preceding Tabulated Experiments.

Cases.		Cases.	Description.	Re-Vaccinated.	Total failures in two points.	Partial failures.			Successful cases.		
						Falling in a single point.	Vesicles only slight and abortive.	Vesicles irregular.	Double perfect vesicles.	Single perfect vesicles.	Total double and single vesicles.
242	Vaccinated	230	Vaccination	230	51*	68	32	15	75	64	139
		12	Varioloid and Variola 2 in bed	10	1		2	2	6	2	8
17	Un-Vaccinated	17	Variola	17	4	5	2		7	4	11
259		259		257	56	73	36	17	88	70	158

* Case 11, vaccinated four months ago; 132, two years and five months ago; 214, six years and four months ago, did not take at all.

In the first place, seventeen cases who had had small-pox were experimented upon; these had not been previously vaccinated, but all more or less presented evidence of having suffered from this ruthless destroyer of human beauty.

(a.) Of these seventeen cases, there were four of perfect failures in both points = 23·53 per cent.

(b.) Of these seventeen cases, there were five in whom single points did not produce vesicles = 29·4 per cent.

(c.) Of these seventeen cases, there were only two in whom the vesicles were "abortive" = 11·765 per cent.

(d.) There were no irregular vesicles.

(e.) There were seven cases in whom double vesicles resulted = 41·2 per cent.

(f.) There were four cases in whom a single vesicle, perfect in shape, etc., made its appearance = 23·53 per cent.

(g.) The two last classes together make a per centage of successful vaccination after small-pox of 64·73.

There is a class of ten cases, in whom vaccination had been successfully performed, as is shown by decided cicatrices. Four of these have one mark; five have two cicatrices; and one case has even three cicatrices. The evidence of small-pox is also pretty strong in all of them: in some, however, the marks are only slight; but these were decided to have had the small-pox, only after a rigorous examination of the parents as to the age at which they had it, and the effects of the same epidemic upon others of their children who had it at the same time.

- (a.) There was one double failure = 10 per cent.
 (b.) There was no single point failure.
 (c.) There were two cases of abortive vesicles = 20 per cent.
 (d.) There was one case of irregular vesicles = 10 per cent.
 (e.) There were six cases of double and perfect vesicles 60 per cent.

(f.) There were two of single perfect vesicles = 20 per cent.
 Having disposed of the influence which the two minor classes, variola and varioloid (B and C, Table I), have upon vaccination, we may ask whether the distinct evidence of previously successful vaccination has any influence in preventing the reabsorption and constitutional effects of vaccine virus. For this purpose Table III has been compiled.

TABLE III.—*Effect of previous Vaccination upon the present Results, as estimated by the Distinctness or Indistinctness of the Cicatrices.*

CLASS I. CICATRICES DISTINCT.

	No. of cicatrices.	Cases.	Failures in double points. a	Imperfectly successful.			Successful.		Total successful cases. g
				Failing in single points. b	Vesicles abortive. c	Vesicles irregular. d	Double vesicles. e	Single vesicles. f	
a	1	30	8	9	4	2	5	10	15
b	2	112	25	31	16	6	45	24	69
c	3	19	5	5	3	3	4	10	14
d	4	2		1			1	1	2
Total.....163			38	46	23	11	55	45	100
Per cent.			23.313	28.22	14.11	6.742	33.742	27.60	61.350

CLASS II. CICATRICES FAINT.

a	1	18	4	4	3	1	5	4	9
b	2	46	9	17	6	5	13	12	25
c	3	1	0				1		1
d	4	1		1				1	1
			66	13	22	9	6	19	17
			19.70	33.33	13.6	9.00	28.8	25.75	54.54

From this it appears, that upon dividing the vaccine cicatrices into two classes—one distinct and well marked, the other faint and slight—the following results are obtained.

There were one hundred and sixty-three cases in the first class. These cicatrices were in everything all that could be wished as evidence of perfect vaccination. The per centage of entire failures amounted to 23.313.

Comparing this with the second class, in which the cicatrices are slight and indistinct, we find that the failures are about 19.79 per cent. This would appear as if successful and perfect previous vaccination exerted a slightly in-

creased preservative influence over the system, thus rendering its subsequent impregnation more difficult.

However, this view does not appear to be entirely borne out; for upon looking to the column g, or that of total success, we see that there is a per centage of 61.35 for the first class, and 54.54 only for the second. The other columns shew a remarkably close parallel between the two classes, and justify us in coming to the conclusion that the distinctness or indistinctness of the vaccine cicatrix has but little, if anything, to do with the question at issue. We will now examine a careful *resumé* of all the previous per centage results, as collated in Table IV.

TABLE IV.—*Per-Centage Results of the foregoing Experiments on Re-Vaccination.*

	Total Failures. a Per cent.	Imperfectly successful.			Successful in every respect.		Total successful cases. g Per cent.
		Failures in single points. b Per cent.	Vesicles abortive. c Per cent.	Vesicles irregular. d Per cent.	Double vesicles. e Per cent.	Single vesicles. f Per cent.	
Previous Re-Vaccination, 230 Cases	22.174	29.565	15.21	6.521	32.60	27.826	60.435
(a.) Cicatrices distinct, 163	23.313	28.220	14.11	6.742	33.742	27.60	61.350
(b.) Cicatrices faint, 66	19.700	33.33	13.6	9.09	28.800	25.75	54.54
Variola and Varioloid after Vaccination, 10 Cases	10.000	0	20.00	10.000	60.00	20.00	60.00
Variola without Vaccination, 17 Cases	23.53	29.4	11.765	0	41.20	23.53	64.72
Average results of the whole 257 Cases	21.40	28.8	14.0077	6.61	34.63	27.39	59.49

One fact of importance may be noticed in this place: I refer to Table II. It there appears in a note that three cases—No. 11, vaccinated four months ago; No. 132, vaccinated two and a half years ago; and No. 214, vaccinated six years and four months ago—did not again become sensible to vaccine at this short interval.

The inferences to be deduced from a consideration of these experiments are the following:—

I. That three cases re-vaccinated within seven years were not again susceptible to vaccine.

II. That vaccine, after the interval of from eight to seventeen years, does not prevent the reception of vaccine again, except in 22-174 per cent.

III. That the distinctness or imperfection of the vaccine cicatrix does not materially alter these results.

IV. That variola does not prevent the formation of the vaccine vesicle, except in about 23-53 per cent.

V. That the occurrence of small-pox subsequently to vaccination does not destroy the susceptibility of the human system to again receive the vaccine poison, except in about 10 per cent.

VI. That in all the previous cases, whenever the secondary vaccine vesicle assumed its perfect form, its subsequent history was the same as if the system had not previously laboured under vaccine variola or varioloid.

VII. It is probable that the protective influence of vaccination has diminished in consequence of repeated transmission of the vaccine matter through the human body.

VIII. It is desirable that re-vaccination should be extensively followed, as one means of giving additional protection to the masses.

IX. That when possible, the stock of vaccine should be renewed by going back to the original source.

32, Old Market Street, Bristol, March 1853.

CONGENITAL OCCLUSION OF DUODENUM: EXCRETION RESEMBLING MECONIUM PASSED FOR EIGHTEEN DAYS.

By FREDERICK MASON, Esq.

(Read before the Quarterly Meeting of the Bath and Bristol Branch, March 24th, 1853.)

CASE. M. O., born on December 31st, 1852. She was said to have appeared weakly, and to have cried but feebly, and vomited soon after birth. Her mother was attended during labour by a woman. I first saw her on the evening of January 7th, 1853. She appeared to be a small and delicate infant, and was said to have frequently vomited (from the day of birth) a dark brown matter. Besides suckling, she had been fed on gruel, etc. The bowels were not much acted on, but that which passed was said to be quite black. I directed her to be fed only from the breast, and to have a small quantity of hydrargyrum cum cretâ and rhubarb.

January 8th. By daylight she appeared jaundiced, the skin and conjunctiva being very yellow. She winced and showed signs of pain when pressed gently over the right hypochondriac region: the mother had noticed the same when washing her. She had not rejected either medicine or milk; yet there was still frequent vomiting of a dark chocolate-coloured matter, resembling coffee-grounds. The bowels had acted; the evacuations being black, or very dark green, of the colour and appearance of meconium, but somewhat stiffer in consistence. The tongue was clean and red, and constantly thrust out between the lips, rolled round, and drawn in again. She did not appear to have any inclination or sufficient strength for suckling. I prescribed two grains of hydrargyrum cum cretâ three times daily. This treatment, with the addition of a dose of castor oil, was continued for about three days, when the yellowness of the skin disappeared, and it acquired a natural colour; still the coffee-ground vomiting and the dark-coloured motions continued, and she became more and

more emaciated. There was no abatement of these symptoms before her death, which occurred on January 17th.

POST MORTEM EXAMINATION, fifteen hours after death. The body was very much emaciated. On laying open the abdomen, the first things which attracted notice were the stomach and duodenum; they were enormously distended, contrasting strongly with the very empty and shrunken condition of the remaining portion of the intestines. On raising the liver, the rudiments of a gall-bladder were seen lying flat, and like a small membrane, on the liver. On carefully dissecting the bile-ducts, the cystic was found to be impervious and threadlike. The hepatic and common ducts were pervious, and entered into the distended portion of the duodenum. The stomach and duodenum were filled with a dark greyish fluid; and when removed from the body, the duodenum at first appeared to be only a *cul-de-sac*. When the remainder of the intestines was removed, and the duodenal end sought, it was found very transparent and thin, and had inadvertently been separated by the knife from the duodenum. The interior of the stomach and duodenum was now examined, and a complete septum was found stretching across the duodenum, which completely closed it, and prevented the passage of anything into the jejunum. The whole of the intestines below the septum was in a normal condition. The other organs were healthy.

REMARKS. One of the most remarkable symptoms in this case appears to be the fact, that, notwithstanding that all communication between the portion of intestines below the duodenum was cut off from the stomach and duodenum, and also from the liver, by means of the septum in the lower part of the duodenum, yet an excretion, resembling meconium in colour, but differing from it in being thicker and more pasty in consistence, continued to be discharged from the bowels frequently during each day, until the time of the infant's death. On the morning of this day (17th January), there was one evacuation; and this must have completely emptied the bowel, as after death nothing remained in any part below the duodenum.

On referring to the second edition of Müller's *Physiology*, page 165, I find it stated that "it is the excrementitious matter of the bile of the fœtus, which collects together with intestinal mucus in the lower part of the canal, forming the meconium."

In this case it would appear that the bile could have had nothing to do with the formation of this excretion, all communication with the liver being cut off by the occlusion of the duodenum below the entrance of the bile-duct.

5, Cleveland Place East, Bath, March 1853.

CASE OF STOMATITIS MATERNA DURING PREGNANCY.

By WILLIAM HENRY CULLEN, M.D.

THE following case seems to bear on others contained in an article in the *Periscopic Review* at p. 213 of the *ASSOCIATION JOURNAL* for 11th March, entitled "Stomatitis Materna". I send it for publication, as you therein express a wish to have an account of any similar cases which may have occurred in the experience of members.

CASE. In May 1849, I was called to see Mrs. J., who was suffering severely from salivation, in the sixth month of pregnancy with her sixth child. The discharge was so profuse as to compel her to have always a small basin at hand to receive the stream of saliva which would produce vomiting if she attempted to swallow it. No mercury had been taken, and, with the exception of slight heartburn, the general health was good. I prescribed antacids with some relief. In June, the symptoms all returned with increased severity. The tongue and lining membrane of mouth were unnaturally clean, of a deep red colour, and covered with small ulcers. The sides of the tongue were furrowed with deep cracks or fissures, so that talking produced great pain. Only gruel and arrowroot could be taken, (though the appetite was

good,) and that only when nearly cold. I gave mild mercurials as the liver was inactive, applied the solid caustic freely to the tongue and apththæ: and finding no directions in any work I could refer to as to the treatment of so severe a form of stomatitis materna, and that antacids in every variety and combination failed to give the least relief, I prescribed on the 6th July the following:

R.—Pulveris tragacanthæ comp. 3j.
Tincturæ hyoscyami 5j.
Infusi pareiræ 3iv. M.
Fiat mistura cujus capiat partem 4tam bis terve die.

Marked relief followed the use of this, which was persevered in till the middle of August, when she was delivered of a daughter after a very easy labour, and made a rapid recovery. If the pareira was left off for more than a day, and she attempted to take meat, or even a boiled chicken, a relapse was sure to follow. There was no symptom, as in the American cases, of any affection of the mucous follicles of the intestines. The symptoms entirely disappeared after delivery.

Sidmouth, Devon, April 1853.

PERISCOPIC REVIEW.

OPHTHALMOLOGY.

ON COLOUR-BLINDNESS.

In the *Athenæum* for January 20th, Mr. W. H. TYNDALL pointed out the danger arising from the use of colour signals on railways; where red signifies danger; green, caution; white, safety.

White light, it is well known, consists of three primary colours, red, blue, and yellow; any two of these producing the secondary colours; thus, red and blue give violet, the complementary colour of which is yellow: red and yellow give orange, to which blue is complementary: whilst blue and yellow give green, of which red is the complementary: hence it follows that when a secondary is mixed with its proper complementary colour, white light results. Now, with the colour-signals used on railways, it so happens, as will be evident from the foregoing, that if the danger and the caution colours, viz., red and green, are combined, the safety colour, or white light, is produced. On putting this to the test of experiment, Mr. Tyndall found that when a pointsman, stationed at one end of a tunnel some four hundred yards in length, was directed to report the signals made by a man placed at the other extremity of the tunnel, who was furnished with two lamps, a green and a red one, and directed to flash them together, the pointsman, a practised hand, declared that the light was white, indicating safety; nor could he be persuaded that the red and green lamps were used, in spite of subsequent explanation. Thus the very means now adopted for attaining safety, in practice involves the greatest risk; since the danger and caution colours, when seen together, or in rapid succession, at a distance, produce the impression on the retina of the safety signal; and may, probably, already have actually been the cause of the most frightful accidents, when we remember the contradictory evidence given on inquests with respect to the colour of the signals.

Dr. George Wilson, of Edinburgh, author of *The Life of Cavendish*, in a letter to the same journal of the week before last, directs attention to an additional source of danger arising from this use of coloured signals on railways, owing to the frequency of Daltonism, *Chromatopsedopsis*, or colour-blindness, which, since the interest excited by Dalton's publication of a defect in his vision, which led him to confound scarlet with green, has been found to be far more prevalent than might be imagined, and thus increases the probability of danger arising from use of coloured signals. He first of all remarks that colour-blindness is a very common affection; Prévost declaring that it occurs in one male among twenty; whilst Seebeck found five cases among forty youths in Berlin. Dr. Wilson states, that amongst his own pupils (in chemistry) this winter he has detected two marked instances, and that five others have made themselves known to him; one of the two pupils having four relatives also subject to this affection. Professor A. Thomson, of Glasgow, made a similar investigation some years since, and arrived at the conclusion that from the frequency of colour-blindness, the use of coloured signals on railways, or elsewhere, is fraught with peril to the public.

Further investigation amongst the students at Edinburgh shows that 1 in 37 or 38 are defective in the appreciation of colour, this defect appearing to be almost exclusively confined to males, amongst whom are to be found painters (artists), dyers, stationers, surgeons, a shawl-manufacturer, and an enamel-maker, employments we should have presumed to require the nicest appreciation of colour.

It also would seem that this defect is usually so great as to incapacitate those who are subject to it from distinguishing some colours, and especially red from green, and green from red, the railway signal colours; thus four of Dr. Wilson's own cases were unable to distinguish these colours; three instances observed by Professor Kelland were similar to and as marked as Dalton's own case; one of the surgeons, above alluded to, betrayed his defect by his inability to distinguish the scarlet of the berries of the mountain-ash from the green of its leaves: another supplied himself in Paris with a *bonnet-rouge* in lieu of a green cap as he intended, and still worse, brought home a flamingo-coloured dress to a lady who had requested him to procure her a green one. Others are unable to distinguish ripe from unripe strawberries but by the touch; one stationer offered blue sealing wax for red, others made continual blunders about the colours of the bindings of books, the colours of pink and green tinted paper, etc.; all of these proving the frequency of this inability among the community to distinguish between red and green colours.

Dr. Wilson also finds that, in the cases he himself has observed, and also, he thinks, in those of Professor Kelland, there was not merely *chromatopsedopsis*, but actual colour-blindness; so that they did not merely confound green with red, but doubted about every colour; and, on different occasions, gave different names to the same colours; betraying an imperfect appreciation of all colours, confusing one with another. On these grounds, he recommends a speedy investigation of all the railway officials who are entrusted with or observe signals, in order to detect the cases of colour-blindness which probably occur amongst them, with a view to remove this cause of public peril, or, at any rate, an alteration of the signals employed, so as to avoid the danger thus incurred; concluding by requesting statistics on this subject from all who may feel interested in it, for which purpose we subjoin his address,* that such of our members who may be so disposed may communicate the results of inquiries in their own practice to a quarter where these results may be tabulated, and probably lead us to some interesting conclusions upon this singular optical affection. The comparative freedom of females from this affection is very remarkable; Dr. Wilson stating that only six female cases are as yet on record.

ASSOCIATION INTELLIGENCE.

MEDICAL BENEVOLENT FUND.

At the last monthly meeting of the Committee, it was announced by the Treasurer, that one of the annuitants, who was blind, had lately died, leaving his widow and child in great distress. Voted £10.

Letters of acknowledgment of the receipt of monies, voted at the previous meeting, having been read, the Treasurer stated, that since July 1852, the sum of £500 15s. had been received in annual subscriptions, and £296 14s. in donations; that the expenses had been £51 12s. 3d., and that £489 had been spent in grants, leaving the sum of £20 due to the Treasurer.

The following cases were presented:—

- i. The widow of a surgeon of Nottingham, who died in February last, having practised there thirty years, leaving eleven children, eight of whom are unprovided for. Voted £25.
- ii. The wife of a physician lately practising in London. Left in great distress. Voted £5.
- iii. The wife of a medical man, whose husband is imbecile, and who supports herself, husband, and two children, by letting lodgings. Relieved twice previously. Voted £5.
- iv. The widow of a medical man, also relieved previously. She supports herself by going out as a governess, and her two daughters, who are in bad health, endeavour to support themselves by working as milliners. All at present in difficulties. Voted £10.

[We did not receive this report till Monday, the 11th current.—EDITOR.]

EDITOR'S LETTER BOX.

GENUINE LYMPH MORE IMPORTANT THAN A COMPULSORY VACCINATION ACT.

LETTER FROM J. A. HINGESTON, ESQ., TO THE EDITOR.

SIR,—Will you favour me with the insertion of the few following lines in the next number?

I find, by a letter from Mr. Ceely, that I have not represented Dr. Thiele's experiments accurately in my article on *Vaccine Lymph*, in your impression of the 1st of April. Mr. Ceely's words are:—"In the article (*vaccine*), page 270, I do not think the phrase used, in speaking of Dr. Thiele's experiments, quite expressive of the fact. Dr. T. *selected* milch cows; *rejecting* others which I was *compelled*, from circumstances, to *take*, and did *succeed* on such as he *rejected*." So I have stated in a note at the conclusion of my paper in the eighth volume of the *Transactions of the Provincial Medical and Surgical Association*.

I take this opportunity of saying a few words on the subject of vaccination, in relation to Lord Lyttelton's Compulsion Bill in the House of Lords. The question is not whether vaccination shall be compulsory, which may or may not be advisable; but whether the vaccine lymph shall be genuine: in default of which compulsory vaccination, good, bad, or indifferent, as it may be in the abstract, would become practically nugatory. If his Lordship would inquire into the circumstances of the case, he would learn that the chief want among medical men is that of genuine lymph. During the present week, I have received two letters, one from Mr. Wilson, of Runcorn, Cheshire, and the other from Dr. John Grigor, Nairn, N.B., both complaining of the inefficiency of the lymph they use, and begging for a more effective supply of it from Mr. Badcock's stock. These cases are not solitary, and they exclude the idea of any advantage being derived from compulsory vaccination.

I am, etc.,

J. A. HINGESTON.

Brighton, April 9th.

CAUSE OF THE OUTBREAK OF CHOLERA IN THE BAHAMAS.

LETTER FROM H. N. CHIPMAN M.D., TO THE EDITOR.

SIR,—I received, per last packet, the ASSOCIATION MEDICAL JOURNAL of January 17th, containing a copy of my letter to Dr. Cogswell regarding the outbreak of cholera here, etc.

I am happy to say that it has now entirely left our shores, although probably, as in other instances, it may again revisit us. The mode of its introduction, whether by importation or otherwise, is involved in much obscurity. The general belief among the non-professional is, that it was introduced here by the schooner *Reform*, a vessel belonging to this port, and which had conveyed a cargo of pineapples to New York in August last. She lost a man from cholera while in the port of New York, but the disease did not extend to any of the crew, and she reached this island in September, and was undergoing some cleansing in the vicinity of the spot where the disease first manifested itself. I cannot myself think that she had anything whatever to do with its introduction. It is, however, true that the first case which showed itself was that of a Mrs. Hall, an elderly female, who had been to a house near her own, on the Eastern Parade, where the captain of the said schooner *Reform* resided, and who spent some time with him, making inquiries about her son, who commanded a vessel then expected from Philadelphia. Mrs. Hall died suddenly of cholera on the 17th September. I am aware that your own opinion is rather that of a contagionist, judging from a communication which I remember having seen in the *Medical Gazette* some time since. I hardly have myself arrived at any very definite conclusion upon this very important point. I do not wish to be decisive upon so vital a question without further experience, although I am free to confess that much perplexity surrounds the subject, in the same manner as that which exists upon the contagiousness or otherwise of yellow fever. If typhus fever be contagious, as it is now generally acknowledged to be, why not yellow fever?—why not cholera, which appears to me allied to this class of diseases? Scarlet fever, also, we admit into the category, and does not this often fatal affection sometimes present itself to us, as it were, in the collapse stage, the patient suddenly sinking upon the first invasion without the manifestation of its more developed symptoms? The poison which ordinarily, when not so rife, not so virulent, shows itself in lesser degrees, in the shape of intermittent, in stronger is remittent, and, in its somewhat more potent influ-

ence, yellow fever, and in its most powerful, cholera. I dare say you may think this a very crude speculation on my part; nevertheless, I cannot but fancy that such ideas may, with more enlarged experience, be found to be something more than "the baseless fabric of a vision". We all of the profession strenuously opposed the idea of contagion; and, by our example, I trust we carried out the idea that *cholera is not contagious*. Fearful as has been the havoc which the disease has made, I believe the coolness, and disregard to the doctrine of contagion, has saved many lives; and, on this account, such a belief should not be admitted without the most decisive testimony.

I am, etc.,

H. N. CHIPMAN.

Nassau, 7th March, 1853.

AGITATE IN FAVOUR OF THE MEDICAL BILL.

LETTER FROM J. D. JONES, M.D., TO THE EDITOR.

SIR,—The much-desired and long-pending Medical Reform question is at last before the profession. I have weekly looked, but looked in vain, for some editorial suggestion or direction as to the best mode of agitating. For it must be well known to all that have had anything to do with political questions, that nothing short of agitation will wake the medical profession from its usual apathy. Its members always trust to some other hands than their own for doing all that is desirable or necessary; but rouse them, and they will be made to understand the necessity of individual as well as collective action.

I had an opportunity some years ago of witnessing this to a most extraordinary extent: I allude to the period when a "Medical Registration Committee" held its weekly meetings at the Freemasons' Tavern, under the able leadership of Dr. Lankester, as chairman. The immense power wielded by that committee, although up to that time most of its names were unknown to the profession, would be scarcely believed by those unacquainted with its operations.

Remembering this, it occurred to me that a similar demonstration ought to be made at the present time. I would suggest first a general meeting, not only of the Metropolitan Counties Branch of the Association, but of the profession generally; and at this meeting, a committee to be elected to organize a plan of operation.

Without some such agitation, this Bill, like all its predecessors, will die a natural death, or, more correctly speaking, an unnatural death; but, with the assistance of the great body of the profession, such a consummation may be readily avoided. I then say agitate, agitate, agitate! To you, sir, we look for direction in this affair. The present Medical Bill is the Bill of our ASSOCIATION, of which you are at the present moment the eye and the hand. Use these organs vigilantly and vigorously, and doubt not the successful result.

I am, etc.,

J. DALSTON JONES, M.D., F.L.S.

Dalston, April 9th, 1853.

THE MILITIA BALLOT:—MEDICAL MEN NOT EXEMPT.

LETTER TO THE EDITOR.

SIR,—You would confer a favour upon me, and upon many others, by suggesting to our Parliamentary friends the great hardships of the Militia Ballot to medical men. It presses with peculiar severity upon the juniors, who are often unable to meet the expense of providing substitutes. In reading over the various Acts, I find that clergymen are totally exempt. Surely our claim is far stronger than theirs, as their duties can all be performed equally well by deputy, whereas ours cannot. Will you kindly suggest, in your next number, what steps ought to be taken to remedy this grievance?

I am, etc.,

V.

Southwold, April 1853.

[As far as we can discover, our correspondent is quite right as to medical men not being exempt from the Militia Ballot. The Acts are 15 & 16 Victoria, cap. 50, and 42 George III, cap. 90. Most of the men have, we believe, been raised voluntarily under the recent Act; but still that is no reason why the statute should not exempt the medical profession as well as the clergy from serving. As to the steps which ought to be taken to remedy this grievance, we can suggest none better than frequently agitating the question in the *Times* and other newspapers, as well as in the medical journals; bringing the subject before the Branch Societies of our Association; and using every

influence that can be commanded with the government or with private members of parliament. The topic might furnish us with an excuse for preaching over again an old sermon from a new text; but from this we abstain, as we have already, in the present number, exceeded the bounds which convenience assigns for our leading articles. Let us remark, however, that all sorts of injustice will continue to be inflicted upon our profession, from ignorance of its claims and wishes, so long as there are no able and trustworthy members of our own body sitting in the House of Commons. It matters not whether our colleagues enter parliament as the representatives of universities, counties, or burghs; but they must, if they are to be of the slightest use, be *bona fide* practitioners—sterling men, business men, and men who are thoroughly imbued with professional sympathies and independent patriotism.—EDITOR.]

THE PLACE AND DATE OF ORFILA'S BIRTH, AND THE DISEASE OF WHICH HE DIED.

LETTER TO THE EDITOR.

SIR,—I do not find the place of Orfila's birth stated in any of the recent biographies which have appeared of the illustrious deceased, either in the French or English journals. I observe, however, that you mention, in your leader of 18th March, that "he was born in Spain, at the frontier town of Mahon." Will you kindly mention in next number, upon what authority you made that statement, and inform me, at the same time, of the date of Orfila's birth, and the immediate cause of his death?

I am, etc., G. Y.

Edinburgh, April 11th, 1858.

[In travelling in Spain in 1840, the writer of the leader referred to, when visiting the University of Valencia, was informed by one of the professors that Orfila was born at Mahon, and, from a note made at that time, the statement was transferred to the ASSOCIATION JOURNAL. The Spanish medical journals just received confirm the accuracy of the statement. The *Heraldo Medico* of 24th March has the following paragraph in its biography, which is quite in point, and describes Orfila's start in life:—

"Mateo José Orfila nació el 27 de abril de 1783, en Mahon, de una familia de comerciantes, que en 1802 le dedicó a la marina y le embarcó en clase de segundo piloto. En 1805, el joven marino, que se sentía inclinado al estudio de la ciencia médica, abandonó la carrera naval y fué a Valencia, donde empezó sus estudios de medicina. Un año después, ganó el primer premio de física y de química."

Mahon is not on the French frontier, as we stated, but is in the island of Minorca. The immediate cause of Orfila's death was pleuro-pneumonia.—EDITOR.]

MEDICAL FEES AT INSURANCE OFFICES.

LETTER FROM PATRICK FRASER, M.D., TO THE EDITOR.

SIR,—Having observed with great interest several letters which have been published recently in the Journal, respecting the non-payment of medical men, by Life Assurance Societies: I think it right to draw attention to our advertisement, which has appeared in the *Times* newspaper and elsewhere, in which it is stated that the Directors will "award a consultation fee of Two Guineas for every medical report rendered to the Company, when the proposed assurance is not less than 300*l.*; and of One Guinea when under that amount"; and that "the Directors will always, when practicable, appoint the medical attendant of the assured their adviser, as possessing, without doubt, the best means for forming an accurate opinion on the case". The Directors have also determined that all medical reports shall be transmitted direct to the medical officer of the Company at the head office in London.

I am, etc.,

PATRICK FRASER, M.D.,

One of the Medical Officers of the Company, and a Member of the Provincial Medical and Surgical Association.

Guildford Street, Russell Square, April 13th, 1858.

THE OBSOLETE SYSTEM OF THE ENGLISH UNIVERSITIES.

SIR,—In your leading article on the Success of Medical Improvements, at p. 287, you say: "The theology, the science, and the statesmanship of the Universities are sterile, sapless, monkish,

and mouldy". I do not object to this denunciation of the university system; but I think it would be well to accompany it with some allusion to the exertions which are now being made, not only by Parliament, but also by a reforming body within the Universities themselves, to remodel and modernize their system of education. It ought not to be forgotten that Dr. Ogle, the President of our ASSOCIATION, and Regius Professor of Medicine in the University of Oxford, announced himself, at the last Anniversary Meeting, as a reformer; and, to use his own words, said: "The truth is, that the system transmitted to us from a distant date, and well suited to the state of society a century or two since, is become, through those changes which time, in flourishing states, ever rapidly brings about, in some particulars obsolete." (*Provincial Med. and Surg. Journal*, Aug. 4, 1852, p. 387.)

The insertion of this will oblige

Yours, etc.,

OXON.

London, April 12th, 1858.

NEWS AND TOPICS OF THE DAY.

ROYAL COLLEGE OF PHYSICIANS:—DRAFT OF CHARTER.*

VICTORIA, by the grace of God of the United Kingdom of Great Britain and Ireland Queen, Defender of the Faith, to all to whom these presents shall come greeting: Whereas the Commonalty or Fellowship of the Royal College of Physicians in London have, by their petition, humbly represented unto us, that the said college was incorporated by letters patent, bearing date the twenty-third day of September, in the tenth year of the reign of King Henry the Eighth, which letters patent were confirmed by an Act passed in the Session of Parliament holden in the fourteenth and fifteenth years of the reign of King Henry the Eighth, intituled "The Privileges and Authority of Physicians in London", and that by such Act of Parliament certain other powers and privileges were granted to the said commonalty; and whereas the said college has also represented unto us, that since the making of the said letters patent divers other charters have been granted to the said college: and whereas the said college has also represented unto us, that by an Act of Parliament made and passed in the present year of our reign, intituled "An Act making Provision for the Granting a New Charter to the College of Physicians", after reciting as or to the effect hereinbefore stated, and that it was expedient that certain changes should be made in the constitution of the said college, and particularly that new regulations should be made for the election of the officers of the said college, it was enacted, that it should be lawful for the said corporation to surrender all the charters which had theretofore been granted to them, other than and except the said charter of King Henry the Eighth; and also so much and such part of the last-mentioned charter as should be in anywise inconsistent with or repugnant to any new charter to be granted to them by us; and that it should be lawful for us to grant and for the said corporation to accept from us a new charter, which charter might make such alterations as should be deemed by us expedient in the constitution of the said corporation, and might, if we should so think proper, change the name of the same corporation; and further, that when and so soon as the said corporation, under their then present common seal, should have accepted any new charter so to be granted as aforesaid, the acceptance thereof should operate as a surrender of all the other charters of the said corporation, except the said charter of King Henry the Eighth, and should also operate as a surrender of the said charter of King Henry the Eighth, and as a repeal of the first-mentioned Act of Parliament, so far as the same should be inconsistent with or repugnant to such new charter; and further, that from and after such acceptance of such new charter, the said charter of Henry the Eighth should stand, and be ratified and confirmed, except so far as the same should be so surrendered as aforesaid: Provided always, that nothing therein contained should extend to authorize us to create any new restriction in the practice of physic, or to grant to the said corporation any new powers or privileges contrary to the common law of the land; and that no such new charter, whether the name

* Clauses 5 and 6 are drawn under the supposition that the Legislature will, in future, and without interfering with existing legal rights, or the privileges of the Universities of Oxford and Cambridge, require it to be established upon all physicians practising in England and Wales, as being created by the College of Physicians of England.

of the corporation should be changed or not, should in anywise prejudice, affect, or annul any of the existing statutes or bye-laws of the said corporation further than should be necessary for giving full and complete effect to the alterations which should be intended to be effected by such new charter in the constitution of the said corporation: now know ye, that we, taking the premises into our royal consideration, of our especial grace, certain knowledge, and mere motion, have granted, declared, ordained, and appointed, and by these presents, for us, our heirs and successors, do grant, declare, ordain and appoint, in manner following, to wit:

i. That the said corporation shall henceforth be styled, "The Royal College of Physicians of England".

ii. That the said corporation shall consist of fellows and members, including a president and council, four vice-presidents, four censors, a treasurer, and a registrar.

iii. That all the present licentiates of the said corporation shall be members of the said corporation.

iv. That each of the present extra licentiates of the said corporation may be admitted a member of the said corporation on the production to the said censors of the said corporation of testimonials of character which shall be satisfactory to the said censors, and on his assuring the said censors that he is not engaged in the practice of pharmacy, and on his paying to the said corporation a fee of fifteen pounds fifteen shillings exclusive of the stamp duty.

v. That every person practising as a physician in England or Wales, and who shall have taken the degree of doctor in medicine at any university in the United Kingdom of Great Britain and Ireland, after regular examination at least three calendar months previously to the date of these our letters patent, and also every person who shall have received a license to practise physic from either of the Universities of Oxford or Cambridge, and also every person practising as a physician in England or Wales who shall have taken the degree of doctor in medicine at any foreign university at least three months previously to the date of these our letters patent, after regular examination and after having resided during a period of not less than two years in an university, and also every person practising as a physician in England or Wales who shall have been for a period of not less than three months previously to the date of these our letters patent a fellow of the Royal College of Physicians of Edinburgh, or a fellow or licentiate of the Royal College of Physicians of Dublin, and who shall have been admitted as a fellow of such Royal College of Edinburgh, or Dublin, or licentiate of the Royal College of Physicians of Dublin, as the case may be, after regular examination, provided such person shall have attained the age of twenty-six years, and shall not be engaged in the practice of pharmacy, shall at any time within twelve calendar months from the acceptance of these our letters patent by the said corporation in the manner mentioned in the Act of Parliament hereinbefore stated to have been passed in the present year of our reign, be admitted a member of the said corporation, without any examination, on the production to the censors of the said corporation of his diploma and of such testimonials of character and professional qualifications as shall be satisfactory to such censors, and on his proving himself to be of the said age, and on his assuring such censors that he is not engaged in pharmacy, and on his paying to the said corporation a fee of fifteen pounds fifteen shillings exclusive of the stamp duty.

vi. That any person who after regular examination shall have taken a degree in medicine at any university in the United Kingdom of Great Britain and Ireland, or at any foreign university to be from time to time recognised by the said corporation, and who shall have attained the age of twenty-six years, and shall not be engaged in the practice of pharmacy, and shall have gone through such course of studies, and who shall have passed such examination before the censors of the said corporation touching his knowledge of medical and general science and literature, and complied with such other regulations as are or shall be required by the bye-laws of the said corporation, shall be entitled to become a member of the said corporation without being subject to any other election.

vii. That the present fellows of the said corporation shall continue to be fellows of the said corporation.

viii. That every member who shall be admitted a member of the said corporation as hereinbefore mentioned, who shall be desirous of becoming a fellow of the said corporation, shall be capable of being elected a fellow thereof, provided he shall, in addition to the examination hereinbefore mentioned, at any time after that examination, have passed such further examination before the censors of the said college, touching his knowledge of medical and general science and literature, and complied with

such other regulations, as are or shall be required by the bye-laws of the said corporation: provided nevertheless, that such member shall not be capable of being actually elected a fellow as aforesaid until he shall have been a member of the said corporation for a period of not less than four years.

ix. That during the period of twelve months, to be computed from the date of these our letters patent, the council of the said college shall have the power to nominate such members thereof as in the opinion of the council shall have distinguished themselves in the pursuit of science and literature, provided the members so to be nominated shall have attained the age of thirty years, without any limitation as to the period during which such members shall have previously been members of the said corporation, to be proposed to the fellows for election as fellows at meetings of the fellows to be holden, with due notice, for this purpose at any time before the expiration of the said twelve months.

x. That after the expiration of the period of twelve months, to be computed as aforesaid, the council of the said college shall have the power to nominate yearly such members thereof as in the opinion of the council shall have distinguished themselves in the pursuit of science and literature to be proposed to the fellows for election as fellows, provided the members so to be nominated shall have been members of the said corporation for a period of not less than four years.

xi. That the fellows of the said corporation shall be elected by ballot at a meeting of the fellows, and that after the expiration of the period of twelve months, to be computed as aforesaid, such meeting shall be held yearly on the twenty-fifth day of June, unless the same shall fall on a Sunday, and then on the twenty-sixth day of June; and that the first of such meetings shall be held on the twenty-fifth day of June (or twenty-sixth day of June), one thousand eight hundred and

xii. That if it shall at any time hereafter appear that any present or future fellow or member of the said corporation shall have obtained admission to the said corporation by any fraud, false statement or imposition, or that he shall have violated any bye-law, rule or regulation of the said corporation, then and in every such case, and after such previous notice to and such hearing of such fellow or member as under the circumstances the president and censors of the said corporation shall think proper, it shall be lawful for a majority of the fellows present at a meeting of the fellows to declare such fellow or member to be expelled from the said corporation, and thereupon every such fellow or member shall cease to be a member or a member and fellow of the said corporation, as the case may be, accordingly, and all the privileges granted to such member or member and fellow, as the case may be, shall cease and be extinguished.

xiii. That the present president of the corporation shall continue to be president of the said corporation until a new president shall be actually appointed in his place, and that upon the day next after Palm Sunday in the year one thousand eight hundred and , and on the same day in every subsequent year, a new president of the said corporation shall be elected at a meeting of the fellows of the said corporation; but the retiring president shall always be capable of being re-elected, and every president shall remain in office until the actual election of the new president.

xiv. That at the meeting of the fellows held for the election of the new president, the council of the said corporation shall, out of the first fifty fellows in the list of fellows of the said corporation, nominate some one of such fifty fellows to be proposed to the fellows of the said corporation to be by them elected president; but if the fellow so nominated shall not be elected president by a majority of the fellows present at such meeting, another fellow shall in like manner be nominated by the council out of the first fifty fellows in the list of fellows to be proposed as aforesaid, and so on until a president shall have been elected: the election of president shall be taken by ballot, and in case of any difference in the council concerning their selection of a president, the president nominated by the majority shall be proposed to the fellows, and in case of an equality of votes in the council, the senior fellow so nominated shall be so proposed.

xv. That in case of the death or resignation of the president for the time being, a new president shall, with all convenient speed, be elected in his place, such election to be made in all respects in the same manner as is provided in the last preceding regulation.

xvi. That at any time before or at the meeting of the fellows of the said corporation, after the meeting of the fellows at which the president of the said corporation shall have been elected, the president so elected shall appoint four fellows out of the first fifty on the list of fellows, which four fellows shall be called

vice-presidents, any one of whom may act as president in the temporary absence of the president, upon such president expressing his desire to such effect to any such vice-president, in writing, or to the registrar; and in case of the death of the president, the first vice-president for the time being in the list of vice-presidents shall act as a president until a president shall have been appointed, and the present president of the said corporation shall, at the meeting of the fellows of the said corporation next after the granting of these our letters patent, appoint four vice-presidents for the purposes aforesaid.

xvii. That the vice-presidents shall cease to be vice-presidents when a new president shall have been appointed in the place of the president by whom they were nominated.

xviii. That there shall be sixteen fellows on the council of the said corporation.

xix. That the present council of the said corporation shall continue to be the council of the said corporation until a new council shall have been actually elected in their place, and that on the twenty-second day of December next four fellows shall be elected to make up the number of the council to sixteen, and that on the twenty-second day of December, one thousand eight hundred and , and on the same day in every year (except when the same shall fall on a Sunday, and then on the twenty-third day of December) four of the council shall go out of office, and four fellows shall be elected of the council: but the fellows going out of office shall not be re-eligible until they have been one year out of office, and the fellows to be elected as aforesaid shall remain in office until others shall have been actually elected in their place; and that on the same day other fellows shall be elected to the council to fill up vacancies occasioned by death or resignation since the last election.

xx. That the council shall be elected by the fellows out of their own body by ballot, either by list or otherwise, as the said corporation shall from time to time determine by the bye-laws.

xxi. That in addition to the sixteen fellows so elected, the president, censors, and treasurer of the said corporation shall ex officio be of the council of the said corporation.

xxii. That the present censors of the corporation shall continue to be the censors thereof until new censors shall have been actually elected in their place, and that on the day after Palm Sunday, in the year one thousand eight hundred and , and on the same day in every subsequent year, four new censors shall be elected, and censors going out of office shall be re-eligible, and the censors to be elected as aforesaid shall remain in office until other censors shall actually have been elected in their place.

xxiii. That on the day for electing censors, the council shall nominate four of the fellows of the said corporation to be proposed to the fellows to be by them elected censors, but if any fellow or fellows so nominated shall not be elected a censor or censors by a majority of the fellows present at the meeting, another fellow or fellows shall be nominated at such meeting by the council to be proposed to the fellows, and so on until four censors shall have been elected. The election of censors shall be taken by ballot. In case of a difference in the council concerning the nomination of censors, the censors nominated by the majority shall be proposed to the fellows, and in case of an equality of votes in the council, the president or chairman of the council shall have a casting vote.

xxiv. That in case of the death or resignation of either of the censors for the time being, a new censor shall with all convenient speed be elected in his place, such election to be made in the same manner as is provided by the last regulation.

xxv. That the present treasurer of the corporation shall continue to be treasurer of the said corporation until a new treasurer shall be actually elected in his place, and that on the day after Palm Sunday, in the year one thousand eight hundred and , and on the same day in every subsequent year, the president shall nominate one of the fellows to be elected by the fellows as treasurer in the same manner in all respects as is before appointed for the election of censors by the fellows, and the treasurer shall be re-eligible, and every treasurer shall remain in office until a new treasurer shall be actually elected in his place.

xxvi. That in case of the death or resignation of the treasurer for the time being, a new treasurer shall with all convenient speed be elected in his place, such election to be made in all respects in the same manner as is provided by the last preceding regulation.

xxvii. That the present registrar of the said corporation shall continue to be the registrar of the said corporation until a new registrar shall be actually elected in his place, and that on the day after Palm Sunday, in the year one thousand eight hundred

and , and on the same day in every subsequent year, the president shall nominate one of the fellows to be elected by the fellows as registrar, in the same manner in all respects as is before appointed for the election of censors by the fellows, and the registrar shall be re-eligible, and every registrar shall remain in office until a new registrar shall be actually elected in his place.

xxviii. That in case of the death or resignation of the registrar for the time being, a new registrar shall with all convenient speed be elected in his place, such election to be made in all respects in the same manner as is provided by the last preceding regulation.

xxix. That the president, council, censors, treasurer and registrar shall be considered as remaining in office during the whole of the day on which their successors shall be elected.

xxx. That the said corporation may from time to time by a bye-law change the day hereby appointed for any election to take place, and if from any cause whatsoever any election shall not take place on the day hereby or by any bye-law appointed for that purpose, the same shall take place on some other day appointed for that purpose by the said corporation.

xxxi. That proxies shall not be allowed at any election.

And we do hereby, for us and our heirs and successors, further grant that the duties, powers and privileges of, and incident to, the said respective offices shall, except so far as the same are varied by these presents, and subject to any variations therein which may be made by the said corporation, continue to be the same as the duties, powers and privileges of the same offices respectively now are:

And we do hereby, for us and our heirs and successors, further grant that it shall be lawful for the said corporation to admit as a member of the said corporation any person who shall have exceeded the age of forty years, on the production to the censors of the said corporation of such testimonials of professional education as shall be satisfactory to such censors, and on passing such examination before the censors as shall be required by, and shall be satisfactory to the said censors, and such person shall, after such his admission as a member of the said corporation, be entitled to have and use the degree or designation of Doctor of Medicine:

And we do hereby, for us and our heirs and successors, further give and grant unto the said corporation full and lawful power and authority to hold, possess and enjoy, for the use and benefit of the said corporation, all manors, messuages, lands, tenements, rents, services, possessions or hereditaments whatsoever (whether the same are or shall be holden of us, our heirs and successors, or of any other person or persons whomsoever), already given, granted, sold, aliened, assigned, disposed of, devised or bequeathed unto or to the use of or in trust for the said corporation, and to have, hold, take, purchase, receive, possess and enjoy for the use of the said corporation any other manors, messuages, lands, tenements, rents, services, possessions or hereditaments whatsoever (whether the same are or shall be held of us, our heirs and successors, or of any other person or persons whomsoever), so as that such other manors, messuages, lands, tenements, rents, services, possessions or hereditaments hereinafter to be had, holden, taken, purchased, received, possessed or enjoyed by the said corporation, shall not at any one time exceed in value the clear yearly value of ten thousand pounds above all reprises, according to the value thereof when respectively acquired by the corporation:

And we do hereby, for us and our heirs and successors, further give and grant unto every subject or subjects whatsoever of us, our heirs and successors, whether incorporated or not incorporated, special licence, power, faculty and authority to give, grant, sell, alien, assign, dispose of, devise or bequeath unto the said corporation, for the use and benefit of the said corporation, any manors, messuages, lands, tenements, rents, services, possessions or hereditaments whatsoever (whether the same are or shall be holden of us, our heirs and successors, or of any other person or persons whatsoever), so as that the same do not, at any one time exceed in the whole the clear yearly value of ten thousand pounds above all reprises, according to the value thereof respectively when acquired by the said corporation:

And we do hereby, for us and our heirs and successors, further grant that all the said provisions in the said Act of Parliament of our present reign shall be, and the same are hereby expressly confirmed in such and the same manner to all intents, constructions and purposes as the same might have been by being herein repeated; but this present provision shall not be deemed in any way to weaken, control or affect the provisions of the same Act of Parliament or any of them:

And we do hereby, for us, our heirs and successors, further

grant unto the said corporation and their successors, that these our letters patent, or the enrolment or exemplification thereof, shall be in and by all things good, firm, valid, sufficient and effectual in the law, according to the true intent and meaning thereof, notwithstanding the not fully or duly reciting the said letters patent, or the date thereof, or any other omission, imperfection, defect, matter, cause or thing whatsoever to the contrary thereof in anywise notwithstanding: In witness whereof we have caused these our letters to be made patent: Witness ourself, at our Palace at Westminster, this
day of _____ in the _____ year of our reign.

ROYAL COLLEGE OF PHYSICIANS:—DEPUTATION TO LORD PALMERSTON.

On Wednesday, April 6th, a Deputation of the Fellows of the Royal College of Physicians waited on Lord Palmerston, at his official residence in Downing Street, for the purpose of urging upon his lordship the propriety of taking such immediate steps as may be deemed necessary to obtain a new charter for the College.

The Deputation consisted of the following Fellows:—Dr. Paris, President of the College; Dr. Monro, Treasurer; and Dr. F. Hawkins, Registrar,—the Elects; Drs. Todd, Crawford, Webster, and Owen Rees,—the Censors; Drs. Meryon, Wilson, Spurgin, Alderson, Waterfield, Burrows, Copland, Tweedie, F. Farre, Aldis, Nairne, Daniell, Gooden, A. J. Sutherland, Barlow, Sayer, Rigby, Risdon Bennett, Kingston, Weber, Gull, King Chambers, Henry Monro, Philp, Basham, George Johnson, Peacock, T. Thompson, Barclay, and Sieveking.

Dr. PARIS (President) opened the business of the Deputation by stating that the ancient charter under which the College had been incorporated, and which still regulated its proceedings, was now productive of serious inconvenience to the institution itself, to the medical profession generally, and to the public. The present charter was not ill adapted to the age in which it had been granted; but since railway travelling had made the nation like one great city, the divided jurisdiction which the College possessed with regard to licensing in the town and in the country occasioned great inconvenience to the members of the medical profession, gave rise to unpleasant feelings amongst them, and, in a word, led to results as little advantageous to the community at large as to the medical profession. He hoped that the noble lord would perceive the propriety of doing everything in his power to facilitate the introduction of a more satisfactory state of things. With his lordship's permission, Dr. Hawkins, the Registrar of the College, would submit a statement which would comprise in a few sentences all that need be said upon the subject.

Dr. HAWKINS then read the following statement:—

The President and Fellows of the Royal College of Physicians desire respectfully to represent to Lord Palmerston that they are charged by the legislature with public duties which, under the encumbrance of the present charter, it is impossible that they should perform satisfactorily to the profession, beneficially to the public, or creditably to themselves.

They are sure, therefore, that in earnestly requesting Lord Palmerston to obtain for them an amended charter, they shall not appear to his lordship to be importunate or unreasonable.

At present, the College, or more correctly, its Board of Elects, is compelled to grant to any one who applies, and who can pass a sufficient examination, letters testimonial entitling him to practise as a physician in the country, but not in London, or within seven miles round.

Such letters testimonial, or extra license, as they are termed, have the advantage of being exempted from very heavy stamp duty, which is imposed upon licenses for practising in London.

But it is obvious that restrictions upon practice, constituting a person a physician in one place and not in another, are wholly unsuited to the present state of society, and to the close connexion which now exists between the metropolis and the country.

It is certain also that they create class distinctions and dissensions, and that ultimately they lead to contempt of the law; an instance of which is, that some of those who are licensed for the country transfer themselves to London, and practise there, discreditably, because illegally.

Moreover, a large proportion of physicians who are practising in the country, many of them being physicians to county hospitals and large infirmaries, and possessing diplomas from Scotland, Ireland, the University of London, or the continent, are nevertheless deficient in the legal qualifications which the

law requires in this country; for the law of England recognizes no physicians except the licentiates and extra-licentiates of the College of Physicians, and graduates of Oxford and Cambridge licensed to practise; and the last have no legal qualification to practise in London.

It is much to be regretted that persons of education and character should be placed in such a position as to be infringing by their daily practice the common law of the land; and a vast number of the physicians so situated in the country have expressed themselves as most desirous of becoming members of the College, on the terms offered in the proposed new charter.

If, by means of this charter, the College of Physicians of London were made a College for all England, and the College itself improved in some respects as to its internal constitution, there is every reason to believe that much irregular practice, as regards the order of physicians, would be put an end to, and not recur again; and that the public would be enabled, which at present they are not, to distinguish between qualified and unqualified persons; that is, between those whose competence to practise has been properly tested, and others whose pretensions have never been inquired into, or avouched by trustworthy authority, and of whose qualifications there can be no assurance.

Therefore, on public grounds, and not for mere selfish or corporate purposes, the President and Fellows implore the aid of Her Majesty's Government to obtain for them a charter better suited than that with which they are now encumbered to the present state of society, and to the pressing requirements of the medical profession and the public.

FRANCIS HAWKINS, M.D., Registrar.

Royal College of Physicians, April 6th, 1853.

When the perusal of Dr. Hawkins's statement was concluded, Lord PALMERSTON said that he would give to the subject his earliest attention, and lose no time in taking such steps with regard to it as might be deemed necessary.

Dr. BURROWS thought it proper to direct the attention of the noble lord to this fact, that, although the Deputation appeared before him as the representatives of a body of physicians who resided in London, and were anxious to procure for themselves a new charter of incorporation, the object they had in view was one to the principle of which it was not to be anticipated that the slightest opposition would be offered by any other section of the medical profession. Not only were the Fellows of the Royal College of Physicians completely agreed among themselves on the subject of a new charter, but they had reason to believe that the profession out of doors viewed the question with unanimous interest, and were anxious that the College should obtain the object of their ambition. It was not simply out of regard for their own interests that the college desired to be remodelled; they were also influenced by considerations having reference to the welfare of the public and of the profession generally. They had to endure a pressure from without, and were not unfrequently reproached with insincerity for not having acted with sufficient energy and decision in the matter. He believed he was fully warranted in assuring the noble lord that, if the government could be prevailed upon to take the matter into their immediate consideration, they need have but little apprehension of encountering any opposition from the medical profession.

Dr. TODD reminded the noble lord that a short time since he had been waited upon by a Deputation from the Provincial Medical and Surgical Association, who represented very accurately the feelings of the profession in the country with reference to this matter. They stated what he believed to be strictly correct, that the bill which that Association so strenuously advocated was in entire harmony with the charter of the College.

Dr. HAWKINS respectfully submitted that, as the object which the College had in view was one in respect of which no opposition was to be anticipated, it might be as well if the government would direct their attention to it before they took in hand any other matter relating to medical affairs which might give rise to diversity of opinion.

Dr. TODD remarked, that the object which the College had in view was simply to procure the enactment of a law authorising them to surrender their present charter, and to obtain a new one. In that object no other considerations were involved.

Lord PALMERSTON accepted a copy of the statement read by Dr. Hawkins, and repeated his assurance that the subject to which it referred should receive the earliest and most serious consideration of the government.

The Deputation then withdrew.

LORD LYTTTELTON'S VACCINATION BILL.

[House of Lords, April 12th.]

LORD LYTTTELTON moved that the House go into committee on the Vaccination Extension Bill. It was needless to dwell upon the importance of the subject, and he would content himself with quoting some facts from the [unpublished] report of the Epidemiological Society, a new society, of which Sir B. Brodie, Dr. Babington, Dr. Southwood Smith, Dr. Bright, and other eminent medical men, were members. His lordship then read an elaborate statistical statement, from which it was made to appear that, in countries where vaccination was compulsory, small-pox prevailed much less than in England: it likewise showed that vaccination was most general in this country where the greatest facilities were afforded, and where the local authorities best remunerated the vaccinators. He thought that, sooner than pay the fine, the great majority of parents would have their children vaccinated. Another objection urged to the bill was, that it was an undue interference with the liberty of the subject. This objection was founded upon an entire misapprehension of the nature of the evil. He should consider that allowing children to be unvaccinated was distinctly a criminal act, and deserved treatment as such. Moreover, the principle of the bill had been admitted. Inoculation, as their lordships knew, was illegal; and the exposure of children so as to spread infection was also punishable by the legislature. As to the pay of medical officers by the unions for these duties, he feared this was a matter with which he could not meddle. He had contemplated fixing a *minimum* rate of payment in the bill, but he was told that no such provision could be introduced. With regard to the general subject of the remuneration given to the medical officers of unions, he could not wonder that the Poor-law Board and the government felt very great difficulty in interfering on this subject, when they saw medical men of the highest character entering into these contracts year after year, and duly carrying them out. The alterations he proposed did not affect the principle of the bill, and he hoped there would be no objection to them on the part of their lordships.

The Earl of SHAFTESBURY supported the bill by arguments and statistics. As to the amendments of which notice had been given, he must say he agreed in thinking that children should be vaccinated from the arm of a healthy child, for no doubt there was a prejudice against the virus from animals. If the bill were properly carried out, and remuneration given to those engaged under it, he believed they would soon exterminate the disease; and he had not the slightest doubt that generations to come would thank their lordships for the attention they had bestowed on that important subject, and on the blessings that had resulted from it. (Hear, hear.)

The Earl of ELLENBOROUGH observed, that the act now in force had been introduced by him some years ago, but he must admit that it had not produced all the good he had expected from it, and that the noble lord had made out a case for very material alterations. He did not object to the principle of compulsion, but he confessed that it appeared to him rather hard to compel people who had strong feelings against vaccination to bring their children to be vaccinated, unless all their prejudices as to the manner in which the operation was performed were consulted, and every possible facility afforded to them. He therefore would propose a clause to the effect that, in every case, vaccination should be performed from the arm of a healthy child, and that provision should be made for giving people facilities for the operation; and he would suggest to their lordships to adopt some regulations which he had found very useful in his own neighbourhood. He was not indisposed to adopt a plan which appeared to be carried out in other countries, and affix a penalty for sending unvaccinated children to school. Nay, more, he was willing to extend that principle to every person applying for poor-law relief; and he saw no reason why penalties should not be imposed on unvaccinated persons in factories, as it was in schools, manufactories, and large assemblages of persons, that the disease was most apt to spread. He begged to suggest that each union should be divided into proper vaccination districts, as it would prove very inconvenient if they were too large. Finally, in order to give their lordships time to consider the subject, he proposed that all the amendments in the bill should be printed, and that the bill should be re-committed at some future period.

LORD LYTTTELTON assented to the latter proposition.

The House then went into committee, and, several amendments having been agreed to, the House resumed, and the bill was ordered to be read a third time.

MEDICAL BENEVOLENT COLLEGE. At the last meeting of the Council, Lord Dynevor and Thomas Copland, Esq., F.R.S., were unanimously elected Vice-Presidents of the College. Thanks were voted to the Bishop of London for his Sermon in aid of the funds, and to the Rev. Thomas Garnier, of Trinity Church, St. Marylebone, for granting his pulpit on that occasion. The latter gentleman was also elected an Honorary Governor of the Institution.

ST. CLEMENT'S CHURCHYARD. On Monday next, the 18th instant, this churchyard is expected to be closed by the order in Council, under the Nuisance Removal Act. Strange to state, a number of burials, more than ordinary, have lately occurred in this churchyard, (in the very heart of London,) and the parishioners are anxiously looking for the final closing.

ROYAL COLLEGE OF SURGEONS.—PASS LIST. The following gentlemen, having undergone the necessary examinations for the diploma, have been admitted members of the College at meetings of the Court of Examiners.

On the 8th instant:—W. E. Smith, Bristol; J. H. Drew, Southampton; John Jones, Swansea; Alfred Brown, E.I.C.S., Steeple Bumpstead, Essex; Maurice Griffith Evans, Blaenafon, Caermarthenshire; Robert Thomas Simons, Sydney, Australia; John Hawkes, Wells, Somerset; Robert Walker Jenkins, Mansell Street, Goodman's-fields; Horace Kersey Debenham, Queen's-road, Dalston; Robert Dempster, Sussex; William George Nicholas Manley, Barking, Essex; and Thomas Lawes Rogers, Alvediston, Wilts. On the 11th inst.:—Thomas Watson Hudson, Whitehaven, Cumberland; George Ross, London; James Earl Moreton, Marton Hall, Cheshire; Frederick Augustus Strutter, Wickhambrook, Suffolk; Clarence Chapman, Devonshire Street, Portland Place; James Joseph Cregeon, Deptford; Cecil Calvert Cogan, Winsley, Bradford, Wilts; William Forbes Goss, Paternoster Row; William Henry Dodge, St. Austell, Cornwall; Edward Pratt, Appledore, North Devon; and Cyril John Vincent, Oxford.

EPIDEMIOLOGICAL SOCIETY. The annual meeting of this Society was held on Monday. The following gentlemen were elected office-bearers for the year 1853-54.—**PRESIDENT:** Benjamin Guy Babington, M.D., F.R.S.—**VICE-PRESIDENTS:** Thomas Addison, M.D.; Richard Bright, M.D., F.R.S.; Sir B. C. Brodie, Bart., F.R.S.; Sir Wm. Burnett, Knt., K.C.B., K.C.H., F.R.S.; Sir C. M. Clarke, Bart, M.D., F.R.S.; Rev. Thomas Dale, M.A., Canon Residentiary of St. Paul's; R. D. Grainger, Esq., F.R.S.; Sir Charles Hastings, M.D., Worcester; Sir John Liddell, C.B., M.D., F.R.S.; Sir James McGrigor, Bart., K.C.B., K.C.T.S.; John Nussey, Esq.; John Probert, Esq.; G. L. Roupell, M.D., F.R.S.; Thomas Southwood Smith, M.D.; Colonel Sykes, V.P.R.S.; Thomas Watson, M.D.—**TREASURER:** Thomas Addison, M.D., vice-president.—**HONORARY SECRETARIES:** J. O. McWilliam, M.D., F.R.S., R.N., and J. H. Tucker, Esq.—**MEMBERS OF COUNCIL:** C. A. Aikin, Esq.; A. Beattie, M.D.; James Bird, M.D.; Samuel Brown, Esq.; A. Bryson, M.D., R.N.; J. Hall Davis, M.D.; Charles Hawkins, Esq.; E. Headland, Esq.; T. Hunt, Esq.; W. Jenner, M.D.; Waller Lewis, M.B., F.G.S.; C. F. J. Lord, Esq.; J. F. Marson, Esq.; Gavin Milroy, M.D.; A. Nisbett, M.D., R.N.; Hon. Joceline Percy, M.P.; G. Pilcher, Esq.; E. Seaton, M.D.; F. Sibson, M.D., F.R.S.; E. Sieveking, M.D.; Professor Simonds, R.V.C.; J. Snow, M.D.; C. R. Walsh, Esq.; Erasmus Wilson, Esq., F.R.S.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

- CHAMBERS, Richard, M.D., at 38, Wimpole Street, on April 6th. The deceased was found dead in his bed.
- DICKINSON, William Lindow, Esq., surgeon, at Workington, Cumberland, on March 19th, aged 65. We hope to have room on an early occasion to give some account of the career of this excellent man.
- DYER, Thomas, Esq., Surgeon, at Ringwood, Hants, suddenly, from disease of the heart, on April 2nd, aged 62.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

- LUDLOW, Harvey, Esq., elected Surgeon to the Metropolitan Free Hospital.
- REES, George Owen, M.D., elected Examiner in *Materia Medica* to the University of London, in the room of the late Dr. Pereira.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XVI.

LONDON: FRIDAY EVENING, APRIL 22, 1853.

NEW SERIES.

PERISCOPIC REVIEW. The simultaneous claims upon our columns of long ORIGINAL COMMUNICATIONS and of urgent PUBLIC QUESTIONS, have obliged us for several weeks past to delay much valuable matter destined for this department. We can assure several correspondents who have addressed us on this subject, that we have no intention of permanently curtailing the *Periscopic Review*. We do not expect to be often called on to occupy so much space with editorial articles and official documents, as in last number.

MEDICAL REFORM. Correspondents are informed that the Bill in its modified shape is unfortunately not yet before us.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London; or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

PROGRESS AND PROSPECTS OF THE VACCINATION BILL.

THROUGH the courtesy of Lord LYTTELTON, we have received a copy of his amended bill, to which we intend next week to direct attention, in connexion with other important documents which we have received. The bill, in its passage through committee in the House of Lords, has been somewhat improved; but it still remains insufficient for the purpose which it is intended to fulfil—the repression of small-pox through the instrumentality of a national system of vaccination. We have therefore much satisfaction in being able to announce that no immediate attempt is to be made to hurry the measure through the House of Commons; and that some time will be afforded for the profession to express its opinion through the press, through the Branch Societies of our ASSOCIATION, and through such other organized communities of the medical profession as are disposed to assist in the solution of the vaccination question. It is no small satisfaction to have obtained a certain amount of delay; but unless the profession act zealously, it will at the last be saddled with a burden too heavy to be borne.

Unfortunately, the Epidemiological Society, or rather the Small-pox Committee of that body, in place of using its influence to retard the progress of the bill till the whole profession shall have been fairly consulted regarding its principles and its provisions, has limited its exertions to endeavours to improve Lord Lyttelton's measure. This they have attempted by private conferences, and by hurrying their long-promised report, in an avowedly unfinished state, into the hands of the Home Secretary. In these circumstances, it becomes necessary to impress upon Parliament and upon the public, that, however valuable may be the information collected and about to be published by the Epidemiological Society, medical men are not disposed to admit the right of that society, or of any other society, to arbitrate between the profession and the legislature.

The Provincial Medical and Surgical Association, we sub-

mit, has a peculiar right to crave delay till such time as it can give an opinion upon the contemplated measure; seeing that its own report on the subject, published many years ago in its *Transactions*, is the earliest and still one of the best public documents upon the vaccination question. It may in fact be considered as the germ of that more extended inquiry of the Epidemiological Society, which has been brought to so untimely a birth by the appearance of the bill now under discussion. A panic was produced; and the notion was hastily taken up, that to delay legislation till the materials for legislation had been collected, published, and publicly discussed, was impossible; that the passing of a vaccination act during this session was inevitable; and that all the Society could do, was to make the measure as much as possible in accordance with its own views. It is our duty as watchmen—guardians appointed to a watch-tower of the profession—to give the alarm, and, so far as we can, prevent our fellow-practitioners from being taken captive by a *coup de main*. We feel also that it is as much a social as a professional duty to continue earnestly and firmly to crave delay, as we well know that no public good can be gained by passing a vaccination act which does not meet with the general concurrence of the medical profession, by whom its machinery must mainly be worked. Again, medical men have surely some right to be consulted regarding this, and all other public questions, which either concern their science or their social position.

It will be our duty to bring before the ASSOCIATION the valuable Report of the Epidemiological Society, which has been kindly placed at our disposal for that purpose, by Dr. SEATON, the Secretary of the Small-pox Committee. From this and other documents, we hope to enable members of the ASSOCIATION to form correct conclusions upon the whole subject. In the mean time, we would call attention to Mr. Ceely's letter at p. 256; and again implore our colleagues to use every means in their power to obtain DELAY.

INCOME TAX.

BEFORE this number can come before our readers, they will have seen by the newspapers that Mr. Gladstone has asked Parliament to renew the Income Tax, without making any distinction in the rate to be levied on fixed and precarious incomes. As it is universally felt that the tax, though nominally sought to be reimposed for only a limited number of years, is in all probability to be made permanent, the success of the government financial scheme in its integrity, will be felt as a serious evil by our profession. The unequal Income Tax has, however, to sustain the assaults of many influential parties before it can obtain the sanction of the House of Commons, so that we still entertain a slight hope that the prayer of our petitions may find an answer in equity.

ORIGINAL COMMUNICATIONS.

OBSERVATIONS ON THE RECENT PROGRESS OF SURGERY.

By JAMES MILLER, Esq., F.R.C.S. Edin., F.R.S.E., Professor of Surgery in the University of Edinburgh, Surgeon in ordinary to the Queen for Scotland, etc.

(Read before the Medico-Chirurgical Society of Edinburgh, April 6th, 1853.)*

A RETROSPECT of the advance of surgery during the past thirty years may be attempted in two ways; first, by entering upon the details, *seriatim*, of what may seem the most prominent and important improvements in its practice; or, secondly, by classing these improvements into groups; and so taking a more general and comprehensive, and probably safer view of the subject. While the latter plan is preferable, it will, nevertheless, be necessary to adopt both methods, briefly, in the present instance. And first, as to the *catalogue raisonnée*.

1. INJURIES OF THE HEAD. Within the last thirty years, these have become better understood in their nature and risks, and are more successfully treated. The use of the trephine has been limited in ordinary fracture, even with depression; and extended in the case of punctured fractures, even without head symptoms. Both are improvements; operation is withheld, when not absolutely required; operation is performed, when, without it, formidable and fatal evil is inevitable. The use of the instrument is also better understood in cases of compression by blood or pus; and the whole subject has been cleared of some, at least, of the uncertainty and difficulty with which it is almost necessarily connected.

2. AFFECTIONS OF THE EYE. The anatomy, pathology, and therapeutics of the eye, as improved, might well occupy a paper by themselves; and amply testify how what have been termed the specialties of surgical practice should not, and need not, ever give rise to anything in the slightest degree inconsistent with the highest honour and strictest integrity in the conduct of those who practise them. Had not the eye and the ear been carefully and successfully investigated, as they have been, in their disease and cure, by men of science and skill (as Travers, Lawrence, Mackenzie, Dalrymple, and Toynbee) devoting special attention to them, we should have been at this day deprived of much valuable knowledge; not only as affecting diseases of these parts in particular, but intimately connected with the nature and treatment of disease in general. We should have neither seen nor heard much that concerns us, both as patients and practitioners, to see and hear. It is only when the specialties of surgery are cultivated—or rather laid waste—by occupants of unhallowed motive and sinister design, seeking only their own gain, and careless of all other interests beside—it is only then that humanity and our art suffer injury; it is then, and then only, that the stain of quackery, in its most offensive form, attaches to the self-degraded practitioner—whether the specialty be in the eye or in the ear; in the skin or in the spine; in the bladder or in the blood; in the uvula or in the uterus.

The diagnosis and treatment of all the ophthalmiæ, the dealings with cataract, the management of orbital abscess and orbital tumours, might all be dwelt upon. But I content myself with but one example of safe and suitable

* This paper was read in answer to a somewhat similar paper by Mr. Syme, discussion of which had been aborted at the previous meeting of the Society. The author, in his public capacity, felt it to be his duty to comment on that paper, on two grounds:—1. That the Edinburgh Surgical School might not seem to claim for itself almost the entire mass of alleged improvement, introduced into the practice of surgery during the last thirty years. 2. That the mind of the profession, more especially of its junior part, might not be led away, without warning, into the belief that surgery mainly consists of operative or other mechanical details; and that in this direction its main improvement lies. The paper is necessarily fragmentary and otherwise imperfect; and does not pretend to be anything like a full exposition of the entire advance of modern surgery.

The same feeling which constrained the author to read this paper, lays an obligation on him to publish it.

extension of the operative department of surgery, in the application of myotomy for the cure of strabismus—proposed by Stromeyer, first practised by Dieffenbach—an operation liable to abuse when performed either imperfectly or unnecessarily; but nevertheless, in good hands, a decided boon, if not to suffering, at least to squinting humanity.

3. The subject of MYOTOMY is an extensive one. The application of its principle ranges from the orbit to the toe; and, when united with the principle of *subcutaneous wound*, embraces the whole body; constituting a most decided improvement in practical surgery; affording relief at the cost of little pain, less blood, and no permanent injury. In this department the great mass of modern surgeons have been all at work; but the names of those just mentioned probably deserve a special pre-eminence.

4. RHINOPLASTICS have undergone a decided advance; not so much, perhaps, in restoration of the whole organ, as in those partial repairs, of which the part so often stands in need. The best of such operations, for obvious reasons, are those which, by simple incision, subcutaneous or direct, effect the desired repair with little or no detraction from neighbouring parts. One of these deserves special notice—restoration of the columna nasi, as invented and practised by Mr. Liston; effectively restoring the lost portion of the nose, and at the same time decidedly improving the upper lip. The names of Liston and Dieffenbach rank high in rhinoplasty.

5. AUTOPLASTY. Almost the whole of this subject, in its better aspect, is new; including, as already stated, repair by simple incision, as well as by transplantation; the former the higher art of the two. It were endless to particularise its many applications. It may be enough to mention its connexion with loss of the lip. In the practice of the incisional variety, the names of Blasius (1836), Dieffenbach (1838), Serre (1842), and Syme (1847), may warrant special notice.

6. AFFECTIONS OF THE WINDPIPE. Here is a vast store of improvement in pathology, diagnosis, and therapeutics. The more successful application of tracheotomy to oedema glottidis and the extraction of foreign bodies; the proof of its general preferability to laryngotomy, especially in the case of disease; the withholding of all operation in hopeless croup; its occasional use in otherwise fatal laryngismus; and perhaps its palliative power in certain cases of aneurism, are instances. But above all, the true surgical reformer is delighted by the *prevention* of this operation, by means of the simple application of remedial agents to the affected parts; for example, that which has been specially practised and pointed out by Mr. Green. The "swabbing of the windpipe"—liable to miscarry, from either imperfect or excessive introduction of the instrument—is, in skilful and judicious hands, one of the decided improvements of our art: it exhibits simplicity, science, and skill, *versus* bistoury and blood.

7. The JAWS. Here operative surgery has been extended with good effect, in the case of tumour, more especially of the non-malignant kind. Mr. Lizars first proposed excision of the upper jaw; Messrs. Liston and Syme practised bold and successful operations on both the upper and lower jaws; and the Edinburgh school thus occupies a good place in connexion with this operative advance of the art.

8. STAPHYLOGRAPHY. This, at all times a difficult and uncertain operation, has been rendered more simple and sure by Mr. Ferguson; observing what muscles, in their action, strain and separate the parts, and paralyzing these by previous section.

9. The TONSILS, too, have benefited in the matter of evacuation of their abscesses, and removal of their obstinate projecting hypertrophies by simple ablation. Besides, they have been rescued from certain specialists who enjoyed an exclusive reign in that department, as brief as it was undeserved.

10. SPINAL AFFECTIONS have also been delivered, in a great measure, from the hands of some specialists, who, in seeking to do themselves alone good, did others much harm; and these affections are now—thanks to the common sense

of modern surgeons—as well understood and as well treated as any other disease.

11. **MAMMA.** In chronic affections of the female breast, not of a malignant kind, pressure has proved a most valuable agent of cure; more particularly as applied by means of the hydrostatic or aerostatic system of Dr. Arnott.

12. **HYDROTHORAX.** Relief, at least temporary, and it may be a powerful adjuvant to final cure, is obtained by surgical treatment formerly too much neglected. By means of a small trocar and canula, employed with great care so as to avoid the casualty of atmospheric entrance, the fluid is safely withdrawn: respiration is at once freed, and remedial measures have a much better prospect of action in the future. For this useful application of simple surgery we are indebted mainly to Messrs. Cock and Hughes; not forgetting one whom we all esteem and love, Dr. Alison of this city.

13. **GASTROTOMY** includes a great deal of the heroic in modern operative surgery. In the case of ovarian or other tumours, which are slowly enlarging, causing little inconvenience, and not immediately endangering life, it will probably be argued by most prudent men, that to these the extension of surgical operation on the vast scale of the sterno-pubic incision, or even by smaller wound, has been no improvement. But in those cases of complete intestinal obstruction, where the crisis is urgent, death at hand, and agony great; and when by operation it is possible by exposing the seat of obstruction* to afford relief, to protract existence, and perhaps even to obtain a cure—not arriving at such conclusions by mere theory, but by the aid of recorded experience already obtained—then it seems a serious responsibility, under such circumstances, to withhold our surgical aid, difficult, and doubtful, and dangerous though it be. It is a practising of the lowest part of our art, but little removed from the mechanical trade of butchery, no doubt; but, according to our present gifts, it is all that is in our power; and ought it to be withheld? The casual reputation of the surgeon, or even of surgery, must not find a place among the elements for consideration; the question simply is, can life be preserved or protracted, or suffering saved? To attempt relief is a plain but painful duty; the crisis may be neither sought nor shunned. The addition of living and intelligent hours—much more, of days and months—may prove of countless value to a fellow-being.

14. **HERNIA.** The revival of Petit's method of extra-peritoneal section, in many cases of strangulated hernia, has been established mainly by Mr. Luke and others of the London school; rendering the operation at once more simple and more safe. But, better still, in opium and chloroform we have obtained important and additional assistance in the taxis; often preventing resort to operation altogether.

15. **URINARY DISEASE.** It were superfluous to dilate on the vast strides which have been made here in the science of surgery. By the aid of the microscope, and by the advance of pathology, great power is now given to detect the origin of disease, and prevent its cumulative establishment; more especially in the case of urinary concretions. Prevention is better than cure, at any time; and more especially is it better than that peculiar kind of cure which comes by resort to the knife. And here, among many other examples, is found a striking illustration of the great benefit which accrues from the maintenance of an "*entente cordiale*" between the friendly, not rival, powers of surgery and medicine; powers which have but one aim and one science; powers which cannot thrive under estrangement and separation, and whose true prosperity must ever depend on mutual support and incorporation. To tell the truth, were there ever to be a final and complete divorce—a result we cannot contemplate even imaginatively without dismay—it is very plain that surgery must prove the greater sufferer.

16. **LITHOTRIPSY.** Since the first labours of Civiale, in

* The profession will doubtless agree with Mr. Phillips, that operation is warrantable only when there is something like an accurate diagnosis of the site of the obstruction.

1823, just thirty years ago, this mechanical department of surgery has not ceased to make progress. And little doubt remains, in the impartial mind of any one, that such a degree of perfection has been at length obtained in the construction and use of lithotriptic instruments, as to render this operation decidedly preferable to lithotomy, in regard to safety of performance, in not a few cases of stone in the bladder. In the list of operations it certainly stands *minor* to lithotomy; and of two evils we are bound to choose the least. Were this operation, however, or indeed any other, to be practised as a mere specialty, and had recourse to in all cases applying for relief, much harm must inevitably accrue. The surgeon here must be in one sense ambidextrous: equally qualified to cut or to crush; and ready to apply to each case the treatment which to him seems the more suitable.

17. **LITHOTOMY.** Perhaps the principal advance in this has consisted in the operation having been saved from certain innovations which were no improvements, but the contrary; such as, the invention of curious staffs, and the revival of the gorget, or the use of knives simulating the gorget. At the same time, the rules of practice in the received lateral operation have been established and confirmed; for external, limited internal wound; dilatation rather than incision, but incision rather than laceration or bruise; in the prostatic wound, mere notching and thorough division alike reprehensible; the necessity for cutting the inelastic tendinous texture near the prostatic base; the avoidance of bruise and tear in the bladder, as well as in the wound; especial regard to prevent, by all means, infiltration of urine; and last, not least, due preparation of the patient, more especially in regard to his urinary secretion, before the operation is performed. In this good work all surgeons have been labouring; but if one deserves mention over his fellows, it is Liston.*

18. **THE VENEREAL DISEASE.** More than thirty years ago, the venereal disease was treated by mercury with much and melancholy excess. Under the pressure of the many evils which accrued from this, a reaction took place; and, like most other movements of this kind, went too fast and too far. From treating invariably and copiously with mercury, the reactionists came to treat always with none; and evils, though of a lesser kind, emerged in the form of imperfect and protracted cures. In progress of time, the wise and prudent have come to believe in and to seek for that happy medium which is presumed to exist between all extremes, and in which "*tutissimus ibis*". No doubt there are some extremists still, unmoved by experience, and undeterred by ill-success; some out-and-out mercurialists, some non-mercurialists to a grain. But the received practice undoubtedly is—to give no mercury in any form or shape, when experience has shown that the disease can be cured without it—and such cases happily constitute a majority; but at the same time to give mercury, yet with a cautious and economical hand, in those cases in which experience has shown that a cure cannot be obtained satisfactorily, if at all, without it; and such cases do most certainly exist. But, better than all, thanks to the exertions of Ricord and others, the disease may be aborted in its infancy, and "punched out", without any constitutional treatment whatever; again constituting that prevention which is better than all cure. Let me state, however, that the only mention which one mode of prevention of foreign growth deserves here—namely, that by cold-blooded inoculation†—is to enter it into that category which by Mr. Carlyle is somewhat emphatically termed "scoundrelism".

19. **HYDROCELE** has been simplified in its cure by the use of tincture of iodine as an injection; an improvement due to Mr. Ranald Martin, of Indian celebrity.

20. **CIRSOCELE** too, in its radical cure, has been shorn of

* This eminent surgeon was, at one time, too neglectful of the due preparation of his patient.

† Not the test of a suspected venereal sore already existing; not the notion of curing advanced and chronic syphilis by the addition of a new and fresh poison; but the attempt, by introducing modified syphilis into the healthy human frame, to render men, women, and children, subsequently proof against that contagion.

some of its risk; experience having shown that instead of dangerously interfering directly with, and obliterating the veins, by means of needle, or ligature, or cautery, it is enough in some instances to apply gentle but equally adjusted pressure at the groin. This improvement is mainly due to Mr. Curling.

21. **FUNGUS TESTIS.** Modern surgery has done a good work of reclamation here. Sir Benjamin Brodie (1834) had shown that the fungus was part of the testicle, and that instead of being shaved off or dissected out, it ought to be reduced and recovered by cicatrization of the sore. Mr. Curling, (1843) having more plainly demonstrated the projection to consist of the tubular structure, changed by abnormal deposit of a simple inflammatory kind, strongly reprobated excision, and advised that the part should be treated by pressure applied by means of adhesive strap over dossils of lint—with the double view of repressing the fungus under absorption, and at the same time drawing the integument over it towards approximation; thus obtaining cicatrization of the wound, while the testicle gradually regained both its normal bulk, and its normal position in the scrotum.

Mr. Syme (1845) has proposed and practised repression in another way, by cutting off the callous margins which sometimes edge the sore, separating by dissection the integument around, and bringing the line of wound at once into apposition by suture. Should anything like primary union occur, the period of cure will thus be abbreviated; but otherwise, the method by compression of the fungus, with traction of the integument, seems preferable, because obviously more consistent with the general principles of surgery.* And it would seem that advance in this direction, rather than with the knife, is the more sure way to reach perfection in this item of our practical art.

22. **AFFECTIONS OF THE BLADDER** are greatly better understood and better treated within the last thirty years; thanks to the labours of surgeon and physician alike—Brodie, Prout, and a host of others. Among them, Lallemand has certainly done service, by directing attention to the remedial application of nitrate of silver to the posterior part of the urethra, the neck of the bladder, and the bladder itself; as well as by elucidating the nature of a peculiar ailment of undoubted existence and sad importance, but not wholly indicated in the phrase *spermatorrhœa*; and rescuing it from the heretofore almost exclusive grasp of the most false, foetid, and foul, of all quackeries.

23. **STRICTURE OF THE URETHRA.** The use of caustic has been abandoned, as a destructive agent; it is used only, and that very seldom, as a sedative and alterative, in parts specially affected by irritable excitement. The simple use of the bougie, both by perforation and pressure, has become better understood and more highly appreciated. The medical treatment of the urine and its organs, greatly advanced in perspicuity and precision, has proved a most powerful auxiliary to surgical manipulation. For the worst class of strictures, which will not yield to aught else, the knife is still reserved as a last resort; and in those which are at all permeable, though it may be with much difficulty, Mr. Syme has established an improved principle of operation; dividing the stricture throughout its whole extent, on a grooved staff, by direct incision; the cure to be afterwards completed by use of the bougie in the ordinary way. In these several ways, the treatment of this disease has made good progress; but, alas! we cannot yet say that its cure is perfect. Surgery will not rest satisfied, we trust, till the knife has been banished, almost if not altogether, from this portion of its practice; and even the bougie restrained within narrower limits than it is. To medicine and surgery conjoined, the obstacles surely cannot prove insuperable, which stand in the way of removal by absorption of the redundant non-malignant deposits, and consequent changes

of structure, which occur in the course of this mucous canal.*

24. **ANEURISM.** The Hunterian operation has been simplified and improved, by freeing the incision from all tear or bruise; by isolating the arterial coats thoroughly, but only at the point of deligation; and by carefully avoiding all injury to the vein, and every other contiguous texture whatever. But from the Dublin school has emanated a scientific and successful revival of pressure, applied to aneurisms which are external and accessible, founded on the principles of the Hunterian operation, and carrying out those principles more thoroughly than even did the ligature. With this—the ligature—intromission with a sound portion of the artery could not always be secured, even in the case of popliteal tumour; but modern pressure escapes this difficulty by proving successful to cure the aneurism, while it is so slight in its application as not to be likely to injure the arterial or venous coats. The theory is beyond cavil; its successful practice has been demonstrated. The authentic records of surgery now show that such pressure, well applied, cures certain external aneurisms, on the average, as rapidly, as easily, much more safely, and at least as permanently, as does the ligature.† Under such circumstances, the conclusion seems inevitable, that the surgeon who shuts his eyes to this improvement

* It is not meant that the use of instruments may be expected altogether to cease; but only that in the management of this disease the surgeon shall become less exclusively dependent on them than he is at present; deriving more and more doebstruent power from non-mechanical means.

† That compression is an *effectual* cure for aneurism, is proved by the fact that, during eight years, the ligature has only been used three times in Dublin, either in hospital or private practice, in two of these cases the aneurism being traumatic. During this period, compression has been employed in 39 cases. In 30 of them, a perfect and complete cure was the result. In 1, compression was discontinued, and the tumour did not increase in size. In 2, the ligature was used successfully. In 3, amputation was necessary, the patient surviving in each instance. Three patients died; 1 from erysipelas, and 2 from disease of the heart. It is quite clear, from the details of the cases in which amputation became necessary, that the ligature would not have lessened the necessity for removal of the limb; but, on the other hand, would have almost certainly induced gangrene, and thus lessened the probability of saving the patient's life. The death from erysipelas occurred during a prevalence of this disease in the hospital, galvano-puncture having been employed, and the patient himself having unduly increased the amount of pressure.

The average duration of treatment in these cases, was twenty-five days. The average of the eight most favourable cases was only twenty-eight hours. In one case, seven hours and a half only were required for total solidification of the contents of the sac. There can be no doubt that, from the admission of a patient to the time he leaves the hospital, after the employment of the ligature, a longer average stay than twenty-five days takes place, and that a very speedy cure cannot be hoped for.

Statistical returns of the success of the ligature give the following results:

"In Dr. Crisp's work (*Diseases of the Blood-vessels*, p. 235 *et seq.* 9) are detailed the particulars of 188 cases, where the vessel was secured for popliteal or femoral aneurism. Of these—

Died from the effects of the operation	35
Recovered after suffering subsequent amputation	11
Recovered after sloughing of the sac	9
Recovered after mortification of the toes	1
Recovered after sloughing of the integuments	1
Total	67

So that more than the fourth of these cases either terminated fatally, or were maimed for the rest of life.

"Mr. Phillips's experience and researches are the next to be considered. They are thus quoted by Mr. Storks (*Lancet*, May 1846):—"Mr. Phillips collected 171 cases of aneurism affecting the lower arteries, which were submitted to the Hunterian operation. Of these cases, 57 (or exactly 1 in 3) were unsuccessful, in which all the patients except 2 died, not of the disease, but of the operation. Amongst the successful cases, secondary hæmorrhage took place 15 times. 50 of these cases required ligature of the femoral artery, 39 of which were unsuccessful; thus giving a mortality of 2 in 3 in the artery most frequently subjected to the operation."

"Mr. Norris (*American Journal of Medical Science*, October 1849) gives a fuller report, his table embracing 177 instances (135 of popliteal and 22 of femoral aneurism) where the operation was performed. He gives the surgeon's name, the sex and age, situation of disease, its duration, periods when each operation was performed, when the ligature came away (if fatal), the date and cause of death, with reference as to where the particulars of each case are recorded. There is, then, no getting behind this collection, no stating, in general terms, that statistics are wrong, and cannot be relied on. If truth is spoken in the first published details, it is re-echoed in Mr. Norris's table.

"He gives, I say, 177 cases, of which—

Died from the effects of the operation	38
Recovered after subsequent amputation	6
Recovered after suppuration of the sac	10
Recovered after gangrene of the foot	2
Total	56

So that nearly one out of every 3 cases operated upon, either terminated fatally, or were, to a certain extent, maimed for the remainder of their lives." (pp. 148-50.)—*British and Foreign Medico-Chirurgical Review*, October 1851, pages 470-471.

* A wound inflamed and suppurating, having failed to adhere, tends to gape, and should be allowed to do so—stitches, with this object, being cut away. Here, however, under such circumstances, the stitches must be maintained, on account of their mechanical effect alone; otherwise the fungus would again protrude, and the parts resume the *status quo*.

alike of his science and art, and refuses to practise it, incurs a serious responsibility each time he applies his knife and ligature for the cure of an external aneurism to whose treatment a more gentle, more scientific, and safer means, is proved to be applicable; the more so, when it is further observed, that, should compression fail, the way is still left open to the treatment by deligation on at least as favourable terms as if compression had not been employed. The liberal and enlightened surgeon will at all times cheerfully acknowledge that the science which saves resort to the knife is ever a true improvement; and that when, in the successful cure of aneurism, he compares Hunterian pressure with Hunterian ligature, the former is the higher art of the two.*

25. THE AFFECTIONS OF THE RECTUM, at one time the almost undisputed domain of quackery and imposture, have been restored to science and common sense—a good work due to many good surgeons; among others, to Boyer, Brodie, Dupuytren, Ribes, and Syme. It is enough to mention the detection of the internal aperture in fistula, and the simplifying of the operation in that disease; the pathology and treatment of hæmorrhoids, external and internal; the detection and management of fissure and ulcer; the dilatation of simple stricture; the introduction of O'Beirne's defæcating tube, capable of affording great relief in many cases of peril and distress; and the ignoring of all long bougies adapted for the removal of the promontory of the sacrum, or at least intended only for the benefit of the miserable specialist, whether unprincipled or uninformed, who certainly (whatever his poor, deluded, hypochondriac patient might do) could never lay claim, in any sense, to the "*mens conecia recti*".

But it were alike ungenerous and unjust to withhold due meed of praise from the sister art of medicine, in the improved treatment of affections of the rectum. She has taught us that congestions occur here, as elsewhere, from causes situated remotely from the parts affected, and are to be treated accordingly; that irritable ulcers, abrasions, and fissures, are invariably connected with, and almost always dependent on, disorder of the general system, and that, when they occur in the rectum, they are to be treated in conformity with that general law; that spasms of muscles here, as in other mucous canals, are often dependent solely on irritation in some other and perhaps distant part, and that such spasms are often best removed by removal of this irritation, irrespective of all local treatment whatever; that in all cases the most successful local treatment will prove but temporary and deceptive, if not associated with careful attention to the *prima via* and general health; and that it is a limited *half-surgery*, worthy not of modern, but of ancient times, which rests content, here or anywhere else in man's living frame, with the mere work of the hands.†

26. FRACTURES. The nature of the process of reunion has certainly become better understood; and the restless ingenuity of man has not been idle in inventing mechanical means to assist it. Of the many varieties of modern splints, however, we need not speak, save to felicitate ourselves that, among so many, there must be surely some improvements. But the system of M. Seutin—the immobile apparatus, or starch bandaging—may be safely set down as a step taken in the right direction; such apparatus, when applied in the proper time and way, saving the practitioner much trouble, the patient much annoyance, and certainly contributing to rapidity and certainty and perfection of cure. Ununited fracture has had a more definite treatment assigned to it: in the recent and slighter cases, the starch and immobile apparatus; failing that, subcutaneous puncture; that failing, the seton, or Dieffenbach's pegs.

* Of course, no one supposes that pressure is ever to supersede ligature altogether in aneurism; but only in certain cases. As in some cases lithotomy is preferable to lithotomy, resection to amputation, etc.

† Fissure and ulcer of the anus often require the use of the knife, along with notwithstanding constitutional treatment. In not a few cases of these affections, and in many more of anal spasm, ordinary treatment will wholly supersede operation. In no case whatever can immunity from return be expected, unless constitutional and local treatment have been conjoined. To cut the sphincter and merely because it is affected by spasm, is as irrational as to open the windpipe in every case of laryngismus.

27. DISLOCATIONS. In the examination of injury, what surgeon has not constant cause of thankfulness to anaesthesia for facility and accuracy of diagnosis, as well as for vast facility and safety in effecting reduction? The best auxiliary in this task is on all hands admitted to be chloroform.

28. LOOSE CARTILAGES IN JOINTS. By applying the principle of subcutaneous section, at the instance of Messrs. Syme and Goyrand, these and other foreign matters have found a safer mode of exit than was wont to be; and the knee-joint profits specially by this. The operation, as first practised, has been subsequently improved; and it is likely that in not a few cases even this improved operation may be superseded by a yet simpler procedure—fixing the cartilage at a safe part of the joint, with a view to its being first incorporated, and perhaps afterwards absorbed, in the permanent locality. This latter principle of treatment was first proposed by a writer on systematic surgery, in 1844; and has lately been adopted and modified by Mr. Syme.

29. AMPUTATION is a necessary evil in surgery; it can never be wholly superseded; but its practice has of late years been much improved in many ways, as regards the hæmodynamic compression, the formation of the incisions, deligation of the vessels, and dressing of the wound. In this good work, the name of Mr. Liston stands pre-eminent.

Revival of amputation at the ankle, and the making of a much better cushion there for the ends of the bones, is a decided and important improvement, due to Mr. Syme.

30. RESECTION OF JOINTS. To the same surgeon we are indebted for the revival of this operation, more especially in connexion with the elbow and shoulder joints. Resection, when successful, is greatly preferable to amputation, as it entails less risk to life, and leaves the limb but little impaired in function.

31. DISEASES OF JOINTS AND BONES. Infinitely superior to either resection or amputation, is that improved knowledge and treatment of joints and bones which averts or arrests disease, and obtains a cure without recourse to operative surgery at all, whether of the conservative or destructive kind. Many a limb which, thirty years ago, would have been doomed to amputation, is saved by resection of its joint; and many a limb which, ten or twenty years ago, would have been saved only by resection, is now saved by the combined appliances of medicine and surgery, without resort to any knife work whatever. Conspicuous in this good work—because its founder—must ever remain the name of Brodie. (1818, 1st ed.)

32. TREATMENT OF WOUNDS AND SORES. Here very decided advance has taken place, in greater simplicity and efficiency of management; superseding cumbrous greasy poultices by simple water-dressing—ointments by lotions—sutures by attention to position, and the use of tenacious, non-irritating straps; discarding sponges as fomites of evil; limiting greatly the use of cauteries, more especially the actual; never treating a disease merely by its name, nor employing any general panacea;* and by constant care of the system, both as to medicine and hygiene, averting or mitigating those many inflammatory evils which prove such sworn foes to safety and speed of cure. In the Edinburgh school, it need not be said that Liston's name stands foremost in this practical reform.

33. TUMOURS. The pathology of these growths has been wholly recast; thanks not to surgery alone. Alas! however, the cure has not kept pace with the knowledge of the disease. The majority of all tumours are remediable only by the knife; and the majority of malignant tumours refuse to obey even this stern power. It will be true improvement when excision proves more effectual than it is; it will be a better improvement still, should the knife be superseded by simple discussion. In that direction lies the true advancement of surgery.

* A sore is liable to shift its character suddenly and often; and the treatment requires to be altered accordingly. Further, the "varicose ulcer" may and does include every kind of sore—healthy, weak, indolent, irritable, etc. And the assertion that for the "varicose ulcer," any form of lotion, ointment, or other application, is an invariable cure, is calculated to retard surgery.

Even now, it is something to know, better than we did, what tumours admit of discussion under our present gifts, and what do not; what tumours are curable in any way, and what are in all ways incurable. To attempt the impossible in either class of cases, must ever prove fertile of unmitigated evil.

34. GANGRENA SENILIS is better managed than in the days of Pott. He saw the evil of stimulant constitutional treatment, yet scarcely avoided it. Marjolin, more alarmed, flew to decided antiphlogistics (1824); Broussais (1827) adopted that extreme still more thoroughly; and Dupuytren (1833) still, for a time at least, was over-antiphlogistic. Then, however, the oscillations between the two extremes of heroic stimulants and heroic antiphlogistics settled down; and the pendulum has for some time rested at or near the *juste milieu*. In 1835, the principles and practice of the modern day in this disease were publicly taught and recorded by Mr. Liston.* In 1841, the same subject was contributed to by Mr. Syme, but with probably too near an approach to the antiphlogistic stringency.† The difficulty obviously is, to feed the patient and yet starve the disease (*inflammatio debilis*); to cure the disease, and yet not kill the patient.

Such are some only of the improvements introduced into surgery of late years, considered in detail. In connexion with these, but few names have been specially mentioned, simply because it is most difficult for an impartial inquirer to determine to what individual men the improvements are really due. Surgeons are one vast company, all travelling over the same wide field, at different times, with different strength and speed, and, it may be, sometimes by somewhat different ways. Some men there are, each specially bent on discovery, with downward head and limited vision, thinking little either of their present neighbours or of those who have gone before, and with mind and eye intent only on their own limited track; and some of these may often cry "Eureka!" little knowing that the same thing had already been discovered by a previous traveller on the self-same path: or, perhaps, that while they lit on it, other eyes and hands had at the same time also found it. The truth is, the hunters are in packs, whether they will or no. There is no room, in the present day, for an exclusive and solitary following. Discovery, improvement, advance, in the main, are due to surgery rather than to schools; to surgeons rather than to any generation.

Time permits me to touch but briefly on the second and more important part of the subject: viz., to classify the modern improvements, and embrace them in a more general view.

I. MEDICAL TREATMENT OF SURGICAL DISEASE. I would venture to state, as the greatest improvement, that which has united the sister sciences of surgery and medicine more closely and inseparably than ever they were before; the two combined constituting the best specimen of "rational medicine" that humanity has ever known. As already observed, their science is one and the same; it is their practice only that differs. The constitutional, or medical, treatment of wounds and sores, of bones and joints, of urinary affections, of spasms and pains, etc., has done more to advance true surgery in our day than any other agency whatever. Disease is more accurately and easily detected, and is more speedily subdued; texture is better saved, function is more speedily and thoroughly restored; a more complete victory is won, while the frame is less shaken in the struggle; and the opprobria of our art—its operations—are in consequence being limited within an ever narrowing circle.

With this may be classed a better knowledge of, and a more confiding trust in the reparative powers inherent to the frame—the *vis medicatrix nature*: the surgeon having come to know, better than ever he did before, that it is often his cue to stand by, and see the part or system evolve its own cure.

II. THE INTRODUCTION OF ANÆSTHESIA has revolutionized our operative department, and given a bright page to the history of modern surgery. For anæsthesia we stand indebted to our transatlantic brethren; and it needs not to be stated here to whom we owe the use of chloroform, as yet the best anæsthetic. The detection of injuries; the reduction of fractures, dislocations, and herniæ, the absence of pain, and the increased power of endurance during operations—these words all call up a host of thoughts and experiences in the minds of practical men, testifying to the great value of this discovery. It has been a progress in the right direction; often preventing operation, and mitigating its horrors when inevitable.

III. THE TREATMENT OF ANEURISM BY COMPRESSION, with all efforts of a similar kind, constitutes also a sound step in advance; doing, by means of science, and in comparative safety, what the rough art of the knife does more rudely, and with comparative risk.

IV. MYOTOMY, and SUBCUTANEOUS SECTION in general, have contributed much to the relief of suffering and deformity, at the cost of little pain or danger. Inflammation, hæmorrhage, and the other risks of open wounds, having been avoided, joints have been supplied, eyes liberated, necks straightened, foreign bodies extruded, noxious fluids drained away, feet and legs restored to form and function; and all without danger or loss.

V. RESECTION OF JOINTS, as already stated, has saved many a limb, and perhaps not a few lives also, which otherwise must have yielded to amputation.

VI. THE MAJING OPERATIONS, such as amputations, dissections of tumours, and excision of bones, have been simplified in their performance, and, to some extent, made more safe. Besides, they have been extended to the remedy of some forms of disease previously rated incurable; and this, though the least of modern improvements, and hanging on the very outskirts of true advance, is still to be gratefully acknowledged. *Remedium anceps et durum, melius tamen quam nullum.*

To sum up in more general terms:—

1. The greatest improvement has undoubtedly been that application of the general principles of science common to the healing art, whereby all operative interference has been averted.

2. The use of anæsthesia, when operation has become inevitable, deprives it of all immediate pain, as well as of much of its formidable shock.

3. Minor operations have been successfully substituted for major ones; a very capital improvement. And

4. The greater operations, while performed more seldom, are done better.

In conclusion, may I be permitted to state wherein true surgical improvement and advance seem to consist, and wherein they do not? Not in extending the field of operation (save only in those extreme cases which, according to our present gifts of healing, are otherwise incurable); not in devoting the sole energies of surgery to its handicraft and mechanical details, an art in some respects but little removed from that of the mere tradesman; not in seeking to do with the knife what can be at least as well done without it. But in cultivating Surgery's head rather than her hands; in prosecuting, more and more successfully, that general knowledge, common to surgery and medicine, whereby the diseased part is to be cured, and not cut, far less cut out or cut away; in fulfilling the great mission given to our god-like profession—"Assuage suffering, heal injury, remove deformity, but with the slightest possible cost of flesh, and blood, and life; and, by every reasonable and available means which ingenuity can invent, and experience warrant, avert death." This last duty, while humanity lasts, must no doubt entail a certain amount of knife-work, and that even of the baser sort, as in removal of hopelessly crushed and mangled limbs. But let us ever remember that, in general, rather than cut the worse than Gordian knot of disease, it is better patiently to unravel the tangled cord,

* Lancet, March 14th, 1835, p. 850.

† "Enforcing a strictly vegetable diet".... "This starving plan may appear rather startling"—Syme, *Contributions, etc., to Surgery*, p. 6.

leaving its several strands entire. That diplomacy which, though perhaps prolonged and fluctuating, yet terminates in peace, is better far, and shows a higher skill, than that which, hot and gusty, at once takes up the sword. Let us remember that there is much truth in the quaint Hindoo apothegm—"He that knows herbs, is a man; he who knows mercury, is a god; but he who knows the knife alone, is a demon." Let us seek to acquire the utmost dexterity and tact in all operative and other mechanical details of surgery; let us be ready at a moment's warning, when stern necessity demands, to undertake the most fearful and formidable knife-work, in that calmness which sense of duty, mingled with sense of power, can alone bestow. But let there be no ground for any one pointing to surgery as some Shylock, ever whetting her weapon, and demanding "the pound of flesh" which is "written in the bond". Let her show rather Portia's spirit, seeking mercy, and, by some easier way, saving the victim from all claims of the stern creditor Disease. Let no one have ground to say that surgery is again to become a thing of mere handicraft in its peculiar and special phase, and that it may once more be annexed to physica as little other than a menial serving-man. Let us draw more close the bonds—not servile, but friendly—which unite the two branches of our common profession, and arm in arm, with kindred spirit and kindred aim, go forth as brethren, and dwell together in unity.

Edinburgh, April 1858.

CLINICAL NOTES ON RHEUMATISM.

By JOSEPH BULLAR, M.D., Physician to the Royal South Hants Infirmary.

THE most severe acute disease admitted into the wards of this Infirmary, during the winter, is rheumatic fever, and its usual serious complication is the inflammation of the pericardium or internal lining of the heart. During the winter of 1851-2 the heart was affected in most of the cases admitted; but this winter (1852-3) the lungs, and not the heart, have been affected, and in a sufficient number of cases to shew the epidemic constitution of the season.

CASE I. December 30th. Ann B., aged 27, a domestic servant, had been indisposed for two months with cold, cough, and pains in her legs, but was not laid up from work until two days before admission, when she was seized with rheumatic fever. On admission she had severe pain, swelling, and redness of the joints of the elbows, wrists, knees, and ankles; she had a rapid full pulse; a loaded tongue, dry, and brown in the centre; profuse acid sweats; and cough, with quickness of breathing. There were fine crepitating *râles* over the posterior surface of the left lung, the lower lobe of which was dull on percussion, and did not expand fully; this passed on to complete hepatization. The expectoration, which was at first scanty and rusty, became copious, muco-purulent, and greenish, as if tinged with bile. The secretions from the bowels were drab-coloured and offensive.

At first she was freely purged with saline purgatives with some relief. On the sixth day of the disease she was ordered two grains of calomel, with one grain of opium, at bedtime, and two drachms of Rochelle salts in the morning; and to be repeated, if necessary, so as to insure at least two liquid stools daily. On the tenth day, the dose of calomel and opium was diminished one half, which she continued for twelve nights, with her saline purgative in the morning. This gave her quiet nights; and the symptoms gradually improved; but although the joints were well, yet, as the tongue was still coated, the lower lobe of the left lung not pervious to air, and the secretions still light and offensive, a pill, containing one grain of hydrargyrum cum creta, with a grain of Dover's powder, and three grains of rhubarb, was ordered to be taken every night. It was continued for ten nights; when, as the tongue became clean, the secretions natural, and the lung permeable to air, it was discontinued; and in a week she was discharged well.

Although the whole of the left lung was inflamed, and the lower lobe completely hepatized, she was convalescent in a month. She was strong, rather plethoric, but of a good constitution. The state of the tongue, and the offensive light-coloured stools, indicated the necessity of unloading the liver; and as the general symptoms improved under this treatment, no specific remedies were employed for the pulmonary complication.

CASE II. Samuel D., aged 32, a carpenter, had had rheumatic fever twice previously; once when 18, when he was confined six months; and a second time, for two months, six years ago. He was admitted on January 18th. He had been ill a fortnight before admission, and confined to his bed five days. He looked pallid and debilitated; he was helpless, as all his large joints were swollen and painful. His pulse was rapid; his tongue dry and brown; and he had no sleep. The day after admission, cough came on, with shortness of breath and rusty expectoration; and on examination, the right lung was found inflamed. In the upper lobes, crepitating *râles* were heard posteriorly, and there was dullness on percussion over the lower lobe, which soon became hepatized. The treatment consisted in two grains of calomel and one grain of opium at night; which, after a few doses, was diminished to half the quantity; and a draught with two drachms of sulphate of magnesia and half a drachm of carbonate of magnesia in the morning, repeated in the afternoon, if necessary, to secure a free evacuation of the bowels. The stools were at first lumpy, light-coloured, and offensive; but the medicine brought away copious bilious stools, and the tongue became moist.

He found much relief from his harassing cough from this mixture:—

Rx. Vini antimonii tartratis ʒj.

—ipecacuanhæ ʒj.

Syrupi papaveris ʒij.

Oxymellis scillæ ʒij.

Liquor ammoniæ acetatis ʒij.

Misturæ camphoræ ad ʒviij. M.

Fiat mistura, cujus sumat partem sextam ter quotidie.

The calomel and opium at night, and the saline purgative, were continued for three weeks, with gradual improvement of all his symptoms. In a month he was convalescent, but was weak, with a tendency to pain and swelling of his hands. He improved under quinine, and five weeks after admission was discharged. The hepatized lung was quite permeable to air, expanding fully; but he still had some cough.

CASE III. February 3rd. Thomas H., a strong, vigorous young man, aged 23, was admitted under Dr. Oke. Three weeks before, he had caught cold from exposure to wet, with cough, hoarseness, and loss of voice; followed in a week by rheumatic inflammation of his knees, ankles, and elbows, pain in the back, great dullness, and no sleep. On admission, besides the usual symptoms of acute rheumatic fever, he had pneumonia of his left lung with complete hepatization of the lower lobe. The following pills were ordered:—

Rx. Hydrargyri chloridi gr. j.

Extracti aloës aquosi gr. j.

Extracti colchici acetici gr. ʒ

Pulveris opii gr. ʒ. M.

Fiat pilula ter die sumenda.

He continued this for a week; and it was then taken twice a-day for another week, and then once for a few days. It acted freely on his bowels, with marked and gradual improvement both of the rheumatic and lung symptoms. On the 14th he left his bed. The lower lobe was still impermeable to air, but it was gradually restored to a healthy state, and on February 21st he was discharged.

In the following case the only internal organ affected was the lungs, though it did not run into hepatization.

CASE IV. Jan. 29th. James P., aged 33, a waiter, had been confined to his bed with rheumatic fever a fortnight before admission. It came on with severe shivering and much pain in the larger joints, so that he could not bear the bedclothes to touch him; he had sleepless nights, and some cough. On admission, he was so weak and helpless as

to be unable to sit up in bed: all the large joints were painful and somewhat swollen, and the ankle joints were also red. The tongue was dry and brown; he had no quickness of breathing, but cough, with expectoration of tenacious mucus sticking to the vessel, and of the rusty pneumonic colour; but there was neither the fine crepitation nor dulness on percussion; and the only stethoscopic symptoms were moist *râles* in the back parts of both lungs. Two grains of calomel and one of opium at bedtime, with half-an-ounce of castor oil in the morning, for three days, brought away copious foetid, light-coloured stools, with general relief. The calomel and opium were then diminished one-half, and a draught with two drachms of sulphate of magnesia and half-a-drachm of carbonate of magnesia given in the morning. The tongue soon became moist and cleaner, and all the symptoms gradually improved. He left the infirmary on the 20th of February, convalescent.

CASE V. During this period there was another case which might belong to the same class. The patient was a young woman, who had been for some time in delicate health, and her prominent symptoms were severe pains in her limbs and back, which were aggravated at night, and which seemed to be of a rheumatic character. On Dec. 24th, she became feverish with some cough; and on examining the chest on the 27th, the greater part of the right lung was found to be dull and impermeable to air, with true crepitating *râles* above it. Her convalescence was slow, but her treatment did not require any better means.

REMARKS. In neither of these cases was there any affection of the heart; and as the hepatization of the lung was recovered from, it must be considered a fortunate circumstance that the effusion was poured into the substance of the lungs rather than into the pericardium, or upon and within the heart. One advantage the lungs must possess is in the relief which copious expectoration must afford; so different from a shut sac, where absorption alone can remove the effusion. In one of these cases, where the patient was plethoric and young, the expectoration of mucus, which looked green with bile, was very profuse, and must have greatly assisted in relieving the over-loaded system. The chemistry of expectoration from the lungs, and especially the recent valuable researches of Dr. Beale on the expectoration in pneumonia, in which he has shown that the chlorides which are deficient in the urine during pneumonia, are present in great quantity in the sputa, are in accordance with the rational notion that copious expectorations from mucous membranes are channels by which waste and superfluous matter is got rid of, and it is a branch of investigation very promising of results, and most worthy the attention of chemical physicians. The treatment in these cases was tried on the principle that the system had been over-loaded, and that nature required assistance in her attempts to relieve herself; and as the liver is one of the chief organs of such eliminations, the means were essentially purgative—a moderate dose of calomel and opium at night, and a saline purgative in the morning, so as to insure at least two loose stools. At first, two grains of calomel and one of opium at bedtime, reduced in a few nights to half that quantity, with two drachms of sulphate of magnesia and half a drachm of carbonate of magnesia in the morning, and repeated in the afternoon if necessary, and continued until the symptoms yielded and the tongue became clean, were the chief remedies. When the cough was troublesome, a mixture with ten minims each of antimonial and ipecacuanha wine, with half a drachm each of syrup of poppies and oxymel of squills every five hours, gave relief; and strict farinaceous diet, without any broths, was enjoined, with tea and lemonade as drink. In all the cases, on admission the tongue was so loaded as clearly to indicate the necessity of aperients. On this simple plan these cases proceeded satisfactorily; neither became at all unmanageable; nor did it seem necessary to treat the pneumonia otherwise than as a symptom of the rheumatic fever.

Southampton, April 1853.

CASES ILLUSTRATING THE EFFECTS OF THE WARM BATH IN ASPHYXIA: WITH REMARKS.

By JOSEPH C. S. JENNINGS, Esq.

(Read before the Bath and Bristol Branch, March 24th, 1853.)

CASE I. DROWNING: RESUSCITATION AFTER TWENTY MINUTES' IMMERSION: WARM BATH: DEATH.

A. A., aged 80, threw herself into the river Avon, the water reaching to her waist. She was carried by a rapid current three hundred yards down the stream, and round several sharp curves, rolling over in her course; and finally sank in a deep hole. She was then carried under water a distance of forty yards, where her further progress was arrested by a tree growing in the middle of the river, in which her clothes were entangled; her head and body still remaining submersed nearly on the bottom.

I was present when the body was taken out. The time of complete submersion had been at least twenty minutes. The countenance was livid, and the tongue protruded from the mouth. I immediately applied my mouth to hers, but with some difficulty, from the circumstance of the jaws being toothless, and the muscles thoroughly relaxed. However, holding the nose with one hand, and compressing the thorax with the other, I began to inflate the lungs, and persevered for ten minutes, when I was relieved by the arrival of a strong man, to whom I relinquished the task of inflation, while I went for a galvanic battery. I previously directed the body to be stripped of wet clothes, enveloped in four blankets, and laid on a board, to avoid damp from the earth. I also directed frictions to be applied. On my return, I found the lips quivering, and feeble attempts at respiration. I immediately applied one wire to the precordial region, and the other to the head and neck, in the course of the pneumogastric. The heart began to act, and respiration was, in the course of a minute, thoroughly established. The patient speedily began to groan loudly, and continued to do so for four hours, during which time I continued the galvanism. At the end of that period, she was still unable to speak, there being almost complete insensibility; the power of swallowing, had, however, returned, and she took half a glass of brandy. She was then carried home (nearly a mile), groaning loudly all the while; and placed in a warm bed. Hot bottles were applied to the surface of the body; but, as it still continued cold, and the patient comatose, I directed a warm bath to be prepared, which was speedily done. After being placed in it for three minutes, she looked about with great anxiety of countenance, and attempted to raise herself. I was just about to speak to her, when I perceived that she convulsively grasped her chest with both hands, and then fell forward in a state of syncope. I immediately lifted her on the bed; but she only gasped a few times. I then applied the wires, but without avail; and found it impossible to inflate the lungs, although I introduced a flexible tube into the trachea.

I have introduced this case to the notice of the Association, as I am anxious to learn whether galvanism is usually resorted to at receiving houses in such cases, and with what benefit; also whether the warm bath may not frequently, especially at such an advanced age, produce syncope, and so be likely to prove rather injurious than beneficial.

CASE II. ASPHYXIA FROM CARBONIC ACID GAS.

Aaron Hillier, aged 60, accompanied by Eli Knee, aged 22, descended into an ice-house, twelve feet in depth. Hillier was going down the ladder first, with a lighted candle; but had not proceeded many steps before the light was extinguished. He returned, and, having re-lighted the candle, again attempted to descend; but again the light was extinguished. Ignorant of the cause, he procured another light, and a third time went down. This time he reached the bottom, when the lantern was heard to fall. Knee then went down, followed by two others, all three holding each other by the hands. On reaching the bottom of the ladder, Knee became insensible; and it was with great difficulty that he could be brought up.

water was then thrown into the house; but Hillier was not brought up for nearly an hour.

On my arrival, about half an hour after Knee had been extricated, I found him respiring feebly, much convulsed, and totally insensible. After applying the electro-galvanic current, at intervals, for half an hour, he was able to articulate, but remained insensible to what was going on around him for a long time. At length he recovered.

As soon as Hillier was brought up, I inflated the lungs, and applied electro-galvanism for an hour and a half. Frictions and hot blankets were also resorted to. The surface was very cold, in consequence of the large quantity of water which had been thrown upon him while lying on the ice. Respiration and pulsation at the wrist had both ceased; but, after continuing the current for the time above stated, the jugular vessels became much distended, and the face livid. I then opened the jugular vein, and about half a pint of blood flowed freely. As the body and extremities remained cold, and no attempt at respiration could be perceived, I placed him in a warm bath, but found, within two or three minutes, that galvanism ceased to produce even convulsive action, and that any further attempts to restore animation were useless.

REMARKS. As regards the first case, there can be no reasonable doubt as to the length of time during which the woman was totally immersed. A boy, who saw her walk into the river, ran by the side exhorting her to endeavour to get out, until he saw her finally sink in deep water. He then ran a mile to give the alarm; and an equal portion of time, necessarily occupied by him in so doing, must have been spent by those who came to render assistance. It is to be feared that many lives are sacrificed, under the supposition that the period of immersion has been too long for any efforts to be successful.

I found it requisite to continue the galvanism as above described, as the respiration became feeble and almost imperceptible whenever it was discontinued. While the patient was being carried home—a distance of a mile—and after she was placed in bed, she continued to groan loudly without the assistance of the battery; but the jugulars were much distended, and the lungs and brain probably congested from the long immersion and cold weather.

The ice-house had been opened for some time the day previously to the accident which befel the two men. Might not the carbonic acid have been generated by the oxygen supplied to the carbon of the decomposing and fermenting straw and faggots, upon which the ice was placed? The same parties had been down on the preceding day, when there was no foul air. If this be correct, such accidents may be prevented for the future.

We constantly find, in medical works, or in charts containing lists of remedies in cases of accident or poisoning, the warm bath recommended as of great value. We must, however, remember that nothing is to be more dreaded than syncope; for then the functions of respiration and circulation are almost or altogether suspended, even although previously thoroughly established. In cases, then, of asphyxia, or (speaking more properly) of apparent death by apnoea, frictions and external dry warmth will restore the excitability of the reflex functions; but, after restoring, we may again exhaust by the continued application of one stimulant, even warmth. But by employing, at intervals, electricity, warmth, and other stimulants, we shall excite the reflex function without exhausting or destroying it.

The cold douche also, if employed immediately after the poor man had been exposed to the carbonic acid, might have saved him by exciting the reflex function; particularly as each bucketful carried with it a current of atmospheric air, which would have been inhaled with each sudden inspiration.

The battery used in the case of drowning was a powerful four-celled Daniell's (kindly lent by W. H. Fox Talbot, Esq., of Lacock Abbey), with a large coil and regulator, and in good working order. The other used was Smee's, by Messrs. Horne and Co., and was such as is commonly employed for medical purposes.

Abbey House, Malmesbury, Wiltshire, March 1853.

CASE OF MALIGNANT DISEASE OF OVARIES: SUDDEN DEATH.

By GEORGE KING, Esq.

CASE. Miss H., aged 47, a dressmaker, single, of cachectic diathesis, applied to me on 27th November 1852.

A short time previously, she had discovered a swelling in the left iliac region, which she assured me she had only very recently noticed. On examination, I found a tumour of considerable size occupying the greater part of the iliac region of the left side; it was circumscribed, and gave the sensation of indistinct fluctuation. She had experienced very little pain or inconvenience, nor was the tumour tender.

On examination *per vaginam*, the os and cervix uteri were found healthy, and the uterus itself appeared of normal size. The catheter entered the bladder obliquely, but no urine was found there. The catamenia had flowed with tolerable regularity until quite recently, and her general health had been tolerably good.

On inquiry, I found that the bowels had been somewhat confined; and thinking there might be some fecal accumulation, she was moderately purged for several days without diminishing the tumour. At the end of a week, there being some tenderness over the tumour, leeches were applied several times, and calomel with opium given. When the inflammation had subsided, iodide of potassium was administered internally, and the unguentum iodinii comp. applied over the surface of the tumour.

Having persevered in this treatment for some time without any benefit, and feeling that the case was one of considerable obscurity, I urged her to see Mr. Norman, of Bath. He quite agreed with me as to the obscurity of the case, and that the tumour contained fluid; but whether it was an abscess or a softened cancerous tumour, he could not say, although from the history of the case he inclined to the former opinion. In this uncertainty, he recommended that we should wait the further development of the case, and in the interim give some simple tonic. This plan was persevered in for some time, and the case remained in much the same state until the 26th February 1853, when I was hastily summoned to her. I found her in a state of extreme collapse. She revived, however, under the free use of stimulants; and when I saw her next morning, she was almost as well as usual. About eight o'clock that evening, however, I was again hastily summoned to her, as her friends thought she was dying. I went immediately; but before I arrived, she had expired.

EXAMINATION OF THE BODY fifteen hours after death. The body was well formed, but slightly emaciated, and bore the appearance of a person who had died of hæmorrhage. There was a tumour in the left iliac region; but it appeared less prominent than during life. On opening the abdomen, the bladder was found to contain about twelve ounces of urine, and was firmly adherent to a large tumour posteriorly. The tumour, with the bladder and uterus, were removed. The uterus was of normal size. There was a large cyst which originated in the left ovary, occupying the left iliac region, and firmly adherent to the bladder. This tumour contained about a pint of grumous fluid; and behind it, at its base, were several smaller cysts containing encephaloid matter in different degrees of softening. There was no other trace of the left ovary remaining.

The right ovary was not so entirely disorganized; but there were two cysts connected with it, which contained encephaloid matter, but no fluid. There was scarcely a trace of peritoneal inflammation, nor was there any extravasation of fluid in the peritoneal cavity. As far as we could ascertain, there was no disease of any other organ.

The marked absence of pain in this case inclined us to hope that it was not malignant, and favoured the opinion that it was deep seated abscess. The sudden termination of the case was quite unexpected; nor did the *post mortem* examination clear up the difficulty; and it still remains a question what caused the sudden termination of life.

Melkham, Wiltshire, March 26th, 1853.

PERISCOPIC REVIEW.

SURGERY.

MR. SYME ON THE IMPROVEMENTS INTRODUCED INTO THE PRACTICE OF SURGERY IN GREAT BRITAIN WITHIN THE LAST THIRTY YEARS.

We reprint, with slight verbal curtailments, from the *Monthly Journal of Medical Science* for the present month, the important paper by Professor SYME, which is referred to in the foot note to Professor Miller's original article, at page 342.

The great improvements which in recent times have been so profusely contributed to the well-being of society by other departments of practical science, frequently suggest the question, Has the practice of surgery advanced in a proportionate degree? The older members of our profession, who have not quite kept pace with the march of progress, are apt to express doubts as to any real advantage having been gained of late; and our younger brethren, who are occupied more with learning present opinions than in tracing their origin, although inclined to believe that things are better than they used to be, feel rather at a loss, when called upon to explain the grounds of their persuasion. In these circumstances, I have thought that it might not be improper, from my own observation and recollection, to mention some of the improvements which have been introduced into the practice of surgery within the last thirty years.

In attempting to execute this task, I do not propose to record those particular achievements of operative surgery which merely reflect credit upon the skill and intrepidity of the gentlemen who performed them, or those new modes of treatment which are either decidedly objectionable or of questionable expediency. The excision of ovarian tumours; the aperture of the larger intestine to afford relief from obstructions of the bowels; the opening of the abdominal cavity in search of internal strangulations; the excision of the knee-joint instead of amputation; the remedy of ankylosis by forcible rupture of the adhesions between the articulating surfaces, and other less promising proposals, have all had their respective advocates; and it is not improbable that some of them at least may ultimately be established in practice. But, in the mean time, I think it is better that our attention, upon such an occasion as the present, should be confined to points of advantage so well ascertained as to leave no room for doubt in any reasonable and unprejudiced mind.

Thirty years ago, a dresser commenced the discharge of his daily duty in the hospital, by spreading a quantity of calamine cerate upon pieces of lint or linen, and cutting some sheets of adhesive plaster into narrow strips. He then proceeded to dress all the suppurating sores, by applying to each a pledget of ointment, next a cushion of carded tow, and finally a long bandage to keep all secure for twenty-four hours. At present, the use of greasy applications and elaborate bandaging is almost entirely abandoned in such cases; the water dressing, or wet lint covered with oiled silk, being substituted with great advantage, in regard not only to convenience, but also to promotion of the healing process.

The strips of adhesive plaster were devoted chiefly to the treatment of indolent or callous ulcers of the legs, according to the method of Dr. Baynton. This was a troublesome and expensive process. But it is now known that the hard swelling of the limb, which gives these ulcers their peculiar character, may be quickly removed by a large blister, so as to allow speedy healing and sound cicatrization. Varicose ulcers of the legs also used to be treated by strapping with adhesive plaster, but are now known to heal readily under the simple application of the black wash.

Another class of ulcers was held to require very severe means of treatment. This was the syphilitic, or more correctly, the mercurial sore, of a sinuous or burrowing character, which is so common wherever the delusion of mercury prevails, in all parts of the body, but especially the inner side of the legs and thighs. Its remedy was believed to be impracticable, except through the agency of caustic potass, a stick of which was pushed into all the winding sinuosities of the sore, and rubbed over the discoloured skin surrounding its orifices, so as to destroy the vitality of the unhealthy textures; with what pain to the patient may be easily imagined, and not readily forgotten by any one who has heard the walls of an hospital resounding with the shrieks of agony so excited. Now-a-days, a gentle administration of

the hydriodate of potass, to the extent of two grains, twice or thrice a-day, and a blister applied over the sore, afford relief not only without suffering worthy of mention, but much more quickly than in the other way. The same constitutional and local treatment is now found sufficient for the disease of the shin-bone, then confounded with the incurable condition of caries, and supposed to require removal or destruction of the part affected, by rasping, scraping, and the red-hot iron. Chauffers bristling with cauteries are no longer brought into the operating theatre for this purpose; and the only local treatment deemed requisite, is the application of one or two blisters, followed by water dressing.

In the treatment of simple incised wounds, or those desired to heal by the first intention, formerly, immediately after their infliction, the edges were closely approximated, and retained in contact by strips of adhesive plaster, and covered with pledgets of lint, cushions of tow, and tight bandages. As a necessary consequence, blood accumulated in the cavity sufficiently to cause separation of the surfaces, so that an abscess resulted, instead of union. Now, the greatest care is taken to allow the blood free vent so long as it is disposed to escape, all impermeable covering being withheld, while pressure is diligently applied to maintain the raw surfaces in apposition, so as to be within reach of the adhesive effusion by which their union is effected. Instead of suppuration being the almost invariable rule, and cicatrization a very rare exception, the results are now reversed; and the primary healing of wounds is looked for, if not with certainty, at least with confident expectation.

Not many years ago, one of the most painfully discouraging subjects of surgical study or practice was *gangrena senilis*. The insidious commencement of its attack; the agonising distress which attends its progress; the inefficiency of measures employed for its remedy, and the inevitably fatal result to which it led, rendered this disease indeed one of the *opprobria* of surgery. According to the ideas then entertained, nothing could be done, except keeping up the patient's strength, by an ample allowance of wine and brandy, dulling his sensibility with opium, and preparing his friends for the issue. But now, the morbid action being attributed to excessive irritability, dependent upon weakness proceeding from an imperfect supply of blood, instead of attempting to supply the deficient vigour by stimulants that can do no good, and must hurry on the disease, the treatment is directed with a view to lessening the tendency to over-action by the use of soothing means. The patient is confined to bed, debarred from animal food in every form, with the exception of milk, which, with water, constitutes his only drink, supplied with doses of morphia in proportion to his pain and restlessness, and has the part affected covered with a linseed poultice. Under this system the distressing symptoms gradually disappear, the slough ceases to extend, and after its separation the sore cicatrizes soundly, no difficulty or bad effects being subsequently experienced in returning to the ordinary habits of diet and exercise. The student, therefore, no longer turns over this page of his principles with a blush for the imperfection of surgery; and the practitioner, instead of being called upon to undertake a hopeless task, has frequently the satisfaction of conducting his patient safely through what might formerly have well been called the valley of the shadow of death.

A great revolution has taken place in regard to amputation. Formerly, upon all occasions, whether for the removal of a finger or one of the larger limbs, this operation was done by circular incision; but now it is no less generally accomplished by the formation of flaps. The advantages urged in favour of the latter method by those who established it were the facility, rapidity, and consequently smaller amount of pain, attending its execution, together with the superior covering to the bones, afforded by the resulting stump. Of these considerations, the former has lost its value through the introduction of chloroform; but the latter, which was always the more important of the two, still maintains its ground; and, with the exception of the lower part of a muscular thigh, and the upper part of the leg, where the circular method appears preferable, leaves no room for hesitation between the old and present modes.

The ankle-joints and bones of the tarsus are so liable to caries, which pre-emptorily requires removal of the affected part, that amputation of the leg was not many years ago one of the most common operations in hospital practice; and as the patients could only afford the expense of the simplest form of wooden pin, the limb was taken off immediately below the knee. But it is now well ascertained that, when the disease is so far advanced as to extend above the articulating extremities of the tibia and fibula, the patient may be relieved by detaching the

of the foot, while the thick integuments of the heel are preserved to form a cushion for supporting the weight of the body. And upon the stump thus formed, the patient may stand and walk with comfort and security, hardly less than when the limb remained entire. Moreover, the operation, instead of frequently proving fatal, like amputation of the leg, is most entirely free from danger.

Next to the ankle-joint, the elbow is the articulation most subject to incurable disease of the osseous tissue, and hence used frequently to entail upon surgeons the painful duty of performing amputation of the arm, while the hand was perfectly sound. The inferior extremity being chiefly employed in supporting the body, may be replaced with an artificial substitute, much more effectually than the arm; and indeed, so far as appearance and utility are concerned, with one preferable to the natural limb when it is much shortened, distorted, or weakened. But the hand, in its most imperfect condition, far surpasses in usefulness the most ingenious contrivance of art; and therefore preservation of the arm, even in the most crippled state, would be a great object. It is now established on the most ample experience, not only that an arm suffering from disease of the elbow-joint may be saved from amputation by cutting out the diseased bones, but that the limb thus preserved may retain its mobility and power so little altered or impaired, as to be hardly distinguishable from one in its natural state. Excision of the elbow-joint, therefore, instead of being regarded as a doubtful experiment, is now the established rule of practice. Indeed the operation is deemed so safe and so satisfactory, that even in cases where there is no existing disease, but merely stiffness of the joint in a straight or some other inconvenient position, it is undertaken, to restore mobility and usefulness to the arm.

The morbid condition which requires excision of the articulating extremities of the bones occurs in adults most frequently from ulceration of the cartilages; and to prevent any cavil on the part of those gentlemen who view all questions of pathology through the microscope, and never seem so happy as in endeavouring to unsettle the ideas of practical men by altering the nomenclature of things familiar to them, I beg to explain that by this term I understand merely a particular form of disease, characterized by peculiar symptoms leading to certain changes of texture, and remediable by certain means of treatment. Leeches, blisters, soothing means, and all the ordinary forms of counterirritation have been found productive of little more than palliation; but the actual cautery, when employed before suppuration has taken place, may be relied upon as a nearly certain and effectual remedy. The ankle, knee, wrist, and elbow joints are most liable to the disease, especially the one last-mentioned; and here the beneficial effect of surgical interference may often be witnessed in circumstances of the most impressive character. Yet thirty years ago, the actual cautery, so far as I know, had never been used in this country for the purpose of counterirritation; and even now I suspect that it is chiefly confined to practitioners who have derived their education from Edinburgh.

In the more frequent forms of articular disease which depend upon scrofulous degeneration of the textures, a no less conspicuous improvement has been introduced, not through the employment, but from the disuse, of active measures. It is now admitted that in such cases depletion and counterirritation are not only productive of no benefit but actually injurious, from the weakening effect which they produce on patients whose weak state of system is the source of derangement, and should be the great object of reparation, all that the affected joint requires being protection from motion or other causes of disturbance.

In the treatment of aneurism, especially of the femoral and popliteal arteries, a great addition has been made to the resources of surgery in the employment of pressure, not only with regard to the principles of its application, but also to the means by which this is accomplished. Indeed, recent times have afforded no greater boon to the members of our profession than they have done here to those who aspire only to mediocrity. I think it cannot be doubted that the ligature, when properly applied, is the simplest, safest, and most effectual remedy. But pressure is certainly preferable to an imperfectly performed operation; and as many of our brethren can accomplish the former, who are scarcely equal to the latter, it is plain that the treatment of this disease may now be practised with safety much more generally than it was wont to be. In retention of urine depending upon stricture, it may not be possible for all the members of the medical profession to introduce a catheter; but there are few who would experience difficulty in thrusting a trocar from the rectum into the bladder, which, although attended with no small danger, is certainly preferable to perse-

vering in attempts productive of no better results than making false passages, or leaving the patient to his fate. In the same way, if the question were to lie between exposing the femoral artery by scratching down to it with blunt instruments, such as copper or silver knives, and employing pressure, there should be no hesitation in preferring the latter method for the remedy of aneurisms admitting of its application.

The loose cartilaginous bodies which are occasionally met with in the joints, and especially that of the knee, were formerly regarded as most unpleasant subjects of practice, from the urgency of the symptoms, and the danger attending the employment of incision and extraction. In a large proportion of cases—perhaps a third, or even half—inflammation of the joints resulted from this operation, and resisting all measures of counteraction, proceeded to the destruction of the limb or life. It was hoped that a subcutaneous opening of the synovial membrane, so as to allow displacement of the moveable body, might accomplish the object more safely; but experience has taught us that, although in some cases practicable, it is generally impossible thus to effect removal, without causing such disturbance of the textures as to incur the risk of bad consequences. It is satisfactory to know that permanent relief may in most cases, if not always, be afforded, by bringing the cartilage into a part of the joint where it can be retained by external pressure, and where the coverings are thin; then making a free subcutaneous incision through the synovial membrane and the cartilage, and finally applying a small blister over the part. By this process the body becomes fixed, so as no longer to cause annoyance; and soon suffers absorption, partial or complete.

The bursa which accompanies the flexor tendons of the fingers from the wrist into the palm of the hand, is liable to morbid thickening and distension by fluid, together with solid bodies resulting from effusion into the cavity. As this condition renders the fingers nearly useless, its remedy is an object of no small consequence, but was formerly deemed almost impracticable, from the means employed proving ineffectual and dangerous. It is now ascertained that the disease may be cured easily and certainly by making an incision, about an inch or little more in length, through the integuments and subjacent textures, including the annular ligament of the wrist, on the integrity of which the peculiar obstinacy of the case appears to depend.

The great toe is liable to two morbid states which are productive of extreme inconvenience, and at no very distant date were reputed irremediable except by amputation. In one of these, the corner of the nail causes irritation and ulceration of the skin, so as to render walking painful, and wearing a shoe almost impossible. A great variety of means were formerly employed, with very little advantage, for the palliation of this complaint, but have been completely replaced by the expedient of removing a portion of the nail, by dividing it longitudinally from the free margin quite up to and through the soft texture from which it grows. This procedure not only affords immediate relief, but, when properly executed, effectually protects the patient from further uneasiness.

The other ailment is an exostosis of the distal phalanx, which projects the nail, and renders any pressure on it intolerable. The contents of museums will show that amputation was formerly practised for the remedy of this condition; but it has been long ascertained that simply removing the growth is sufficient.

The treatment of deformities proceeding from a contracted state of the muscles, more particularly wry-neck and the different forms of club-foot, has been rendered easily practicable, instead of being nearly impossible, by the employment of subcutaneous incision for dividing the tendons. Two-and-twenty years only have elapsed since the first operation of this kind in Great Britain was performed on the sternal attachment of the sterno-mastoid, and now tenotomy is almost the daily duty of a surgical practitioner—with what advantage can hardly be imagined by any one who cannot recollect the tedious and unsatisfactory attempts, that were made in former times to accomplish the object by the unaided effect of mechanical support. It must be admitted, however, that the introduction of this system has led to a most serious evil in developing a new set of specialists, under the title of Orthopædists, who are doing an incalculable amount of mischief to the public and the profession by reviving and carrying to an unprecedented extent the use of apparatus, in cases where it can never be otherwise than either hurtful or productive of no benefit. It is surprising that the apathy of medical men should tolerate the practices of these persons, especially in regard to lateral curvature of the spine; and I can account for their silent endurance only by attributing it to the slavish fear of running counter to popular prejudice, and in-

curring the enmity of those who thrive on the delusions which spring from this source.

The bad effect of withdrawing a particular operation, or the treatment of a particular disease, from the general practice of surgery, is well illustrated by what has happened in regard to the cure of squinting, by division of the muscles which cause this deformity. The public was greatly delighted with the prospect of relief from an unseemly and inconvenient condition, which had baffled all previous attempts, and readily submitted their eyes to any who undertook the reparation of their obliquity on the new system. From the lowest level and thickest obscurity, through the united influence of impudence and credulity, a host of squint-cutters started into notice; and although they might never before have used the knife or scissors on a living human body, freely practised on the patients who crowded round them. But the process required being a surgical operation of great nicety, and entirely useless unless complete, it is not surprising that in such hands failure was more frequent than success; and the former result, instead of being attributed to its true source, was accounted for by alleging that the relief was not always permanent, and that relapse could not be prevented. The operation, therefore, got a bad name; and although deserving the greatest confidence, is even now labouring under the obloquy incurred by its self-constituted and unworthy professors.

Both the upper and lower jaws are liable to morbid growths, of the same nature as those which occur in other parts of the osseous system, and have long been remedied by amputation. Sometimes they are soft and cerebriform, at others of a firm fibrous or fibro-cartilaginous consistence. In both cases removal was formerly attempted by laying open the cheek, exposing the tumour, and digging it out so far as possible by scissors or chisels, and finally applying caustics or cauteries to destroy any portion that might remain. But such proceedings, however bloody, severe, protracted, and dangerous, hardly, if ever, accomplished the object in view; and so far from even prolonging the patient's existence, generally shortened it, under circumstances peculiarly revolting and distressing. In one of the cases which I recollect seeing thus treated, the actual cautery was applied forty times, and the daily dressing, with its stench and maggots, was a scene not soon to be forgotten. About thirty years ago, a better plan of affording complete extirpation was introduced, upon the principle of ascertaining the limits of the growth, and then dividing the bone beyond the disease, where it was known to be sound. This principle was applied first to the lower, and then to the upper jaw, with the most distinguished success and advantage; tumours of the most formidable character being removed from both situations easily, safely, with little deformity, and with permanent relief. Like other good measures, this operation has been abused, by employment in cases either not requiring or not admitting of its beneficial performance, as when the tumour depended upon a glandular enlargement adherent to the bone, or upon growths proceeding from the bones of the skull, and simulating enlargements confined to the maxillary region. But the untoward results of such unwarrantable doings should not be allowed to lessen the credit of what ought to be regarded as one of the greatest improvements of modern surgery.

Both the superior and inferior maxillary bones are liable to the formation of serous cysts, which originate within the osseous substances, and so expand it as to resemble solid growths through the firmness of their walls, which, however, are always, in part of their extent, so yielding to pressure, that a careful examination is sufficient for detecting the nature of the case. These cysts were formerly thought to require very severe treatment, and at least laying open throughout the whole of their extent, together with the application of caustic, or the actual cautery, to destroy their secreting action. But now it is well known that such strong measures are quite unnecessary, the only essential requisite for contraction and obliteration of the cavity being an ample aperture, so situated as to allow free vent to its contents, and that for this purpose it is sufficient to remove an elliptical portion of the parietes, to prevent the speedy closure which would result from a simple puncture or incision.

Suppuration of the maxillary antrum also is now treated much more satisfactorily than it was wont to be: since it has been ascertained, that although a small opening may suffice for palliation, a free one is essential for complete relief. The old practice, therefore, of drilling a hole through the socket of a tooth, and throwing up injections by this narrow channel, in the thick alveolar ridge, to wash out the cavity, has been superseded by the much easier, and far more effectual plan of lifting up

the lip, and cutting parallel with the gum, above the bicuspid teeth, so as to make a free opening into the antrum, where its anterior wall is thinnest. If this be properly done, no further treatment is required; and the lesson thus afforded is useful in regard to the healing of all sinuses, whether of the hard or soft parts of the body, by showing the importance of effectual drainage, which will always be found preferable to injections and other expedients of an unsound pathology.

The tumours of the nasal cavity, which are comprehended under the title of polypus, were formerly supposed to be of only two kinds—the simple or mucous, and the malignant, so that the peculiar sort of growth, characterised by its firm texture and hæmorrhagic disposition, which is now known by the name of fibrous, not being distinguished from the others of a bleeding nature, was along with them deemed irremediable. But we now know that of all polypous tumours, this is the one which most requires and admits of relief, whether we regard the gravity of its symptoms, or the permanence of recovery after removal. Indeed there are few cases of surgery in which the efficiency of interference is more distinctly shown than when a patient, oppressed by obstructed breathing, and exhausted by frequent hæmorrhage, is instantly transferred, by a proper application of the forceps, to comfort and security.

In extracting the ordinary kind of polypus, there has been a great improvement in the instrument employed, and the mode of procedure. Formerly the forceps were large, with windows or apertures in their blades, to increase the security of grasp, and the operator aimed at seizing the body of the tumour. But now these growths being known to originate from a small portion of the cavity, however large they may be, and whether they project forwards, or hang down into the pharynx, forceps of the smallest possible size consistent with the requisite degree of strength are gently insinuated towards the root, which they separate by a combined movement of torsion and evulsion. The object in view is thus accomplished not only with infinitely less suffering, but far more effectually, than according to the old system; and the patient, instead of being tormented by a succession of sittings, as the abortive attempts were named, is at once freed from trouble. It is hardly necessary to add, that the old plan of noosing a polypus, by slipping over it loops of ligature or wire introduced into the nose, or through this cavity into the pharynx, has been entirely rejected from the rational practice of modern surgery, though it may still decorate the pages of those compilations for the use of students, which perhaps assist them to pass their examinations, but can never convey sound principles of practice.

In restoration of the nose, and other important parts of the face, destroyed by disease or injury, two methods were formerly taught, although only one of them was, so far as I know, ever practised in this country. These were the Taliacotian and Indian operations, of which the former was effected by borrowing the requisite portion of integument from some other part of the body; while the latter accomplished the object by turning round a flap from the neighbouring skin so as to supply the deficiency. The procedure last mentioned is the one that was formerly always employed, but has now been superseded by another, which, wherever practicable, seems greatly preferable. This, which may be called the plan of lateral displacement, supplies the defect by separating flaps of skin from their sub-jacent connections, and transferring them to the side where they are required, without any twisting of the connecting isthmus. Any one who has practised the latter method, or witnessed the facility with which it is accomplished, will find difficulty in conceiving how the other could ever have been employed.

Enlargement of the tonsils occurs very frequently at an early period of life, impeding respiration, especially during sleep, rendering the voice husky, causing a disposition to sore throat, and occasionally producing a degree of deafness. Thirty years ago, the practice of surgery in Great Britain did not afford any effectual remedy for this disease. The French method by excision had not been adopted; and what was called the English operation by ligature, though taught in the schools, was never attempted, at all events, more than once by the same practitioner. Removal by the knife was introduced in Edinburgh, and, through the influence of gentlemen educated here, is now widely extended, notwithstanding a certain degree of discredit which it has acquired, from the proceedings of those specialists who profess to cure cases of deafness usually reputed incurable; and, among other means for this purpose, are alleged to cut tonsils in no wise redundant, or in any respect warranting interference. The operation, when properly performed, in circumstances really requiring it, affords, with perfect safety, such an

amount of speedy and permanent relief, as justly to merit the title of a substantial improvement in the practice of surgery.

Opening of the chest for evacuation of fluids accumulated in its cavity was formerly accomplished by an incision in one of the intercostal spaces most convenient for the purpose, but with results so unsatisfactory as to be regarded a very nearly, if not entirely, hopeless undertaking. In the first instance, there was considerable risk of fatal inflammation; and at a later period, if he escaped this danger, the patient was almost sure to be carried off by the exhaustion of continued discharge. Instead of this unpromising procedure, a great improvement has been introduced, by substituting for the knife a slender trocar, which is thrust directly through the parietes of the chest without any preliminary incision. The wound thus inflicted does no more harm than the puncture of a needle, and may be repeated without any fear of bad consequences, however often it may be requisite for the patient's relief. Thus upwards of 600 ounces of purulent fluid have been withdrawn, with the effect of complete recovery, while in others one or two tapings have been sufficient for the purpose.

The operation for hernia is now frequently performed without opening the sac; and although this modification is not applicable to all cases, there can be no less doubt that, if judiciously employed, it tends greatly to lessen the difficulty and danger. There seems indeed to be room for fear, that the division of the constricting textures has thus been rendered so simple as to deprive the groin of that careful attention, which in times past was devoted to it by students of surgical anatomy. But as nothing can steady the hand of an operator so effectually as knowledge of the structure concerned in his proceedings, I venture to hope that the rising generation of surgeons will not neglect the inguinal fasciæ, which it cost their fathers so much trouble to unravel.

In the treatment of hydrocele, a great improvement has been introduced by the substitution of iodine for the port wine formerly employed, since the process of injection is thus rendered much more safe and certain. Various mixtures and combinations are still employed for the purpose; but it appears to be fully established, that from one or two drachms of the tincture injected into, or allowed to remain in, the *tunica vaginalis*, afford the easiest, least painful, and most effectual means of curing the disease. The various measures, therefore, of which the contending claims for confidence were formerly the constant subject of discussion, no longer embarrass the course of practice; and candidates for medical honours have ceased to select the treatment of hydrocele as the theme of their inaugural dissertations.

Fungus of the testicle, although removed from the category of malignant diseases, to which it was formerly referred, continued until lately to be deemed remediable only through removal by knife or caustic. It is now well established, that the protrusion admits of recovery by absorption of its interstitial effusion; and that for this purpose an easy and effectual method is to detach the scrotal integuments from their subjacent connexions sufficiently for allowing them to unite over the tumour, and thus subject it to the influence of compression. In this way the object is speedily attained, and the portion of gland preserved may perhaps be still able for the performance of its function.

The extraction of urinary concretions from the bladder has been much improved, in the first place, by the introduction of lithotripsy or stone-crushing; and, secondly, by the establishment of sound principles for the performance of lithotomy. When the stone is small, it may be easily and safely crushed; but if it is of a size so large as to require frequent repetition of the process for the removal of fragments, there is great risk of disagreeable consequences, both immediate and remote; and the cutting operation, therefore, not being superseded, should be rendered as perfect as possible. Formerly a mysterious uncertainty brooded over this subject; and surgeons who successfully achieved all the other difficulties of practice, failed signally in cutting for the stone; while others, notoriously deficient in the ordinary qualities, not only of head but also of hands, acquired the reputation of skilful lithotomists. When the latter were asked to explain their mode of procedure, they gave the most conflicting accounts of it, some maintaining that "the less that is cut, the greater the patient's safety", and protesting against more than notching the apex of the prostate, while others insisted upon the necessity of obtaining ample space by free incision of the vesical coats. But when the operation was conducted upon the first of these principles, it was almost certain to prove fatal from suppurative inflammation at the neck of the bladder; and when the second was taken for a guide, extravasa-

tion of urine no less regularly followed. Operators who supported these different doctrines freely charged each other, no matter how successful, with not knowing the actual extent of their incisions, so that doubt and discomfort were unavoidable by all except those fortunate individuals who happened to acquire the knack of overcoming the difficulty. But now the truth has been fully ascertained, and the reason of failure, as well as of success, is correctly referred to its proper causes. The great source of difficulty and danger is found to be a particular texture, which lines the interior of the prostate at its base to the extent of about half an inch in thickness. This sort of ring admits of being stretched to a certain degree, but then resists further expansion with great force; and if torn by violence, is sure to excite a fatal inflammation of the neighbouring parts,—while, if it is divided by incision, no bad consequence results, and the other tissues at the neck of the bladder readily yield to any expanding force, so as to permit the extraction of even large stones easily and safely. The surgeon, therefore, after making an adequate opening through the subjacent fasciæ and muscles of the perineum, has merely to make sure of cutting this important part, which may be done most safely by a knife, guided on the finger, and then with the latter dilate the other textures sufficiently for his purpose. This procedure was formerly hardly practicable in adults, except by an operator possessing a long finger; but may now be always easily accomplished through the aid of chloroform, which prevents the straining and contraction of the *levator ani*, which in a conscious patient withdraws the neck of the bladder deeper into the pelvis.

In the treatment of stricture, it has been found that all contractions of the urethra which yield to dilatation may be remedied most easily and safely by the simple bougie, and that those which resist the proper application of this means admit of no effectual relief, except by external incision upon a grooved director, conveyed through the narrow part of the canal. These points being duly established, will, it is hoped, prevent professional attention from suffering distraction by the conflicting claims of less effective measures, and, concentrating it upon what appear to be the simplest and safest, throw completely into the shade those objectionable precedents that would never have been tolerated except as forlorn hopes, in circumstances deemed otherwise entirely desperate. It may be now confidently said, that if any man endures continued distress, or loses his life, from stricture, the blame is no longer imputable to the defective condition of surgery; and if the Marquis of Argenteuil had still to make his will, I hardly think he would found a prize of £500 to be conferred at stated periods for practical improvements in the treatment of this disease.

Diseases of the rectum, from being much in the hands of specialists and irregular practitioners, have been slow in their progress towards improvement. Indeed, until a comparatively recent period, they were regarded as a sort of incomprehensible mysteries, unworthy of professional attention. Thirty years ago, fistula in ano was thought to require division of the septum between it and the bowel, to the whole of its extent. An internal opening, if present, was supposed to be at the summit of the cavity; but, whether present or absent, was considered of secondary consequence. The surgeon, therefore, arming his finger with a horn gorget, thrust it up the rectum, and then inserted into the fistulous canal a sharp bistoury, having its point guarded by a pea or bit of wax, until it reached the extremity, when pressure was made upon the gorget, and both instruments were drawn out together. Profuse hæmorrhage frequently followed this deep incision, and great care was requisite, for three weeks or months, to prevent adhesion of the edges, by the daily introduction of dressing between them. This operation often required to be repeated, and not seldom proved entirely abortive. Now we know that the fistula always takes its origin from an abscess in close connexion with the mucous coat of the intestine, which, in the first instance, with few exceptions, opens outwardly, and after a time establishes a connexion with the cavity of the bowel by a small aperture, seated very regularly at the distance of an inch, or inch and a quarter, from the orifice of the anus. All that is necessary, is division of the septum between the internal and external openings; and the operation is not only very easy, perfectly free from risk of hæmorrhage, and so superficial as not to require any dressing, but, what is of more consequence, always proves successful.

Internal hæmorrhoids, which occur so frequently, especially in the upper ranks of society, and occasion so much distress by causing protrusion, bleeding, or pain, or all of these effects together, were formerly subjected to excision, ligatures, caustic, and the actual cautery, with various and often unsatisfactory consequences. It now has been long established, that the liga-

ture, when properly applied, affords relief with most ease to the patient, with most permanent advantage, and with greatest security from danger. It is true that no operations can be considered absolutely free from risk; but I am not acquainted with any one of the minor kind which is so seldom followed by a bad result, as the ligature of internal hæmorrhoids.

Fissure of the anus is the source of such excessive pain and annoyance, that the severe means formerly held to be essential for its remedy were occasionally practised, although both patient and practitioner generally shrunk from the performance of so serious an operation for so trivial an ailment. Instead of a complete division of the sphincter, and a confinement of months to bed, it is now well ascertained that a small incision, slightly exceeding the length and depth of the little ulcerated fissure, is sufficient for its remedy, without any after treatment, or restriction from exercise, beyond a day or two of quiet.

Spasmodic stricture of the anus, which was formerly either regarded as incurable, or tortured by ineffectual attempts to afford relief by dilatation, is now remedied at once by division of the external sphincter, with an amount of comfort, and an immunity from suffering, that can hardly be conceived by any one who has not witnessed such cases.

The only organic stricture of the rectum which admits of remedy is now known to be situated within little more than two inches from the anus; and the preposterous proceedings to which credulous patients were formerly subjected by the rapacious empirics who pretended to cure contractions far up the bowel, or even in the sigmoid flexure and ascending colon, are no longer heard of; and if an man were now to wield a rectum bougie, two feet in length, he would do so at the risk of being deemed worthy of accommodation in Newgate or Bedlam. The amount of human misery which has been, or may be, saved by the alterations thus introduced into the treatment of diseases of the rectum, it would not be easy to calculate.

Enough has, I trust, been said to show that surgery during the last thirty years has not stood still, but, on the contrary, introduced into practice so many useful improvements, that the practitioners of this time have no reason to be ashamed of it, or to fear its comparison with any other period of similar extent in medical history.

POLYPI OF THE LARYNX.

The *Gazette des Hôpitaux* for January 20th quotes from the *Gazette Médicale de Strasbourg* some remarks by Dr. TOURDES, on polypus of the larynx.

The history of the disease is almost entirely contained in the work of Professor Ehrmann. He relates thirty-one cases, of which only one recovered, after the timely employment of tracheotomy. Dr. Tourdes also gives the details of a case which proved fatal.

CASE. A. St. J., aged 7, the child of poor parents, was admitted into the Orphan Asylum at Strasbourg in September 1852. The child was of feeble constitution, and had goitre, with some signs of cretinism. He had been for some time subject to dangerous attacks of suffocation. Soon after his admission, he was seized with violent attacks of cough, threatening asphyxia; and was taken into the children's sick ward, on November 16th.

When admitted into hospital, he was very anxious; at times, asphyxia seemed imminent. During the attacks, the respiration was noisy, whistling, convulsive, and attended with a hoarse cough. Expiration seemed much more painful than inspiration. There was no expectoration. In the intervals, the dyspnoea continued; the voice was hoarse and changed, but never entirely lost; the cough was frequent. There was great diminution of the respiratory murmur in both lungs, but no rhonchus: the breath-sound was whistling in the trachea and larynx. The fauces and pharynx presented no trace of false membrane, but merely a slight redness. No pain was produced by pressure on the larynx: there was no enlargement of the cervical lymphatic glands. The skin was cold, and the circulation accelerated.

The diagnosis was difficult. There was no evidence of a foreign body in the larynx; nor were there sufficient grounds for attributing the symptoms to cough, abscess in or near the larynx, or acute laryngitis. Hence it was concluded that the disease was polypus of the larynx; but this diagnosis was rendered uncertain by the absence of any information as to the previous condition of the patient.

Vomiting was excited by tartar emetic; burnt alum was blown into the larynx, and solution of sulphate of copper was applied to the fauces: mercurial frictions were also employed. Tracheotomy was at first discussed, but was negatived on the

ground that all the cases of a similar nature, in which the operation had been performed in the institution, had proved fatal.

There was no alleviation of the symptoms; double pleurisy set in, and the patient died on November 24th, during an attack of dyspnoea.

Post Mortem Examination. A reddish, soft, nodulated tumour, of the size and shape of a flattened strawberry, occupied the left ventricle of the larynx, and extended over the arytenoid cartilages, as far as the right ventricle, which was unaffected. The posterior and left lateral part of the glottis was closed by this polypus, which occupied about two-thirds of the opening. It was adherent to the larynx by a broad base; in this respect alone differing from the vegetations described by M. Ehrmann. The lobes of the thyroid body were largely developed, and joined in front of the trachea. The pleurae were lined with a thick layer of soft false membranes. The tissue of the lungs was only congested; the bronchi contained much frothy mucus; the mucous membrane was healthy.

REMARKS. The want of information as to the previous history of the patient was the principal impediment to arriving at a correct diagnosis; and if this had been possible, tracheotomy might have been performed with some chance of success. The recorded cases of polypus of the larynx show that the progress of the disease, and the gradual development of the symptoms, have always furnished decisive signs. There is no pathognomonic sign, although the greater difficulty of expiration, the expectoration of portions of the polypus, or even its projection above the glottis, have been mentioned as such: these may be all absent.

After tracheotomy had been performed, the tumour would have to be removed. In the only successful case recorded by M. Ehrmann, he cut open the larynx, and excised the polypus, two days after the performance of tracheotomy. In M. Tourdes' patient, the tumour adhered by a broad base; which would have increased the difficulty of cure.

PRACTICE OF MEDICINE AND PATHOLOGY.

VICARIOUS EXCRETION OF URINARY AND BILIARY PRINCIPLES BY THE LUNGS: RESEARCHES OF DR. C. BLACK.

In a series of papers at present being published in the *Monthly Journal of Medical Science*, Dr. C. BLACK describes, in the number for the present month, an affection which he terms pulmonary cellulitis—or inflammation confined to the epithelium of the pulmonary cells, extremely prevalent among children, and often regarded as pneumonia, and not rare in adults. In it, and in "epithelial bronchitis", the products of inflammation appear on the free surface of the membrane; while in pneumonia, intercellular exudation, corresponding with the submucous exudation of severe bronchitis, occurs. Pulmonary cellulitis is more common in the lower than in the upper half of the lungs; in the posterior than in the anterior portions; in children than in adults: it may occur suddenly, or supervene on either the epithelial or the severe form of bronchitis.

In the course of his paper, Dr. Black makes some statements which are of much interest in connexion with the communication of Dr. Joseph Bullar, published at p. 347 of this number. He says:—"As to the chemical composition of the sputa in cellulitis, after the full establishment of expectoration, the mean of eighteen analyses, uninfluenced by hereditary taint or constitutional peculiarity, gave

	In 100 parts.
Water	94.80
Organic matter	3.68
Chlorides of sodium and potassium,	1.47
Alkaline sulphates and phosphates	
Sulphate and phosphate of lime	.05
	100.00

"When, however, a constitutional peculiarity, a peculiar diathesis, or another disease is associated with cellulitis, the exudation from the pulmonary membrane contains frequent evidence of the presence of certain products, dependent on such peculiarity of constitution or on disease. I have, consequently, found the uric acid diathesis furnish urate of ammonia to the sputa of cellulitis,—the oxalic acid diathesis distinct crystals of the oxalate of lime, together with the occasional presence of cystine,—and jaundice, cholesterine, and the colouring matter of the bile."

In illustration of each of these facts, Dr. Black gives an example.

In the first case, the patient had acute articular rheumatism, with epithelial bronchitis. On the second day, the urine deposited a thick yellowish-red sediment of urate of ammonia: the expectoration was thinly viscid and frothy, consisting of epithelial patches and mucus-corpuscles. During the night, the breathing became oppressed, with weight and burning in the lower and posterior part of the right side of the chest, cough, and partial suppression of expectoration: the physical signs indicated cellulitis. On the third day, the urine deposited urate of ammonia: the expectoration was re-established, and becoming more copious. It was seen to consist of a few epithelial patches, mucus-corpuscles containing distinct globules of urate of ammonia, free urate of ammonia, exudation masses and cells, and irregularly shaped flakes and masses of fibrin. During this and the following day, the urate increased in the urine and diminished in the sputa. On the fifth day, no trace could be discovered in the sputa. On the ninth day it reappeared in the sputa, at which time the urine was quite free from it; but on the morning of the eleventh and during the remainder of that day, a copious excretion of the urate took place from the kidneys; and on the following day there was no appearance of it in the sputa. From this time the urate was confined to the urine, in which, on the fourteenth day of the disease, a very copious sediment occurred. The cellulitis henceforth rapidly disappeared: and on the twenty-second day, convalescence from rheumatism was established.

That the globules seen in the sputa were urate of ammonia, was proved by the production from them of uric acid crystals by the addition of hydrochloric acid, and by the formation of murexide on the addition of nitric acid and ammonia.

In the second case related, a medical student, aged 20, while under treatment for oxaluria, took cold from incautious exposure, and pulmonary cellulitis supervened. On the establishment of the expectorant stage, examination of the sputa proved the occasional presence of urate of ammonia, and of oxalate of lime, particularly at the time when they were being eliminated by the kidneys in small quantity, and were hence accumulating in the blood. Crystals of the oxalate were present in the mucus-corpuscles to a limited extent, being for the most part free in the sputa; but the urate of ammonia was not infrequent in the mucus-cells. In the wood-cut accompanying this case, the form of crystal of oxalate of lime in the sputa is the octohedral: this, with the dumb-bell and ovoid forms, were found in the urine.

In the third case, pulmonary cellulitis supervened on jaundice in a woman lately confined. The sputa exhibited plates of cholesterine.

In all these instances, Dr. Black employed the usual chemical tests, which confirmed the appearances presented under the microscope.

From the foregoing cases, which are only single examples of several which have occurred to him, he draws the following deductions:

"1. That the manifestation of a particular diathesis, or the presence of a particular disease in the system, is capable of influencing the character of the sputa in inflammation of the bronchio-pulmonary membrane.

"2. That this influence is manifested by the presence, in the sputa, of the morbid products of the particular diathesis or disease with which inflammation of the bronchio-pulmonary mucous-membrane is associated.

"3. That such morbid products are eliminated by the epithelial cells of the membrane; that they, therefore, appear as accidental constituents of the mucus-cells; that they likewise escape in the exudation from the denuded surfaces of the basement membrane; and that they are never present in the exudation cells.

"4. That the bronchio-pulmonary epithelium can thus act the part of an excretory organ: but that this peculiarity of action is probably rather dependent on the particular character of the blood, than on any selective power inherent in the cells.

"5. That before such eliminative action takes place, an undue accumulation of morbid products occurs in the blood; that the action of the different organs, intended for the elimination of such morbid products, is for the time being deficient; and that on its becoming more vigorous, the sputa quickly regain their normal character."

LOCAL EFFECTS OF PUS ON THE BLOOD.

Some time ago, the Edinburgh Physiological Society appointed a committee to repeat Mr. H. LEE's experiments; and at the meeting of the 8th of January, Dr. HUGHES BENNETT read the report of the committee, which we reprint from the *Monthly Journal of Med. Science* for March 1853.

EXPERIMENT I. The saphena vein of an ass was exposed, and a tube introduced confined by a ligature. Fresh and healthy pus was then slowly injected upwards towards the heart, from a syringe holding an ounce. A slight obstruction was now perceived, and the vein above the ligature could be seen to be somewhat swollen. This swelling, on being felt, was very soft; and on pressing the vein from below upwards, the mixed blood and pus was readily pushed before the finger, when all obstruction to the passage of pus from the syringe was removed. The syringe was again filled, and another ounce of pus injected, without occasioning any further local effects. The animal was then allowed to get up, and exhibited no change in its normal condition whatever.

EXPERIMENT II. The same ass was the subject of this experiment a fortnight later, having been perfectly well in the interval. Six inches of the jugular vein in the neck were carefully dissected and exposed; and a minute aperture was then made in the upper end of the exposed vein, and the bent tube of the syringe introduced without a ligature. The coats of the vein were so transparent, that the flowing blood could be seen through them. An ounce of fresh and perfectly healthy pus was then slowly injected downwards towards the heart; and, owing to the transparency of the vein, the yellow opaque fluid was seen to join the blood, and to continue a few moments running side by side with the crimson current, until at length the vein became full of pus. On removing the syringe to obtain a fresh supply, the blood from above could be seen to join the pus, and to continue side by side with that fluid, presenting a streaked red and white appearance, without any coagulation, until all the pus was carried forwards and downwards towards the heart, and the vein was again full of blood. Another syringe-full of pus was then injected, which could once more be seen first to flow with the blood, then, as its quantity increased, to take the place of the blood, and then, on the syringe being exhausted, to receive blood from above; the two mixing together, and continuing their course without coagulating, until once more the vein contained nothing but blood. The wound was now closed, and the animal allowed to rise, which he did without apparent suffering. He presented no unusual symptoms whatever during the next four days, when he was killed, and the parts carefully dissected. The vein was pervious, presented no thickening, cording, nor abscesses, and the external wound was nearly healed.

This experiment appeared to be so decisive, and so clearly opposed to the idea that the contact or mixture of pus and blood necessarily induced coagulation in a living animal, that it was thought unnecessary to repeat it. With regard to the slight coagulability apparently occasioned in the first experiment, it was attributed partly to injecting contrary to gravity, whereby the mixed pus and blood were allowed to fall backwards and remain stationary, while the ligature prevented any flow of blood from being continued. No such phenomenon was observed in the second experiment, where no ligature was employed, and where the effect of gravity was avoided by injecting downwards. In a communication, however, received from Mr. Henry Lee, he had informed Dr. Bennett that no ligature was employed by him.

The second experiment performed by the committee was in its nature the same as the seventh and eighth experiments of Mr. Henry Lee, and yet none of the appearances observed by that gentleman resulted. There was no fulness or cording of the vein, no acceleration of respiration or constitutional symptoms; and after death, no coagulation of the blood, no obliteration of the vein, nor local inflammation. What are the circumstances which occasioned this difference, the committee are not prepared to say; but the positive fact of having introduced the pus on two separate occasions, as recorded in Experiment II, of having seen the pus mix with the blood, and the blood with the pus, through the transparent vein, without producing coagulation, is, in the opinion of the committee, sufficient to negative the general proposition, that whenever pus is mingled with blood in a living animal, coagulation of the latter fluid is the invariable result.

Dr. GAIRDNER remarked, that these experiments did not necessarily disprove the conclusions arrived at by Mr. Henry Lee, of London, from his observations; but he (Dr. G.) considered that further investigation into the mode of experiment-

ing adopted by different individuals, might tend to reconcile the apparent discrepancies in their statements as to the effect of pus on the blood.

SACCHARINE URINE IN EPILEPSY.

The urine of epileptic patients, immediately after a paroxysm, has been repeatedly found by MM. MICHÉA and ALVARO REYNOSO to contain sugar. The ordinary method of detecting it by solution of potass fails in this instance, as likewise does the saccharimeter; but the best mode is to employ fermentation and the liquor of M. Barreswil. In using this latter, certain precautions are necessary. The urine is first to be treated with acetate of lead to precipitate the organic matter, and then with carbonate of soda to throw down the salt of lead. Concentrate the urine, add the liquor of M. Barreswil, and boil. Without these indispensable precautions to get rid of the organic matter, the presence of sugar is not determined with sufficient accuracy; or reactions may even occur which would denote its presence when really absent.—*Comptes Rendus*, Janv. 31, 1853.

ANATOMY AND PHYSIOLOGY.

COLOUR PRODUCED IN SILK THROUGH THE MEDIUM OF THE FOOD OF THE SILK-WORM.

It has long been known that certain colouring matters, if administered to animals along with their food, possess the property of entering into the system and tinging the bones. In this way the bones of swine have been tinged purple by madder; and instances are on record of other animals being similarly affected. No attempt, however, was made to turn this discovery to account until lately, when M. ROULIN speculated on what might be the consequences of administering coloured articles of food to silk-worms just before spinning their cocoons. His first experiments were conducted with indigo, which he mixed in certain proportions with the mulberry leaves serving the worms for food. The result of this treatment was successful; he obtained blue cocoons. Prosecuting still further his experiments, he sought a red colouring matter, capable of being eaten by the silk-worms, without injury resulting. He had some difficulty to find such a colouring matter at first, but eventually lighted on the *Bignonia chica*. Small portions of this plant having been added to the mulberry leaves, the silk-worms consumed the mixture, and produced red silk. In this manner the experimenter, who is still prosecuting his researches, hopes to obtain silk, as secreted by the worm, of many other colours.

OVA OF FISH IMPREGNATED WITHIN FEMALE.

DR. ROBERTSON, of Dunkeld, questioning the popular idea as to the natural history of fish, which is, that the male and female meet on the redd or spawning bed for the purpose of each depositing its roe and milt in the channel—and conceiving, on the contrary, that the ova of the female were impregnated previous to their development within the body of the fish, took a number of live female trout from the spawning-bed, and having extracted the roe, deposited them in a perforated zinc box, containing some gravel. All these, upon the 14th of October last, were placed in a running stream, and on examining the box last week, several of the ova were found to be hatched, of which a specimen may be seen by any one taking an interest in the matter. The proof of this will completely do away with the trouble of obtaining the milt to apply to the roe, as is done by the French fishermen, and establishes a theory strongly advocated by Mr. T. Stoddard. From the severity of the winter, the whole of the ova are not yet hatched. We understand that the doctor is preparing a detailed account of the experiment.—*Perth Courier*.

ASSOCIATION INTELLIGENCE.

SOUTH WESTERN BRANCH.

A MEETING will be held at the Devon and Exeter Hospital, on Tuesday, the 26th instant, at 1 P.M., to receive the Report of the Committee appointed to confer with the promoters of the Medical Reform Bill, and to determine on such measures as may be deemed advisable.

As this Bill, if passed into law, may materially influence the position of practitioners in medicine generally, the gentlemen of the medical profession, residing in Devon and Cornwall, although not members of the Association, are invited to attend and to take part in the proceedings.

W. D. KINGDON, M.D., Secretary.

St. Thomas's Hospital for Lunatics, near Exeter, April 18th, 1853.

EDITOR'S LETTER BOX.

LORD LYTTLETON'S VACCINATION BILL.

LETTER FROM ROBERT CEELY, ESQ., TO THE EDITOR.

SIR,—I beg to offer you my hearty thanks for your able article in the ASSOCIATION JOURNAL of last week, on "Compulsory Vaccination", in every word of which I cordially concur.

I hope our brethren (of the ASSOCIATION in particular) will promptly respond to your just and energetic appeal before it be too late. They must be aware that it will be worse than useless to force upon the profession and the public a scheme of compulsory vaccination, infinitely more objectionable in its character, and far more injurious to the profession, than the present act, with all its vices and imperfections.

Those who are zealous for the character and credit of vaccination, and desirous of defending the profession from renewed and "barbarous" injustice, ought to lose no time in earnestly petitioning Parliament to reject, *till further inquiry*, the hasty and random attempts at legislation of well-intentioned but ill-advised philanthropists, on a subject confessedly replete with difficulties, and needing the most careful and enlightened consideration of the best informed. Those who know anything of the matter must admit that the public has far greater need of the means for extending *efficient* vaccination, than a measure which seeks merely to establish the principle of compulsion. The propagation of small-pox may and ought to be restrained by far less impolitic and objectionable means than the recognition and enforcement of that principle.

But the extension of *efficient* vaccination requires very different measures than the existing or projected law provides. Any amount of success professedly resulting from the present law, is derived from the unrequited zeal and the personal and pecuniary sacrifices of those members of the profession who are already taxed beyond endurance. *Efficient* vaccination is no necessary result of that act, which has disappointed its advocate and promoters, and proved to its active agents a source of injury, oppression, and degradation.* And who will not venture to predict that the measure now in contemplation, instead of accomplishing the intentions of its advocates and promoters, is more likely to *disparage and discourage vaccination, and still further to damage and disgust the medical profession?*

I earnestly hope, sir, that our colleagues of the ASSOCIATION, individually and collectively, will promptly exert themselves to secure for vaccination and the profession that consideration to which, for the benefit of the public, both are pre-eminently entitled.

I have been anxiously engaged in endeavours to attract the attention of eminent official persons to the subject, in which I feel a deep and enduring interest; and I now place at your disposal the copy of a letter I have had the honour of addressing to Lord Viscount Palmerston, on small-pox repression and vaccination extension.

I may add, that similar letters have been addressed to the Registrar-General, Lord Lyttelton, and the Epidemiological Society.

With renewed thanks for your valuable labours, and with an earnest desire for their success, I am, etc.,

ROBERT CEELY.

Aylesbury, April 18th, 1853.

COPY OF MR. CEELY'S LETTER TO LORD PALMERSTON.

To the Right Honourable Lord Viscount Palmerston, Her Majesty's Secretary of State for the Home Department.

Aylesbury, 30th March, 1853.

MY LORD,—I venture to address your lordship on small-pox and vaccination, believing that the importance of these subjects to the community will be deemed my best apology for the in-

* "In almost every locality the working of the Act has led to dissension and altercation, either between the guardians and resident practitioners, or among the latter themselves."

"As respects the profession, therefore, the measure has proved one of injury, oppression, and degradation; while, with reference to its professed object, it must be considered a failure."

"The efforts of medical practitioners to extend vaccination among the working classes have been checked by removing the ordinary inducements and facilities for its performance; and the distrust and apathy of the poor have been increased, by connecting this invaluable protection, with the administration of the Poor Law."—*Preliminary Report of the Poor Law Committee of the Provincial Medical and Surgical Association (1850)*. Second year, page 115. Sherwood and Co.

trusion. But I have an urgent motive for doing so at this time, as the attention of Parliament is already called to the subject of *compulsory vaccination*.

The prevention of small-pox and the extension of vaccination are deserving of the serious consideration of the legislature.

It is earnestly to be hoped that the hasty, imperfect, and erroneous measures, relative to these and kindred subjects, which have emanated therefrom of late years, may soon be deliberately reconsidered, more efficient measures devised, and the administration of them delegated to appropriate and active authority.*

The annual sacrifice of human life by the retention and propagation of small-pox among us, the facility with which it can at any time be arrested by the prompt performance of vaccination, and the incalculable benefits which would flow from the universal adoption of that practice, have induced many humane and philanthropic persons, in and out of the medical profession, earnestly to call for *compulsory vaccination*.

Cordially concurring in the absolute necessity of stringent and decisive measures for the repression of small-pox, and earnestly desirous of the extension of vaccination, I am, nevertheless, decidedly opposed to *compulsory vaccination*.

I deem it unwise, unsafe, and, if not indeed unconstitutional, at least inexpedient at present.

It would be felt to be derogatory to the medical profession, and be found to be disparaging to the practice of vaccination.

Compulsory vaccination cannot be proved to be necessary, even if practicable, till more legitimate, consistent, and efficient measures for the repression of small-pox have been fairly tried in vain.

A consideration of the principal causes of the neglect of or resistance to the practice of vaccination among the poor and ignorant, will, I think, warrant these conclusions.

These causes may be thus briefly stated:—

i. Apathy and indifference to remote danger.
ii. Suspicion and distrust of a measure connected with the Poor Law authorities.

iii. Fear of imparting other diseases with the vaccine.

iv. Repugnance to the process, unless performed with lymph taken from a subject selected or approved by themselves.

v. Ignorant and absurd prejudices—often dignified as religious scruples—against the introduction of even a mild disease of brute origin, and a perverse preference for the “*real thing*”, however severe, because of human origin.

vi. Exaggerated notions of the inadequacy of vaccination to protect from small-pox.

vii. The facility and legal impunity with which, in the present defective state of the law, the absence of a public prosecutor, or a competent and efficient sanitary board, small-pox is suffered to exist, and be propagated from person to person and from place to place.

Vaccination really needs, deserves, and ought ever to be treated by the legislature as a beneficence, and administered as a boon; and not by a compulsory enactment of it, made odious to ignorance, already imbued with venial and unmitigated prejudice.

Like education, it should be facilitated, fostered, and encouraged, by liberal, gracious, and attractive measures.

On the other hand, small-pox deserves and requires to be treated as an unmitigated evil: as a great social pest; and its promoters and propagators as enemies dangerous to the public health.

The strong arm of the law can, and ought to be, effectually raised to repress and oppose its progress whenever and wherever it appears.

The eighth clause of the Vaccination Extension Act† provides a punishment, by summary process and conviction, for the wilful production, or attempt at production of small-pox by inoculation or infection.

But other provisions are required, and should be made clearly applicable to the negligent, reckless, or wilful exposure of the person, apparel, or any other infected article, either on the Queen's highway, or within any dwelling, or in any situation so as to endanger the health and safety of Her Majesty's subjects by the propagation of the disease.‡

The provisions of the Nuisances Removal and Infectious Diseases Prevention Act§ should be extended to persons, apparel, bedding, and every other article infected with small-pox.

And it should be lawful also to remove, like any other nuisance, to a suitable place of safety, and for appropriate treatment, any person labouring under small-pox, who, from contiguity or propinquity of residence, may by himself or herself directly, or indirectly, endanger the health and safety of a neighbourhood.

It should also be made compulsory on such persons, either by themselves, their friends, or attendants, to give immediate notice to the proper authorities of the existence of small-pox within their dwellings, in order that such removal, if practicable, may be promptly made; and if impracticable, that proper measures of precaution to warn and protect the public, may be summarily put in force.

Such dwellings, and all their inmates, should be placed under the observation and superintendence of the police or other local authority (acting under the direction and control of proper sanitary advisers), to carry out a rigid and efficient system of quarantine.

Pest-houses, or houses of reception, suitably appointed and properly situated, should be provided in every parish by the same authorities, under the same direction and control, for the reception of all classes of removable small-pox cases. And such authorities to be empowered to claim and recover reasonable fixed charges for such accommodation and treatment as the respective cases may require.¶

Such system of quarantine or seclusion to be rigidly enforced for a period of not less than forty-two days, from the development of the disease in ordinary cases, whether at the dwellings of the patients or in the pest or reception houses.

These or similar measures for preventing the spread of small-pox, while they do not abridge the liberty of the subject to choose or reject the casual disease for himself or his dependents, very properly insist that the exercise and enjoyment of that liberty—questionable as it is in the abstract—should not be dangerous, as it now daily is, to the rest of the community. Such measures are based on principles already recognised as just and legitimate, but which need further extension and development under competent authority and administration.

The rigid enforcement of them would not only signally discourage the maintenance, and effectually prevent the diffusion of small-pox, but would powerfully and speedily, though indirectly, promote the practice of vaccination.

The administration of such amended laws against small-pox propagation, as well as of all other matters relating to the public health, should be confided to a properly constituted central board of health. To such a board, also, should be delegated the administration of amended, or, more properly speaking, better devised laws for a system of national vaccination.

In the construction of such a system it ought to be always borne in mind that vaccination extension (not less than small-pox repression) is not merely an affair of a parish, a district, or an union, but a matter that concerns the entire community.

A national system of vaccination should be entirely free from the grave objections and obvious defects appertaining to the present system, and should avoid its parsimonious and distasteful arrangements.

It should appoint and endow in every city and town in the United Kingdom, possessed of the requisite population,‡ permanent stations furnished with properly qualified vaccinators and inspectors.

Such stations would attract a fair attendance for vaccination, of young and healthy subjects, from whom a good and regular supply of vaccine lymph, with proper management, could generally be procured for the public benefit, and for the assistance of vaccinators less favourably circumstanced.

There are various important details in the construction of such a scheme of national vaccination, requiring careful consideration: but to these I forbear more particularly referring at present.

I cannot, however, refrain on this occasion from the respectful but earnest expression of a hope that, in the consideration of a

* 3rd and 4th Vict., chap. 29; 4th and 5th Vict., chap. 32; 11th and 12th Vict., chap. 123.

† 3rd and 4th Vict., c. 29.

‡ Exposure of the person, while labouring under small-pox, on the Queen's highway, is an indictable offence; and of course, an offence never indicted. I have often fruitlessly attempted to incite the local authorities to this important but expensive duty.

§ Under proper sanitary regulations and control, such houses of reception might be made at other times subservient to the public health, by isolating the early cases of other infectious diseases in any locality.

Such houses are essential to an efficient system of sanitary police. They would save many lives, and materially abridge the present enormous annual expenditure caused by the propagation of small-pox and other infectious diseases.

‡ Not less than 60,000.

measure intended for the public good—the active and efficient agents of which must be found in the medical profession—liberality to that profession may supersede present and prospective injustice.

Thus by amended laws, an efficient sanitary police, the cordial and zealous co-operation of the medical profession, all the causes for the neglect of, or opposition to vaccination will, in due time, with the spread of intelligence, and the growth of better feelings, under more extended experience, gradually fade away and eventually disappear.

Small-pox will thus certainly and speedily be reduced to a perfectly manageable minimum, and exist only as a salutary stimulus to the practice of voluntary vaccination.

I am, etc.,

ROBERT CZEELY, F.R.C.S. Eng.,
Surgeon to the Bucks Infirmary.

THE EDINBURGH STRICTURE CONTROVERSY.

LETTER FROM JAMES SYME, ESQ., PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF EDINBURGH, TO THE EDITOR.

SIR,—In the nineteenth volume of the *Transactions of the Provincial Medical and Surgical Association*, I have just read the following passage of an "Address on Surgery, delivered at Oxford, in July 1852, by James Torry Héster, Esq.:"—

"If we cast our eyes beyond the Tweed, we see the melancholy exhibition of a city, celebrated through long ages as the birth-place of genius, torn by two rival factions and a petty squabble about the perineal section. It is not in these days a question whether the operation originated with Dessault or Syme, nor whether it be adapted for the cases in which it has been recommended. The ultimate condition of the patient is lost sight of in fierce animosity and personal invective, and the two leading surgeons have appealed to a Court of Law upon a question of truth. *Proh pudor!* It were vain to expect them to issue from the contest humbler, better, and wiser men. But should their repentance be ever so great, it will never efface the scandal such proceedings bring upon the profession.

"That such scenes may shortly cease to be enacted in the modern Athens, is my most earnest prayer; and as to ourselves, may we ever be delivered from envy, hatred, malice, anger, and all such pestiferous perturbations, which militate in no small degree against that tranquillity of mind so essential to the practice of the healing art. Were we to take a retrospect of the whole of this unhappy quarrel, in which direction must we turn for liberality or courteous bearing? Where is the trace of industry or of research? It is not even clothed in sparkling wit or glowing language. No! The terms which have been selected would have better suited the tavern or the hustings. If there be value in the practice recommended, we, as independent but anxious trustees of the public health, have a right to ask for a new series of experiments, under circumstances which would admit of no misunderstanding. Until then, no violence of language, no unblushing assertion, even in the form of advertisements in the public journals, will have weight to influence our judgment."

It is possible that the opinions of Mr. James Torry Héster, whose name is entirely new to me, may not possess the greatest weight; and it would be unreasonable to hold the Association responsible for all that is uttered by its annual orators. But when a statement such as that here quoted is made at a public meeting, and afterwards published in the *Transactions*, it acquires a stamp of approval which entitles it to pass current as deserving of credit. Now, having, throughout the whole discussion relative to the treatment of stricture by external incision, scrupulously avoided the use of language calculated to give personal offence; having resisted the urgent advice of my legal agent to prosecute the libellous calumnies on my practice which have been published in London, republished in Edinburgh, and anonymously circulated throughout the country; having been satisfied with denying the truth of these injurious allegations, and declined a controversy with persons whom I regarded as utterly unworthy of notice; having had the defensive course twisted into a charge of aggression which a jury on two different occasions without hesitation declared to be groundless; and having thus incurred the expense of more than £500 in maintaining a principle of treatment which I believe to be of practical value,—I did not expect to receive the censure of such a body as the Provincial Association, especially when the result of my efforts had been an addition to the resources of surgery. The faction opposed to it in Edinburgh never consisted of more than Dr. Mullar and his associate; and as the former, for rea-

sons which your ingenuity may probably suggest, has lately disappeared, the latter is now its sole representative.

I am, etc.,

JAMES SYME.

Edinburgh, April 16th, 1853.

[The *Transactions* are edited by the General Secretary of the Association; but neither he nor the Association is bound by the sentiments expressed by the different authors. Even in the Journal, the opinions contained in editorial articles are not necessarily Association opinions, inasmuch as the editorial articles are not subjected to any official censorship. EDITOR.]

NEWS AND TOPICS OF THE DAY.

LORD LYTTLETON'S VACCINATION BILL.

[House of Lords, April 14.]

The House went into Committee on this Bill.

Lord ELLENBOROUGH called attention to an inadvertency in the clause requiring notice to be given by the registrar. It directed notice to be given to the person who gave information of the birth. Now the person who came to register the birth might be almost unconnected with the father or mother, and yet by this bill it was proposed to impose upon that person the burden of giving notice to the parents or persons having charge of the child, under the penalty of fine or imprisonment. Some short time ago, he had told a registrar of two or three births of which that person was ignorant; and, if this act had been in force, he (Lord Ellenborough) would have been compelled, under a penalty of fine or imprisonment, to search out these persons, and to give them notice about the vaccination of the children. (A laugh.) He should propose, therefore, that instead of the provision he had alluded to, the registrar should deliver the notice of vaccination to the father or mother of the child, or to such other person as might have charge of it, and should, together therewith, deliver a notice of the time and place within the district in which he officiated at which the medical practitioner should attend for the purpose of vaccinating.

He had suggested that a penalty of five shillings should be enforced upon every schoolmaster or schoolmistress who, after a certain day, should admit into their schools an unvaccinated child. This, he thought, would be a fair requirement. Another provision which might be introduced was, to enforce the vaccination of emigrants; for where small-pox was once introduced into a ship where there were no means of vaccination, the destruction of every person who had not been vaccinated was often the consequence.

Their lordships had had a statement a few nights ago, and a very interesting one, as to the entire success of the compulsory system of vaccination in parts of Germany and Lombardy. What he desired to know, however, was, by what machinery that result had been attained—how it was they brought the person to the vaccinator, or the vaccinator to the person? A society had been formed in this country—he would not venture upon the extraordinary name by which they were designated—to investigate the cause and the extent of epidemics; and their view, he understood, was, that there should be in every union, or in every district, a public vaccinator, whose duty it should be, not to remain fixed in one place, but to go from house to house, to propose to operate upon those children or persons who he found had not been vaccinated. He thought the nearer this system was approached, the more perfect they would make this bill.

Lord LYTTLETON agreed to the amendment proposed.

The clause as amended was then agreed to.

On the clause regulating the fees payable,

Lord ELLENBOROUGH said, if, instead of giving the medical man an additional shilling for every case of vaccination, they gave the patient a shilling, there would be a rush to the vaccinator, and all the poor would, without the least reluctance, carry out the principle of vaccination.

[April 15.]

The report (on recommendation) of the above bill was brought up by Lord LYTTLETON. Some verbal amendments were introduced, and the report was received.

THE BUDGET.

[House of Commons, April 18.]

The CHANCELLOR OF THE EXCHEQUER (Mr. Gladstone) made his financial statement in a speech of five hours' duration. Our space only permits us to give a dry abstract of the main details.

In April 1852, Mr. Disraeli estimated the revenue for the year at £51,025,000, which in December he increased to £52,325,000, and at the end of the year the amount was £53,089,000, an increase of £1,404,000 on the estimate framed at the commencement of the year. The expenditure was estimated in April 1852, at £51,163,000, but the actual expenditure was only £50,782,000. The balance-sheet showed an actual surplus of £2,460,000. The question was whether or not the income tax should be parted with at once. By the imposition of certain other taxes, this tax might be got rid of; but the government did not recommend such a course. The amount of the tax—five millions and a half—large as it was, did not afford an adequate idea of the magnitude of the question. If the efficacy of this great engine were not destroyed, it would afford us the means, should hostilities unhappily break out, of at once raising an army of 300,000 troops and a fleet of 100,000 seamen, with other auxiliary aids, that would put this country in a condition to defy the world. Forty years ago, at a period of violent struggles, it enabled this country to raise an income above the expenses of the civil government, and in 1842, in a time of peace, its giant aid produced as remarkable results, and it might now assist us in completing the reform of our commercial system, and with ours that of other nations. Although called a tax, it was a complicated system of taxation. If he took the total receipts of the tax at £5,600,000, one twenty-eighth part would be £200,000. Now, lands and houses under schedule A paid no less than £2,400,000, or twelve twenty-eighths of the whole tax; and trades paid £1,800,000, or nine twenty-eighths; so that these two together paid three-fourths of the whole tax, while professions paid about one twenty-second part. It had been said that the same rate of tax ought not to be levied on precarious and realized incomes; but what were precarious and what realized? The relation between the payment on lands and trades would go a great way to solve the difficult question as to the justice of the tax. The real tax was paid by the land and houses. They paid 7d. in the pound uniformly on an income not assessed by the possessor, and without the smallest deduction in respect to the difference between gross and net income; whereas, if the present scheme of the tax was broken up, allowance must be made for repairs, insurance, law expenses, cost of management, arrears and abatements of rent. Taking this deduction at 10 per cent. upon £80,000,000, the gross income, it would be reduced to £87,200,000, which really bore the £2,330,000, the amount of the tax under that schedule. Then there were mortgages and settlements, which would reduce the income by at least £20,000,000, leaving it only £47,200,000, the net receipt of those beneficially interested in the lands and houses; so that the rate of the tax upon this species of property was 9d. in the pound, trades paying only 7d.—a proportion nearly equal to the 7d. and 5½d. proposed by Mr. Disraeli. If the basis of the tax were to be broken up, there would be a war of classes, and it was difficult to see where it would end. It had been said that the fair proportion which land should bear to trades was as four to three, and that was the relative proportion of the tax at present. As to the averaging of classes among themselves, he insisted that this was impracticable. Some trades were better than perpetuities, while others were not worth three years' purchase. As regarded the state of the case between land and trades, there was no sufficient ground for attempting to reconstruct the scheme of the tax. With regard to schedule C, including fundholders, he appealed to the House whether, if that schedule stood alone, it would not be an argument against breaking up the tax. Some rational construction must be given to the words of the Loan Act. The proposal to levy the tax upon the capitalized value of the income was one which could not with honour be adopted by the British Parliament. At present, only one-third of the public debt was held on sole accounts, indicating, generally speaking, absolute property; and the remaining two-thirds were held on joint accounts by persons not in their own right. Professions paid one twenty-second part of the tax, and public feeling recommended a change of this part of the scheme; and he warned the committee of the more than Herculean task that must be undertaken if an attempt be made to reconstruct the tax because of so limited a case as this schedule. There had been a most earnest desire on the part of the Government to consult the public feeling on the subject of this tax; the difficulties were insuperable. These were the views of the Government regarding the income tax, a gigantic engine, but the circumstances attending it rendered it impossible to maintain it as a portion of our permanent fiscal system. One thing he hoped the House would not do—namely, nibble at it, and try one experiment after another. Whatever was done with it should be bold, intelligible, and decided; pal-

tering with it would jeopardise one of the most valuable of our fiscal resources. Government propose to abolish it altogether after a gradual diminution for seven years. In 1855 it shall drop to 6d. in the pound, and in 1857 to 5d., where it is to stand till 1860, when it is finally to expire. Meanwhile it shall be levied to the extent of 5d. on all incomes down to £100, and shall be extended to Ireland, also at the same rate. Duty on tea by a shilling a pound; viz., from 2s. 2½d. a pound to 1s., spreading the reduction over three years. The duty on soap, producing a net sum of £1,111,000, he proposes to abolish at once and altogether. The duties on many other articles of domestic consumption are diminished or abolished. Receipt stamps are to be abolished, a Queen's head franking a receipt as it does a letter. The stamp duty on life assurance is to be reduced; and those on attorneys' certificates respectively from £12 and £9, to £8 and £6; and the stamp on admission from £120 to £80. The duty on advertisements it is proposed to reduce from 1s. 6d. to 6d., and to fix the duty on each newspaper at one penny a copy, without regard to its size, and without imposing an additional duty on supplements.

ADVERTISEMENTS.

The Middlesex Hospital School of

MEDICINE.—The SUMMER SESSION will commence on MONDAY, MAY 2nd, 1853.

Fee for attendance on all the Lectures and Hospital Practice required by the Royal College of Surgeons and the Society of Apothecaries, £75, which may be paid by instalments of £30 at the beginning of the First Session, £30 at the beginning of the Second Session, and £15 at the beginning of the Third Session. Fee for Eighteen Months' Attendance on the Medical Practice, and Three Years' Attendance on the Surgical Practice of the Hospital, £30.

FORENSIC MEDICINE—DR. GOODFELLOW, Nine to Ten a.m.

MIDWIFERY—DR. FRERE, Ten to Eleven a.m.

BOTANY—MR. BENTLEY, Eleven to Twelve a.m.

PRACTICAL CHEMISTRY—MR. TAYLOR and MR. HEISCH.

(Fee for Pupils of the School, £2 2; for others, £1 4.)

MATERIA MEDICA—DR. STEWART, Three to Four p.m.

DR. VAN DER BYL will give a COURSE of LECTURES on PRACTICAL HISTOLOGY and the APPLICATION of the MICROSCOPE to the INVESTIGATION of DISEASE. The Class will meet for two hours twice a week. Fee, £2 2.

The ANNUAL DISTRIBUTION of PRIZES will take place on WEDNESDAY, MAY 4th, at Half-past Three, when the LORD BISHOP of OXFORD will preside.

Prospectuses and further particulars may be obtained on application at the Hospital.

To be disposed of, a long-established

and HIGHLY RESPECTABLE RETAIL, situated in a first-class Neighbourhood at the West End, lately in the occupation of a Surgeon, and offering unusual advantages to a Surgeon commencing practice. Shop and Fittings handsome and in good repair. The returns are £400 per annum, but susceptible of much improvement. Apply to MESSRS. HODGE and HOLMES, Blackman Street, Borough.

TO PHYSICIANS, SURGEONS, AND DRUGGISTS.

Brown's Cantharidine Blistering

TISSUE, prepared from Pure Cantharidine. An elegant preparation, vesicating in much less time than the Emp. Lytta P. L., easily applied and removed, and will not produce strangury or troublesome after-sores. It has received the sanction and commendation of many of the most eminent Practitioners in the kingdom. In Tin Cases, containing twelve feet, 6s. 6d.; and small Cases of six square feet, 3s. 6d. each.

BROWN'S TISSUE DRESSING, an elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, and may be called a companion to the above. In Tin Cases, containing twelve square feet, 1s. 6d. each.

Extracts and Editorial Note from the "New York Journal of Medicine".

March 1st, 1850.

"BROWN'S CANTHARIDINE TISSUE.—It presents peculiar claims to our notice in the inflammatory diseases of females and children, in whom the unpleasant consequences which so often follow the application of the Emp. Cantharides are most apt to occur. We have found it a reliable and peculiarly safe vesicant, and from the many trials we have given it, we are satisfied that it deserves the attention of the Medical Profession.

"Accompanying this article is a very simple and neat dressing."

From the "Medical Examiner and Record of Medical Science" for May 1850, Published in Philadelphia.

"We have received from Mr. Geo. D. Phelps, of New York, specimens of BROWN'S CANTHARIDINE BLISTERING PLASTER AND DRESSING, with which our readers are doubtless familiar as a new and exceedingly neat preparation, easy of application, and certain in their effects. We have given them a fair trial, and find they fully answer our expectations."

Army Medical Department, January 10, 1847.

"The Principal Medical Officer of the General Hospital, Fort Pitt, Chatham, reports that MR. BROWN'S BLISTERING TISSUE has been used extensively in the Military Hospital, has been found effective as a vesicatory, when carefully applied, and has not been productive of any degree of strangury."

"ANDREW SMITH, M.D.,

"Mr. T. B. Brown, Druggist, "Deputy Inspector-General of Hospitals. "Handsworth, Birmingham."

Prepared by T. B. Brown, Pharmaceutical Chemist, 42, Admiral Terrace, Vauxhall Bridge Road, London; and Sold by the Sole Consignee, MR. WILLIAM BAILEY, Wolverhampton, and all wholesale and retail Druggists and Medicine Agents throughout the British Empire.

NOISELESS RINGS.

Gutta Percha Curtain and Cornice

RINGS.—These Rings have been much approved by the Faculty, particularly for nervous and aged persons. Owing to the peculiar properties of Gutta Percha, these rings do not make a noise when drawn along the pole or rod. The following sizes may be had either with or without loops:—Sizes, 1 inch diameter, 1½ inch ditto, 2 inch ditto, 2½ inch ditto, 3 inch ditto, 3½ inch ditto.

TUBING, LINING FOR TANKS, ORNAMENTAL MOULDINGS, &c., manufactured by the **GUTTA PERCHA COMPANY**

(Patentees), 18, Wharf-road, City-road, London.

Osteological and Dental Repository.

45, Museum-street, Bloomsbury, London. **JOHN HARNETT** begs most respectfully to call the attention of Lecturers, Students, and Gentlemen connected with the Medical Profession, to his large and select Stock of **Anatomical Preparations**, consisting of Skeletons, loose and articulated Skulls, Hands and Feet, Vertebrae, and Loose Bones, at the lowest possible prices.

Horne, Thornthwaite, and Wood,

OPTICIANS AND PHILOSOPHICAL INSTRUMENT MAKERS, 123 and 121, NEWCASTLE STREET, LONDON.

ELECTRO-GALVANIC MACHINES, £3.3, £5.5, £8.8, and upwards.

ACHROMATIC MEDICAL MICROSCOPES, £5.5, £7.10, and upwards.

URINOMETERS, 4s. 6d., 10s. 6d., 15s., and upwards.

PATENT PANTOSCOPIC and other SPECTACLES, accurately adjusted to the condition of the Eye by **Smee's Ophthalmometer**.

THE

FIRST FESTIVAL OF THE MEDICAL BENEVOLENT COLLEGE

WILL TAKE PLACE AT THE

FREEMASONS' TAVERN, on WEDNESDAY, THE 4TH OF MAY NEXT.

THE PRESIDENT, THE EARL MANVERS, IN THE CHAIR.

THE FOLLOWING NOBLEMEN AND GENTLEMEN HAVE KINDLY CONSENTED TO ACT AS STEWARDS ON THAT OCCASION:

Egmont, Earl of St. James's Place
 Carlisle, Earl of
 Acland, H. W., M.D., Radcliffe Librarian, Oxford
 Aldis, Chas. J. B., M.D., Chester Terrace, Chester Sq.
 Anderton, James, Esq., New Bridge St., Blackfriars
 Arden, Richard F., Esq., Sunbury Park, Middlesex
 Bacon, John, Esq., Portugal Street
 Barron, E. Enfield, M.D., St. Thomas St., Southwark
 Bentley, J. Esq., Portland Place
 Bleock, Charles, Esq., Warminster
 Bowling, John, Esq., Hammersmith
 Brinkman, Sir Theodore, Bart.
 Brown, Wilson, Esq., Bath
 Brown, Isaac Baker, Esq., Connaught Square
 Bull, Henry Graves, M.D., Hereford
 Burrows, George, M.D., F.R.S., Cavendish Square
 Bury, George, Esq., Whetstone
 Cabbell, Benjamin Bond, Esq., M.P., F.R.S.
 Carden, H. D., Esq., Worcester
 Carr, Wm., Esq., Lee Park, Blackheath
 Chippendale, John, Esq., New Cavendish Street
 Churchill, John, Esq., Princes Street
 Clark, Sir James, Bart., M.D.
 Clarke, Sir Charles M., Bart.
 Clayton, James, Esq., Percy Street
 Clifton, Nathaniel, Esq., Islington
 Cocks, T. Somers, Esq., M.P.
 Colledge, T. R., M.D., F.R.S. Edin., Cheltenham
 Conolly, John, M.D., Hanwell
 Cooke, Wm., M.D., Trinity Square, City
 Cooper, G. F., Esq., Brentford
 Cotton, Wm., Esq., F.R.S., Leyton
 Cotton, Charles, Esq., Lynn, Norfolk
 Coulson, Wm., Esq.
 Green, Joseph Henry, Esq.
 Luke, James, Esq.
 Pilcher, George, Esq.
 South, John Flint, Esq.
 Travers, Benjamin, Esq., F.R.S.
 Coulthurst, John, Esq., Clifton
 Cowley, John, Esq., Oxford Terrace
 Davies, Henry, M.D., Duchess Street

Members of the
 Council of the
 Royal College
 of Surgeons

Day, Horatio, Esq., Isleworth
 Du Pré, George, Esq., M.P.
 Faoster, Sylvester, Esq., Folkestone
 Edgecumbe, Richard D., Esq., Shaftesbury Crescent
 Elliott, Charles, Esq., F.R.S., Portland Place
 Evelyn, W. J., Esq., M.P.
 Eyles, J. S., Esq., St. Andrew's Court
 Eyre, Sir James, M.D.
 Fergusson, Wm., F.R.S., George Street, Hanover Sq.
 Fincham, George, Esq., Spring Gardens
 Fisher, J. W., Esq., Grosvenor Gate
 Forbes, John, M.D., Old Burlington Street
 Freshfield, James W., Esq., M.P., F.R.S.
 Fuller, Henry P., Esq., Piccadilly
 Gadesden, James, Esq., "Ewell Castle", Surrey
 Gardner, Wm. Henry, Esq., Gloucester Ter., Hyde Park
 Godrich, Francis, Esq., Brompton
 Gosling, Robert, Esq., Fleet Street
 Grainger, Richard D., Esq., F.R.S., Highgate
 Gream, George Thompson, M.D., Upper Brook St.
 Gregson, S., Esq., M.P.
 Holland, Sir Henry, Bart., M.D., Brook Street
 Halley, Alex., M.D., Queen Anne St., Cavendish Sq.
 Haumer, Colonel
 Hare, Rev. Dr., Chaplain of Middlesex Hospital
 Hargraves, Isaac, Esq., Tunbridge Wells
 Headland, Edward, Esq., Guildford Street
 Iliff, Wm. Tiffen, Esq., Newington
 Jones, Arthur O'Brien, Esq., Epsom
 Kingston, W., Esq., New Bank Buildings
 Labouchere, John, Esq., Birch Lane
 Laves, John, Esq., Great George Street
 Le Marchant, Sir Denis, Bart.
 Littler, John W., Esq., Lower Edmonton
 Locock, Charles, M.D., Hertford Street, Park Lane
 Lord, Charles F. James, Esq., Hampstead
 Lunn, William Joseph, M.D., Hull
 Martin, James Randall, Esq., F.R.S., Grosvenor St.
 Martin, Peter, Esq., Reigate
 May, George Parker, M.D., Maldon
 McWhinnie, A. M., Esq., New Bridge Street
 Merriman, John, Esq., Kensington

Moore, Joseph, M.D., Saville Row
 Morris, John Carnac, Esq., Mansfield Street
 Nisbet, Dr., Greenwich
 Philipps, James, Esq., Leicester
 Parrot, John, Esq., Clapham
 Phillips, James, Esq., Bethnal House Asylum
 Pinching, Charles John, Esq., Gravesend
 Pollock, Robert James, Esq., Kensington
 Poynder, Edwin, Esq.
 Price, Allan Forri, M.D., Deptford
 Reed, Frederick George, M.D., Hertford
 Roberts, John, Esq., North Buildings, Finsbury Circ.
 Roots, Henry Shuckburgh, M.D., Russell Square
 Routs, Wm. Sudlow, Kingston-on-Thames
 Rowe, George Robert, M.D., Cavendish Square
 Scannell, D., Esq., Chapel Street, Belgrave Square
 Scobell, Rev. Edward, Blandford Street
 Scott, Sir Sibbald D., Bart.
 Scott, Sir Claude E., Bart.
 Self, William, Esq., Commercial Road
 Sloman, Samuel George, Esq., Farnham
 Stedman, James, Esq., Guildford
 Stilwell, Arthur, M.D., Queen Street, Mayfair
 Stilwell, George, Esq., Epsom
 Sutherland, A. J., M.D., Richmond Terrace
 Symonds, J. A., M.D., Bristol
 Thistleton, Augustus U., Esq., Burton St., Burton Cres.
 Thompson, Theophilus, M.D., Bedford Square
 Thorne, Richard L., Esq., Upper Belgrave Place
 Todd, Robert B., M.D., Brook Street
 Towers, Wm. Colburn, Esq., Montague Square
 Waddington, J., Esq., Margate
 Ward, Joseph, Esq., Epsom
 Warrander, Sir John, Bart.
 Weiss, F. F., Esq., Chester Terrace
 Westall, Edward, Esq., Croydon
 Whitman, J., Esq., M.P.
 White, W. F., Esq., St. John Street
 White, George, Esq., Epsom
 Wilkinson, Frederick E., Esq., Sydenham
 Wilson, James Arthur, M.D., Dover Street
 Woollaston, Robt., Esq., Gloucester Ter., Hyde Park

Gentlemen who purpose attending the Festival are informed that Tickets, which may be had of the Secretary, should be procured before the 31st instant. Tickets One Guinea each.
 OFFICE,—4, HANOVER SQUARE,
 April 18th, 1853.

By order of the Council,
HENRY TUDOR DAVIES,
 Hon. Secretary.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XVII.

LONDON: FRIDAY EVENING, APRIL 29, 1858.

NEW SERIES.

PROFESSOR MILLER, of EDINBURGH, the author of a communication in our last number, has, we find, been confounded by several correspondents with DR. F. G. W. MULLAR, the pursuer in the recent jury trial at Edinburgh, "Mullar against Robertson and others, conductors of the *Monthly Journal of Medical Science*". As MR. MILLER and DR. MULLAR are different gentlemen, more than one correspondent will see the propriety of our declining to publish his letter.

THE PROSPECTS OF MEDICAL REFORM.

We hoped to have been able to-day to report some progress in the Medical Reform question; but we regret to find that as yet Lord Palmerston has not communicated with the Reform Committee. Mr. Hastings has in these circumstances written to his lordship, and an immediate reply may be expected. In the mean time, it is our duty to state that great impatience is felt by the profession throughout the country; and that a fear is expressed by many that the session of Parliament may be allowed to pass away without any Bill being brought forward, in consequence of present silence being imputed to apathy, and not to its true cause—uncertainty as to the exact position of affairs. As there is no Bill before Parliament, it is not competent for us to petition for any specific measure; but it might be well for us to guard against a future charge of indifference, by petitioning generally for such a measure of medical reform, as will embrace the three great objects for which our ASSOCIATION has contended, and is now contending, viz. :—

- I. UNIFORMITY OF QUALIFICATION:
- II. EQUAL RIGHT TO PRACTISE THROUGHOUT THE UNITED KINGDOM: AND
- III. REPRESENTATIVE COUNCILS FOR THE GOVERNANCE OF THE PROFESSION.

THE INCOME TAX.

MR. GLADSTONE, in the exposition of his financial scheme, is represented as having used the following words, by way of illustrating his argument that the life annuitant is entitled to an exemption from the tax on income, at least equally with the professional man :—

"When you come to life annuitants, you then deal with the desolate widow, with the orphaned daughter, with the defenceless woman, whose right it is to expect at your hands justice, tenderness, and protection. Are their incomes precarious, or are they not? I will take some lady who has been bred in the lap of luxury, and who then, upon the death of her parent, finds herself with the interest of £5000 or £6000 to live upon for the remainder of her days. I want to know whether that is to be subjected to the higher tax as an income from realized property? Will you, then, tell me, that upon the daughter and the widow you will lay that exceptional tax, and yet speak of doing justice, because you put the higher tax upon her, in order

that you may put the lower tax upon bankers and brewers, and physicians and lawyers?"

The accomplished Chancellor of the Exchequer has been trained in a school where rhetorical skill has always been successfully taught, and its value fully understood. No one, therefore, is better acquainted with the best method of introducing to his hearers an appeal to the feelings: no one more likely to observe the rule, that no address to the passions should be delivered directly as such, but that the best way of making a demand on the sympathies of the audience, is to illustrate the general argument by narrating a case in point; and, moreover, if the object be to excite pity, that the phraseology should be epigrammatic and suggestive, rather than copious and clear. There is, however, such a thing as overshooting the mark. We shall endeavour to show (as the question dips deeply into our professional pockets) that the Chancellor's argument is fallacious, and his illustration consequently of no avail; although, in so doing, we run the risk of being charged with presumption for daring to measure swords with a Chancellor of the Exchequer, and with want of gallantry for endeavouring to disprove the plea of the ladies.

Two things particularly strike us in reading Mr. Gladstone's statement; first, the careful suppression of all allusion to the causes for which taxes on income are imposed; and second, the including "physicians" in the same category with "bankers, brewers, and lawyers". As the first circumstance materially bears upon the second, we shall proceed to discuss them briefly in the order in which they stand.

For information on the general principles of taxation, we refer our readers to Adam Smith's well-known work on the *Wealth of Nations*. It is sufficient for our present purpose, to state the axiom, that *every tax should be viewed as the purchase-money paid for equivalent advantages*. Now, the advantages which are derived from taxation are clearly of a protective character; it is therefore at once obvious, that the life annuitant is especially concerned in the security of the fund from which his or her annuity is derived, and that fleets and armies are necessary to defend the Treasury from dangers without, as well as that courts of law must be maintained for the administration of justice within the realm. But how can this principle be made to apply to the protection of incomes derived from no such source? We confess we are driven back upon our original proposition, and must ask how the professional man can view the income tax as *the purchase-money paid for an equivalent advantage* in the same ratio as the annuitant, when the one pays for the protection both of the public generally, and of the *principal* of his own income in particular, whilst the other, so far as his immediate income is concerned, has no principal to protect? The conclusion at which the Chancellor arrives would be perfectly just, if the portion of the case which he has thought proper to make known to us were the whole of it; but since he has kept in the background a material element in the calculation—

namely, the principle upon which the particular tax in question is levied—a principle which, if brought forward, must vitiate the result—we cannot but think that logicians will consider his argument entitled to take rank among the fallacies of non-observation.

We now address ourselves to the second division of our subject; and here we wish carefully to avoid the imputation of seeking to exempt our profession from the common burdens imposed by the necessities of government. We are each and all of us bound to contribute our share to meet the public expenditure, and to perform those acts of citizenship which are within our power: but there are conditions annexed to the duties of the medical man which separate his fortunes from those of all other men, and make him a person of no inconsiderable consequence, and liable to be called upon to exercise the most arduous, as well as the most satisfactory functions of his office, at a time when all other classes of the community are involved in anarchy and confusion. Let it be remembered that the art of healing is an art of peace, even in the midst of war; and that it possesses a quality like that of its companion, mercy:

"It droppeth as the gentle rain from heaven
Upon the place beneath. It is twice blessed;
It bleaseth him that gives, and him that takes."

For it is not only true that we practise a profession which is of service to all people, but that this profession is called into action at all times and under all circumstances—nay more, that the virtues of our craft to the eye of the multitude shine brighter by the watch-fires of the bivouac, and among the flames which consume the besieged city, than when viewed by the light of a domestic fire-side, which has never known the horrors of war.

We have no desire to push this subject too far, or even to carry out our argument to its fair and legitimate conclusion. It is enough to say, that even in our own times the services of medical men have been honoured and esteemed during revolutionary periods, when the hearts of all were failing them for fear, and when ruin was staring them in the face. We heartily pray, for the sake of our altars and our hearths, that we may never be called upon to practise the science of medicine and surgery under the fire of an invading army, or amidst the abominations of a civil war; but we would have the legislature to do us justice, and to understand that no social volcano which crumbles to dust the institutions of other men can shake the integrity of medicine as a profession; for it is while such storms are raging, that medicine appears in her true character and brightest colours. When emperors and kings are tottering on their thrones, the good deeds of Medicine proclaim, that her officers hold their commissions from the King of kings.

THE CHANCELLOR OF THE EXCHEQUER ON MEDICAL FEES.

In the *Times* of Monday last, a letter is reprinted which the Chancellor of the Exchequer has addressed to Mr. Joseph Lloyd Phelps, a clerk in Birmingham, on the subject of the income-tax. We direct the attention of our readers to this interesting communication, for two reasons; first, because it exhibits a most kindly feeling to all classes of the community on the part of the important functionary from whom it proceeds; and secondly, because Mr. Gladstone has most candidly and sagaciously exhibited in a new light the value of the services of medical men to a large section of the general public.

In one part of his letter, Mr. Phelps complains that the clerk with a salary of £100 a year will, by the proposed measures of the Government, be in no way relieved "on house rent, on clothes, on meat, on flour, on coals, on education of children, on medical attendance, on borough and parochial rates."

In his reply, Mr. Gladstone refers to the question of medical attendance and makes the following significant remarks:—

"You say medical attendance is not cheapened. Surely, medical attendance has since 1842 been virtually and really cheapened to you, if medical men (as has been the case) have been called upon, without any increase of their fees, to pay income-tax in order to reduce the price of articles, of which persons of £100 a year are, relatively to income, larger consumers than they themselves who have paid the tax."

There is no occasion for us to offer a comment on this extract. It plainly indicates that the claim of the medical man to be freed of the burden of the income-tax has not passed unheeded by the Chancellor of the Exchequer; and it strengthens the hope, expressed in our last number, that the numerous petitions which the profession is now laying on the floor of St. Stephen's may not prove altogether useless.

GALVANIC QUACKERY IN EDINBURGH.

THE remarks which we made a fortnight ago upon Pulvermacher's Chain, and the advertisements of its proprietor, have brought us a number of very curious communications illustrating the subject of second-hand advertising.

From Edinburgh, we learn that the Galvanic Quackery is there flourishing as luxuriantly as in London. A person of the name of Harthill fills columns of the front page of the newspapers with puffs in the usual extravagant style and phraseology adopted by universal curers. In place of the "Hydro-Electric Chain of Pulvermacher", we have the "Halsean System of Galvanism without Shock or Pain". The following is an extract from a very long advertisement which appears regularly in the *Caledonian Mercury*.

"The Halsean System of Galvanism gives neither shock nor pain; and whether, as regards the apparatus employed, or the mode of its application, it differs entirely from the electrical influence of rings, chains, and small galvanic batteries. HALSE'S Pamphlet on Galvanism, together with Mr. HARTHILL'S List of Cures, may be had gratis (or post free for two stamps), at 7, Castle Street, Edinburgh. They contain particulars of cures in obstinate cases of Rheumatism, Sciatica, Paralysis, Nervousness, Dyspepsia or Indigestion, Pains in the Head, Spine, and Limbs, Asthma, Neuralgia, Lumbago, Tic-Doloureux, Liver Complaint, certain cases of Deafness and Dimness of Sight, Spinal Complaints, General Debility, Costiveness, Stiff Joints, Female Complaints, Deficiency of Nervous Energy, Rheumatic Gout, and all sorts of Nervous Disorders. As a remedy for Diarrhoea, and a preventive of Cholera, HALSE'S Galvanism is invaluable. Patients can be Galvanised at their own residences when required. Terms moderate."

The Halsean quack of the northern metropolis is evidently omnivorous: he lies in wait for all sorts and conditions of invalids, as appears from the preceding extract: and if the subjoined *morceau* (which constitutes a part of the advertisement from which we have quoted) be not a forgery, he can boast of having patient and puffery combined in a fellow of the Royal College of Physicians, Edinburgh. Mr. Meinig can show nothing to match this.

IMPORTANT TESTIMONIAL.

From one of the most eminent medical men in Scotland.

"I have much satisfaction in stating that I was under Mr. Harthill's care for some weeks, with considerable advantage in diminishing many very unpleasant symptoms of oppression of the chest, and general weakness. His skill, attention, and kindness, were extreme; and I regret that I was prevented, by pressure of business, from continuing longer under his care. I mean speedily to renew the galvanic treatment, which, as applied by him, is most safe and beneficial, and in a greater variety of cases than is usually supposed—whether of mal-organisation or function of different organs—it strengthens the nervous and circulating systems, and in palsy, weakness of the spine, and nervous complaints, often performs miracles. (Signed)—JOHN THATCHER, M.D., Fellow of the Royal College of Physicians, etc., Edinburgh, 14, Picardy Place, May 8th, 1852.

When next Dr. Thatcher is able to emancipate himself from the "pressure of business", he might with advantage submit his case to his college. We feel convinced that it is their duty to administer to him a more legitimate restorative than Halsean galvanism.

THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY AND THE DISCUSSION OF TUESDAY ON URETHROTOMY.

WE have to-day reported at some length an interesting discussion which took place on Tuesday, in the Royal Medical and Chirurgical Society, upon the reading of a paper by Mr. Syme of Edinburgh, on the treatment of obstinate stricture of the urethra by external incision. The attendance of hospital surgeons, we regret to state, was not large—smaller, we think, than on an ordinary occasion when no subject of special surgical interest is expected. An hospital appointment surely carries with it an obligation to communicate experience when that experience is required to elucidate a new or doubtful method of treatment; and it therefore cannot escape notice that on Tuesday night Guy's, St. Bartholomew's, the London Hospital, King's College, University College, the Westminster, Charing Cross, and St. George's Hospitals, were not represented in the debate.

THE "CHURCH AND STATE GAZETTE" v. THE MEDICAL PROFESSION

By a mere chance, a copy of the *Church and State Gazette* or *Churchman's Family Newspaper* of Friday, April 22nd, fell under our notice. Casting our eye over the leading articles we read as follows:—

"The remarks made by Mr. Gladstone on incomes derived from the funds, and those made in the exercise of lucrative professions and trades will find an echo in every honest breast. The majority of fundholders—we allude especially to bona-fide investors who do not speculate but who live on the interest of their investments—may be said to consist of persons who have toiled long, and spared and saved, in order that their old age might not be entirely defenceless or desolate. To make these pay a greater proportional amount of income tax than the medical man or the lawyer, who lives like a prince, scorns to save, and leaves his family to the charity of friends, would be a gross act of injustice. Generally speaking, 'professional men' are the Bedouins of civilized society. They enforce a most extravagant rate of remuneration; and to supply this on the side of the public, renders cold many a hearth, extinguishes many a fire, and condemns to utter desolation entire households. It is a saying in France, that fashionable medical men are assassins who ride in gay carriages; we

will not say the same of those nearer home; but we will say that to save such from income tax, while the latter is left to weigh heavily on poor and unprotected female fundholders, would be an amount of injustice in which none would willingly acquiesce—save perhaps the professional gentlemen themselves."

Let us briefly examine one or two points in this passage.

In the first place, it is written under the assumption that the rich or "fashionable" portion of the profession are agitating for an exemption from the income tax, at the expense of the poor fund holder. A passage from a letter which we received this morning from a country surgeon, may throw some light upon this part of the subject, and tend to show that we are not advocating the cause of the rich, but of the hard-working and ill-paid medical man.

"For many years I had to work six large parishes in the Union in which I live; and although I could prove that these parishes cost me from £50 to £100 a-year, over and above the salary which I received, yet for many years I paid income tax upon the entire salary I received from the Union. Again, when I took occasion to appeal against a surcharge made upon my return, the law was laid down to me, that if fifty of my patients, owing me £10 each, were to march off to America without paying me, I was liable to pay income tax, less deductions, upon the £500; in other words, that my income was to be calculated upon what I booked, and not upon what I received. Now is this what is termed a just incidence of taxation?"

Does the Editor of the *Church and State Gazette* mean to say that this is fair or honest, when compared with the sevenpence in the pound taken from the £1,200 a-year, paid to a clergyman for being "in residence" for three months in the year as a canon in one of our cathedrals? We might, were we to descend to the literary platform of the *Church and State Gazette*, easily retort upon the writer of the passage which we have quoted, by saying that these incomes of £1,200 a-year would make warm many a naked fellow-creature, or feed many a hungry and starving wretch, in the parishes from which these stipends are wrung; but we would deserve the condemnation of every right-thinking gentleman were we to follow such a course of argument.

But what does this writer mean by saying, that the medical man "scorns to save"; and "leaves his family to the charity of friends"? Does not the assertion belie the writer's words, that such men exact "an extravagant rate of remuneration"? There are too many, alas! of the families of medical men who are left destitute, and in some cases this destitution is the penalty of improvidence; but to say that the majority of medical men live extravagantly or recklessly is untrue; and to conclude that this is the case because many of their families are left destitute, is a cruel misstatement.

And what, may we ask, does the *Church and State Gazette* mean by quoting a story supposed to be rife in Paris about medical men, and by then leaving his readers to infer, that "fashionable medical men" are "assassins who ride in gay carriages"? Is this the temper which ought to influence the organ of one profession in criticizing even the faults of another? Is this "the charity which thinketh no evil"? Can we recognize in our clerical contemporary any attempt to conform to that character which ought to distinguish men who claim to be the direct successors of the Holy Apostles, and whose divine errand it is to proclaim to the world the gospel of peace, goodwill, and salvation? Nay, do not the mere requirements of gentlemanly, not to speak of Christian language, forbid the bandying of such epithets as "plunderer" and "assassin"?

ORIGINAL COMMUNICATIONS.

HINTS ON AUSCULTATION, WITH A VIEW TO THE SIMPLIFICATION OF TERMS AND ARRANGEMENT.

By THEOPHILUS THOMPSON, M.D., F.R.S., Physician to the Hospital for Consumption and Diseases of the Chest.

THE present century has been a period of remarkable progress, as respects the diagnosis of thoracic disease. A glance at standard works published less than thirty years since will exhibit striking evidence of the truth of this assertion.

It may be sufficient to instance the remarks of Dr. Mason Good, in the second edition of his work on the *Study of Medicine*,* published about the period when Dr. Forbes first called the attention of the profession in this country to the observations of Laennec. The chapter on Dropsy of the Chest, in Dr. Good's work, affords material of much interest, viewed in relation to the present mode of investigation. In reference to dropsy of the mediastinum, pleura, pericardium and lungs, Dr. Good observes: "These can never with any degree of certainty be distinguished from each other till after death"; and "those who are desirous of examining into the curious and often contradictory signs by which these several forms of pectoral dropsy have been attempted to be discriminated by various writers, may turn with advantage to Sir J. Maclean's work upon the subject". He adds (p. 407): "The only decisive symptom in this disease is the fluctuation of water in the chest, whenever it can be ascertained; for several of the other signs are often wanting, or, in a separate state, are to be found in other complaints of the chest as well as in dropsy, more particularly in asthma and empyema."

Every reader of this JOURNAL is familiar with the change effected in this department of inquiry since these remarks of Dr. Good were penned. It must, however, be acknowledged that the advantages which the new modes of investigation offer, have not always been realized; partly in consequence of a tendency to regard the phenomena observed by means of auscultation as necessarily intricate and complicated. Such an idea is surely founded on misapprehension. The soft silky sound, heard on listening to the chest of a healthy individual in the act of breathing, cannot be mistaken. Every practitioner must have had frequent occasion to observe this silky murmur superseded by bubbling sounds, when, in consequence of affections of a catarrhal character, the air in its entrance and its exit passes through the secretions with which the air passages are occupied: the sound being necessarily modified according as this secretion is confined to bronchi of considerable calibre, or diffused through the smaller tubes, or the aerating tissue of the lungs. When the smooth expansion of this tissue is prevented by causes extrinsic to the cells, and the air in expiration does not pass through secretion, the sound produced has not a bubbling character, and may be confined to the period of inspiration. In this way, varieties of crackling and crepitation sounds originate.

When, in consequence of thickening of the investing membranes, or the presence of any partial obstacle, the calibre of the bronchi is altered, vibratory sounds are induced, which may be grave or acute, according to the diameter of the passages affected.

The simple view thus presented sufficiently represents the principal circumstances, which require to be considered in the practical application of auscultation to those diseases of the chest, in which difficulties are most frequently experienced and errors most readily committed.

It must be acknowledged that familiarity with the practice of auscultation requires for its attainment considerable devotion of time and labour; but it will scarcely be disputed that, in addition to the difficulties inherent in the subject, others have arisen: 1st. From attempted refinements, not

authorized by existing phenomena; 2nd. From the use of terms, either inaccurate, or not sufficiently distinctive. The first of these mistakes tends to render the art of auscultation unattainable: the second introduces confusion, which is often worse than ordinary error, because it is a form of error difficult to correct. I do not expect in the present communication altogether to avoid these defects; but it will be my aim to describe only sounds which can be readily recognised, and to select such terms as shall express as marked a difference as possible between sounds differing in their character and practical significance. Whilst avoiding any unnecessary alteration of terms which have been sanctioned by general usage, I shall not scruple to displace those which are obviously inaccurate or calculated to induce practical error.

In attempting to form systematic classifications of auscultatory phenomena, confusion has often arisen from the circumstance, that some sounds have been designated according to the impression made on the ear, and others in subserviency to some theoretical idea regarding their mode of origin. Thus, for example, the crepitant rhonchus, although from its name implying a sound dry in character, is yet placed by some authors amongst moist rhonchi, from the supposition of its being due to the presence of secretion. If it be considered convenient and expedient to make an arrangement founded on the nature of the impression made on the ear, whether of dryness or of moisture, the crepitant rhonchus should certainly be placed in the first of these divisions: and my own view of its cause would induce me on theoretical grounds to consider this its appropriate place.

The following arrangement may be considered to afford a simple and comprehensive exhibition of the most remarkable sounds, according to the principle of classification which has just been noticed.

TABLE I.—*Rûles or Abnormal Sounds produced within the Lungs, arising from Morbid Secretion.*

		Heard in	
		Inspiration.	Expiration.
I. Dry.	1. Sibillant	—	—
	2. Sonorous	—	—
	3. Crackling (or dry click)	—	—
	4. Crepitant	—	—
	a. Primary (or fine crepitant)	—	—
II. Humid.	b. Secondary	—	—
	1. Bubbling (or subcrepitant, or moist crepitant, or mucocrepitant)	—	—
	2. Mucous	—	—
	3. Crackling (humid click)	—	—
	4. Cavernous (or gurgling)	—	—

This plan is a slight modification of that suggested by Dr. Walshe, as proposed by my colleague Dr. Cotton; but, however comprehensive and simple in appearance, it appears to me on practical grounds liable to objection.

It is difficult by any verbal representation to convey to one man a correct idea of the impressions made on the senses of another; and in adapting terms to describe impressions on the ear, it is undesirable to introduce those which are expressive of pathological conditions. The remarks of Skoda, that crackling is a dry sound, and indicates the presence of fluid, probably of a tenacious character, in some of the bronchial tubes, or in a cavity, may serve to illustrate the contradictory character of the language, to which designations involving speculative opinions are apt to lead. In the attempt now made to simplify the subject, I shall not include all the auscultatory sounds, but chiefly those of practical importance, which are most easily confounded, in consequence either of some supposed similarity in their character, or of the ambiguous terms by which they have been designated. Percussion sounds, modifications of sound derived from the voice, cardiac, venous and arterial murmurs are omitted; since they are far the most pathologic.

distinguished, and the terms by which they are designated are sufficiently expressive.

It is undesirable to give similarity of name and juxtaposition in arrangement, to sounds characteristic respectively, some of inflamed lungs, others of consumption, and I would venture to propose, as simple, distinct, and suited for clinical purposes, the following division into bubbles, clicking, crepitation, crackling, and vibration.

The first column exhibits the arrangement which I propose; the second, the corresponding terms in most frequent use; the third contains brief descriptions of the distinctive characteristics of each sound; the fourth notes the occurrence of the sound, whether chiefly in inspiration or expiration, or in both; the fifth shows the most common seat of each sound; and the sixth, the principal disease in which each sound is manifested.

TABLE II.

	Sounds.	Synonyms.	Character of sound.	Relation to		Common seat.	Accompanying disease.
				Inspiration.	Expiration.		
I.	Bubbling. a. Bubbling rhonchus b. Small bubbling rhonchus c. Gurgling	Mucous rhonchus. Subcrepitant rhonchus. Cavernous rhonchus.	Unequal irregular bubbles altered by cough. Few irregular bubbles.	— — — —	— — — —	Middle of both lungs. Base of both lungs. Summits.	Bronchitis. Capillary bronchitis. Excavation.
II.	Clicking.	Humid crepitation or humid crackling rhonchus.	2, 3, or 4 clicks.	— — — —	— — — —	Summits.	Softening tubercle.
III.	Crackling.	Dry crepitation or dry crackling rhonchus.	2, 3, or 4 dry sharp sounds.	— — — —	— — — —	Summits.	Unsoftened tubercle.
IV.	Crepitation.	Crepitant rhonchus.	Numerous minute, similar rapid puffs, like salt on fire, or rubbing lock of hair between fingers.	— — — —	— — — —	Base of one lung.	Pneumonia.
V.	Vibration. a. Sonorous rhonchus b. Sibilant rhonchus			— — — —	— — — —	General General	Bronchial asthma, etc.

I. BUBBLING SOUNDS are produced by air passing through secretion in the bronchial tubes, as peculiarly occurs in bronchitis; in those of moderate calibre constituting what has been usually designated mucous rhonchus. The smaller bubbling rhonchus produced in the capillary bronchi, commonly known as subcrepitant, should rather be termed sub-mucous, if, from respect to long usage, the somewhat questionable term "mucous" be retained. To these bubbling sounds the term rhonchus is appropriate; but I do not dignify with this title sounds probably produced externally to the cells, such as crackle and true crepitation, which are not proved to have any relation to the passage of air through secretion or vibrating tubes.

II. CLICKING consists of a series of sounds, few in number, exactly corresponding to the term, audible in some degree during expiration as well as inspiration, and probably never existing except when softened tubercle is present.

III. CRACKLING—a term which itself defines the sound—consists of a few, (not more than three or four,) crackles limited to the period of inspiration, seeming to arise at a distance from the ear, probably produced externally to the cells, and characteristic of the first stage of phthisis, although not invariably present under such circumstances.

IV. CREPITATION consists of more numerous and finer sounds than crackling. It is also confined to the period of inspiration, and is probably due to viscid secretion in the cell-walls, occasioning difficulty in their expansion. It is peculiar to pneumonia.

V. VIBRATIONS. Of sonorous, grave or cooing, and sibilant, shrill or whistling rhonchus; sounds resulting mainly from vibration, and indicating flattening or narrowing of tubes, such as is common in chronic bronchitis, it may be sufficient to remark that, when occurring interruptedly, these rhonchi may be occasioned by vibrations of air produced by pellets of mucus, as is sometimes observed in pertussis; but that in proportion to the continuousness of these sounds, there is reason to suspect turgescence or thickening of the membrane, or effusion in the submucous tissue.

A few incidental remarks may here be expedient, in order to explain a little more particularly the modifications which are suggested in this communication.

The term subcrepitant rhonchus has been so long and extensively employed, that the attempt to displace it may seem a bold and doubtful experiment; but I scarcely know a medical expression which has tended to more danger in practice. The term conveys to the mind the idea of a sound analogous to that usually designated crepitant rhonchus (but which I propose to call crepitation); and has in consequence led to injurious depletion. If asked to specify the greatest abuse of auscultation with which I am conversant, I should instance the leeching and antimonializing of children, in certain pectoral affections, of which the subcrepitant rhonchus is a prominent symptom. Under the cover of a pedantic numerism, the cure of pneumonia without depletion has, on the continent especially, been assumed to be common, because this so-called subcrepitant rhonchus, although really differing in character of sound, as well as in cause, has been mistaken for the rhonchus characteristic of pneumonia. A reference to the table (No. 2) will show the marked difference between these sounds.

As respects diagnosis and treatment I cannot but think that great importance may be advantageously attached to the co-existence of certain sounds with expiration as well as inspiration, with certain qualifications, particularly in reference to vibratory rhonchi; the presence of a morbid sound during expiration affording evidence of the presence of secretion within the cells or tubes. This view is supported by the concurrence of clicking, from softened tubercle, with both respiratory actions, as contrasted with the inspiratory crackle of the first stage of phthisis. The same peculiarity distinguishes the small bubbling (submucous rhonchus) from true crepitation (crepitant rhonchus), which resembles the noise produced by rubbing a lock of hair between the fingers, and conveys to the mind an idea (probably in harmony with the fact) of the abrupt forcing open of cells rendered less yielding by glutinous deposition in their walls.

If the cause commonly assigned for "crepitant rhonchus"—namely, air passing through secretion—were correct, the air in repassing should produce a rhonchus during expiration also. The presence of viscid secretion within the pulmonary cells in pneumonia may be acknowledged, without conceding that this secretion is concerned in the production of crepitation; indeed, its tenacity may be a reason why bubbles are not produced, the calibre of the capillary tubes to a certain extent remaining free. When, in the resolution of pneumonia, the secretion becomes less viscid, and occasionally more copious, the rhonchus changes in character, and the sound which has been designated the *redux* crepitant rhonchus, having more of a bubbling character, and more or less audible during expiration, is produced. The sound sometimes termed continuous subcrepitant rhonchus, existing only during inspiration, and accompanying pulmonary congestion such as attends some forms of fever, I should regard as a subcrepitation, not a rhonchus.

As respects the treatment of inflammatory affections of the lungs, in proportion as sounds are confined to inspiration, they afford reason for depletion; in proportion as the rhonchi become bubbling, they indicate secretion, and suggest a discontinuance of antiphlogistic treatment.

The advantage of introducing terms so diverse as is suggested in the present plan is obvious. If we speak of crackle, the first stage of phthisis is indicated; if of clicking, the stage of softening; if of crepitation, pneumonia is known to be present; if of bubbling or small bubbling rhonchus, secretion more or less copious is known to be present in the different orders of bronchial tubes.

Some authors, otherwise instructive, have complicated the subject of auscultation by looseness of expression, as well as by over refinement. Dr. Stokes, for example, in a work generally admirable for breadth of view and clearness of style, has sanctioned the use of that ambiguous term "muco-crepitant rhonchus"; regarding which it has been well observed, that if twelve physicians were asked the meaning, it is doubtful whether two would agree.

It is a sufficient proof of the vague manner in which auscultatory terms are employed, that when an author uses the word crepitation, we are often at a loss to determine whether he intends dry crepitation (crackle), moist crepitation (clicking), or subcrepitant rhonchus (small bubbling rhonchus), or the true crepitation (crepitant rhonchus) of pneumonia.

The distinctions attempted in this communication may be open to incidental objections; and doubtless the phenomena observed in practice are not likely exactly to correspond with systematic arrangements; but the beginner requires broad distinctions, and his own studious care will familiarise him with the requisite modifications. It should be remembered that the loudest sounds are not the most important. On the contrary, catarrhal affections of the larger tubes may seem to the novice more alarming than the fine crepitation of pneumonia, or the delicate crackle or clicking of phthisis. Skoda has expressed an opinion that dry crepitation (crackle), and moist crepitation (clicking), are bronchial sounds, and have no necessary relation to consumption. I cannot concur in this conclusion, although aware that varieties of subcrepitation may be mistaken for them, if we overlook the modifications produced in bronchial sounds by deep inspiration or cough. If a doubtful sound is removed by cough, or superseded by vibration sounds on deep inspiration, we may, with little exception, conclude that it is not crackle or clicking.

Let me venture to urge the desirableness of avoiding the mongrel combinations of different languages, too common in medical descriptions, and of adhering, whenever practicable, to our own mother tongue. The avoidance, as far as possible, of foreign expressions, is important to simplicity, to accuracy, and one is almost tempted to add, to patriotism. And although, in this particular department of physical science, the use of French words has a special palliation, it is yet better to sacrifice this consideration; since, whenever our own language is deficient in descriptive terms, Greek words, or Latin words of Greek derivation, have the superiority in expressiveness, and in harmony with our own. Of this

truth, the word "terminus", for the extremity of a railway line, may furnish an example. For the purpose of designating certain unnatural sounds not easily expressed by any of our English words, the word "rhonchus" is perhaps the most appropriate, from its compass and expressiveness of meaning; but there are advantages in restricting its application to sounds produced by air permeating tubes or cells, modified by the condition of those tubes or cells, or of the fluid through which it passes. The original word "rhonchus" was occasionally employed to represent the sound of air disturbed in its course; but not unfrequently to signify the murmur of waves against particular obstacles. It was especially applied to the noise of deep waters striking against precipitous rocks. Those readers of this Journal who retain the youthful freshness of their classical literature, may recollect other instances. I will only quote an example of the use of the kindred verb in the beautiful description which Homer gives of the waves breaking against the rocks of Scylla:—

Ἐρθεν μὲν γὰρ πέτραι ἐνπρόθεες, πρὸς δ' ὕδατος
Κῦμα μέγα βοῶντι κνανόωντος Ἀμφιπύργου

It may be objected that the introduction of new terms will tend to increase the perplexity we desire to avoid; but this difficulty may be to a great extent obviated, if, in using words not generally adopted, the best understood of synonymous words be placed in parentheses; for example, crepitation (crepitant rhonchus), bubbling rhonchus (mucous rhonchus).

In conclusion, it should be observed that the most accurate description of sounds, and the greatest aptitude in their detection, must never be considered sufficient without a careful investigation of collateral symptoms. A habit of expecting conclusive evidence from unassisted auscultatory signs has frequently entailed disappointment, and induced unreasonable disparagement of this branch of the medical art. A change of sound doubtless proves a change of condition; but as several pathological conditions may sometimes induce a similar sound, other indications must be sought, in order to determine which of these conditions is present. Notwithstanding the definiteness of information regarding local affections, which auscultation may often supply, no prudent practitioner would determine his treatment without taking into account such circumstances as the degree of rapidity or labour in respiration, the character of the expectoration, and the amount of constitutional disturbance. The inadequacy of any single indication as a guide applies, however, still more to symptoms arising from sympathies than to those depending on acoustic principles. There is in some minds a "barrenness of faith" leading them to distrust the details which conduce to general truth; and it is doubtless easy to be unnecessarily minute in distinctions of sound, but the misuse of auscultation arises less frequently from undue refinement than from a want of correct appreciation of the distinctions most practically important. Disproportion is the great cause of erroneous opinion, no less than of monstrous forms. It is better to begin with doubts and end with certainty, than to begin with confidence and end with distrust; and I cannot question that whilst auscultation is studied with the caution and ingenuousness of true philosophy, it will never lose ground in the estimation of the profession.

3, Bedford Square, April 12th, 1853.

ON THE OCCURRENCE OF HERNIA BRONCHALIS DURING LABOUR.

By HUGH ROBERT RUMP, Esq.

THE following observations on hernia bronchalis, as it occurs during labour, I have been induced to offer, from the silence of all obstetric authors on the subject; at least as far as I am enabled to judge. Burns is the only writer who alludes distinctly to the neck as a region connected with the process of parturition in a pathological sense, and then only as regards bronchocele. In the treatment

* *Odyssey*, xii, 55-56.

chapter of the tenth edition of his *Principles of Midwifery*, he writes—"Swelling of the thyroid gland takes place so much more frequently after parturition than under other circumstances, that it may with propriety be mentioned here. It appears within a few days of delivery, and is often attributed to exposure to cold. In other cases, the woman feels as if something had given way about the throat. It may remain long in an indolent and stationary state, being productive either of no material inconvenience, or only of a slight difficulty of swallowing. In other instances, it augments in size, and becomes dangerous, from its pressure on neighbouring parts; or it forms a large abscess, and bursts."

It is somewhat singular that two, if not all, the cases about to be related had been mistaken for bronchocele, and treated accordingly.

Hernia bronchialis, goître vesiculaire, goître arien, hernia gutturalis, and bronchocele vera, are synonymes for a peculiar protrusion of the mucous membrane lining the air passages, either through the crico-thyroid membrane, or between two of the cartilaginous rings of the trachea; forming externally, in front or on either side of the throat, a soft tumour, not tender to the touch, and without discoloration of the integuments. The first description of this very remarkable tumour was given by Larrey in his *Clinique Chirurgicale*, tome xi, p. 81. The subjects of this disease who came under his observation during the war in Egypt, were some French soldiers and Mahommedan priests; persons who had been in the constant habit of calling at the highest pitch of the voice. This continued vocal effort he regards as the sole cause of the disease. He says—"Notwithstanding the statement of the authors who have written upon goître, we have accurately observed and recognised that which has been designated under the name of bronchocele, but which might be termed, with greater propriety, pneumo-guttural hernia. It consists of one or more air tumours, which form in front of the throat, and principally by the sides of the larynx. These tumours, which sometimes acquire a considerable size, may be attributed to the arrangement of the parts, and to the more or less violent efforts occasioned by the cries or songs of the individual. The air which has served for the purpose of inspiration, being afterwards, by the effort of expiration, driven outwards with all the modifications necessary to impart to the cries, or the voice, the desired intonations, gradually produces these tumours."

The diseases or affections likely to be confounded with hernia bronchialis, are—1, bronchocele: 2, cystic disease of the thyroid gland; 3, a cyst situated beneath the deep cervical fascia, and in proximity with the carotid sheath. It may, however, be readily distinguished from these diseases, and its true nature accurately ascertained, by observing—1, that it greatly diminishes in size, or entirely disappears, upon the application of gradual and uniform pressure; 2, that on a deep inspiration being made, the tumour ceases to be prominent, the air being withdrawn from its interior, its walls collapse, and scarcely any swelling is perceptible; 3, that during a strong expiration, the nostrils and the lips being at the time compressed with the fingers, the opposite condition ensues, the air rushes into the interior of the hernia, and it becomes tense and greatly distended. With aneurism it could scarcely be confounded.

From the facts which I have been enabled to collect, it appears that hernia bronchialis occurs during the second stage of severe and protracted labour, in which uterine action is very powerful, and where considerable resistance is offered to the passage of the head, either by a rigid and unyielding perineum, or by contraction of the pelvic outlet. The same circumstances which favour laceration of the perineum, I apprehend may be productive of hernia bronchialis. During the violent straining of the last pains of labour, the diaphragm is fixed, the abdominal muscles powerfully contracted, the glottis closed, and respiration for a time suspended; the cavity of the thorax becomes diminished, and the air contained within the lungs is forced upwards against the inferior surface of the glottis,

carrying with it and elevating the larynx to a certain extent, thereby producing a *certain amount* of elongation of the trachea, separation of its rings, and consequent attenuation of its tissues; the same force will render the crico-thyroid membrane tense, and place it in the most favourable condition for separation of its fibres. The accuracy of the foregoing remarks, as regards the effects of straining upon the larynx and trachea, may be tested by personal experiment.

In ordinary labour, the force of the column of air upon the sides of the trachea and larynx is gradual and moderate; if it be excessive, hernia bronchialis may result. During puerperal convulsion, the closure of the glottis is sudden, the pressure is immediate and fearful, and the tissues unable to sustain it; rupture, and then emphysema, ensue. Of the latter accident, the following case is an example.

CASE. Mrs. S., aged 26, at the full period of pregnancy with her first child, was seized, early on the morning of the 19th January, 1849, with violent convulsions, and perfect insensibility. I was summoned immediately, and found her in a comatose condition, lying on the back, with the arms and legs extended, and the head thrown backwards. The face was slightly flushed, and bedewed with perspiration; the pupils were contracted; and the pulse in the radial and temporal arteries was full and bounding. The relatives of the patient stated that she retired to bed on the previous evening in her usual health; but that about a week previous, she had suffered from extreme giddiness, and partial loss of speech for a few hours. These symptoms were attributed, at the time, to constipation; and a free action of the bowels having been procured, they entirely subsided. It was evident that no time was to be lost. A vaginal examination being made, the os uteri was found undilated, and the vertex presenting. The patient was propped up with pillows, and between thirty and forty ounces of blood taken from the arm, in a full stream. The hair was cut off closely, and linen cloths, dipped in cold water, were applied to the head; sinapisms were placed on each calf; and two drops of croton-oil, with ten grains of calomel, mixed with a little butter, were put on the back of the tongue. About an hour after the venesection, convulsions recurred, and lasted a few minutes, but were less severe than the first. During the succeeding three hours, the patient was convulsed every twelve or fifteen minutes; the fit now being evidently connected with uterine action, and preceded by restlessness and moaning. On examination, the os uteri was found dilated to the size of a half-crown, thick or cushion-like, and well lubricated with mucus. The membranes were unruptured. A strong terebinthinate enema was now administered. A very short period had elapsed after the administration of the enema, when a convulsion of the most alarming character occurred. The patient had been lying tolerably still, when suddenly slightly raising herself from the bed, she uttered a cry, and fell backwards frightfully convulsed. The head was jerked violently to the right side, froth issued from the mouth, the teeth were ground together with the greatest violence, the extremities were extended and rigid, and the head and neck became tinged with blood, and almost purple. She appeared, in fact, upon the point of suffocating. The seizure, however, gradually subsided, and it was noticed that the neck had become much enlarged, and that the swelling was extending over the face. By making pressure with the finger upon the neck, crepitation in the areolar tissue was distinctly felt; and it was manifest that emphysema, from rupture of the air-passages during the paroxysm, had taken place. The pains were now strong, and recurring at very short intervals, but were unaccompanied by convulsion. The patient still remained in the most profound insensibility. The emphysema progressively increased, air having universally permeated the areolar tissue, and the patient's appearance becoming most singular, resembling that of a case of general anasarca from obstructive disease of the right side of the heart. Delivery was effected shortly afterwards; but consciousness did not return until after the lapse of nearly three days. The extravasated air be-

came gradually absorbed; and, after a series of relapses, the patient finally convalesced.

Having thus attempted to explain the causes, or mode of production, of emphysema and hernia bronchialis during labour, and having adduced the preceding case in support of my views on the subject, I shall now proceed to give the histories of three cases of hernia bronchialis, two occurring in my own practice, the third in that of my friend Mr. Parry, of Docking, to whose kindness I am indebted for the report.

CASE I. Mary Stone, aged 36, the wife of an agricultural labourer, a woman of highly strumous aspect, consulted me for an enlargement of the submaxillary glands. Upon exposing her neck, my attention was arrested by a very singular tumour on the right side, in the space between the sterno-mastoid and the larynx. It was of an ovoid shape, and of the size of a turkey's egg, perfectly smooth, painless, and elastic to the touch. After considerable manipulation, I was inclined to believe it a cystic growth, and was carefully regarding it, when the patient, probably fatigued by the long examination, drew a deep inspiration, and, to my astonishment, the tumour decreased to half its former size. I then requested her to compress firmly the lips and nostrils with her fingers, and to make a strong inspiratory effort. The result was, that the tumour became scarcely visible. The lungs having been thoroughly inflated by a deep inspiration, the nose and lips were once more compressed, and a forcible expiratory effort being made, the tumour became greatly distended, remarkably tense, and projected considerably from the neck. It was now evident that it was a sac or cavity communicating with either the larynx or trachea; in fact, the hernia bronchialis of Larrey.

In reply to my interrogations, she stated that she had always been very delicate and sickly, and had suffered, whilst a girl, from suppurating lymphatic glands. She married at the age of twenty-one, and had had eight children. In her third labour, which was unusually severe and protracted, a distinct snap took place, and the swelling on the right side of the throat immediately presented itself. She said that she expressed at the time her conviction "that something had burst in her throat". She considered that the tumour increased in size with each succeeding labour.

The above case at the time I considered unique, and showed it to several of my medical friends, who coincided with me as to its interest and rarity.

The woman died very suddenly on the 7th April, 1848, from some obscure cause; and as the coroner's jury returned a verdict without having heard medical evidence, the husband resolutely refused a *post mortem* examination.

CASE II. Mary Tuddenham, aged 28, the wife of an agricultural labourer, residing at South Creak, enjoyed excellent health until she attained her twenty-second year, when she married, and since marriage had never been robust or well. She had had four children. After her first confinement, she perceived a swelling on the right side of the neck; but as it occasioned but little inconvenience, she did not seek medical advice. The tumour presented very much the appearance of unilateral goitre, for which it might be readily mistaken, as there was considerable thickening about the sac; but upon careful examination, hernia bronchialis was easily recognized. The woman was the subject of frequent distressing headaches, lasting many days together; indeed, she was very seldom free from headache. My friends Dr. Rudge and Mr. Parry examined the case, and concurred with me as to its nature and probable cause. (See Figure.)

CASE III. Mrs. Quantrill, aged 35, the wife of a labourer, consulted Mr. Parry for an enlargement of her throat. She had always enjoyed excellent health, and had never suffered from any particular disease. She married at twenty-one; and during her first confinement, which was very severe, she was desired by the midwife in attendance, during an expulsive pain, to "hold her breath, and bear down", when she felt something give way in her throat, but did not im-

CASE II.

mediately discover the swelling. She had particularly observed that the tumour had increased in size both during and after her subsequent confinements.

Her throat presented all the appearances of goitre, for which the swelling had been mistaken several times, and had consequently had iodine ointment applied to it. Upon requesting the patient to swallow, the tumour rose and fell with the larynx and trachea, thus simulating bronchocele: but upon closing the mouth and nose, and directing her to make a deep inspiration, the swelling almost disappeared, but immediately resumed its former condition upon expiration.

Since I was furnished with the history of this case, Mr. Parry has attended the subject of it in labour, and informs me that a remarkable augmentation in the size of the tumour took place during the expulsive pains.

Loss of voice, partial or complete, and constant headache, were noticed by Larrey, as prominent symptoms in all the cases which came under his observation; the latter symptom he attributes to "pressure exercised by these tumours upon the superficial vessels of the neck, determining a stasis of blood in the sinuses of the dura mater".

In only one of the preceding cases was headache complained of. There was no diminution of vocal power in any of the patients. The cry which generally, or at least frequently, occurs at the termination of the second stage of labour, or whilst the head is passing through the os externum, has been said by some obstetric writers to be conservative. By the glottis being opened, the air rushes from the chest, the diaphragm ascends, and the pressure of the foetal head, which had threatened the integrity of the perinæum, becomes moderated. During the closure of the glottis, short in duration though it be, may not the larynx and trachea be as equally exposed to rupture as the perinæum?

As to the treatment of this singular affection, little, I apprehend, can be said. The neck is so circumstanced in an anatomical point of view as to preclude the possibility of compression being efficiently applied. Larrey states:—"The most desirable indications in this description of disease are—first, to unload the vessels of the head, by the abstraction of blood from the jugular vein; secondly, to excise, in combination with repercussive sedatives, a great compression on the tumour."

Of these remedial measures, I have no experience. In bringing forward the foregoing cases, my object has been rather to draw attention to the diagnosis of this singular affection, than to offer or advocate any novel mode of treatment.

Wells, Norfolk, April 1853.

CASE OF ABSCESS OF THE LIVER: SPONTANEOUS EVACUATION: CURE.

By FREDERICK MASON, Esq.

CASE. Mrs. —, a laundress, aged 58, had had slight pains in the epigastrium and bowels for some weeks. She had hernia on both sides for many years, easily reducible; and she had suffered very little uneasiness from this cause. On December 20th, 1852, she did an unusually heavy day's work, continuing at it until one o'clock the following morning. On the afternoon of this day (21st), she was seized suddenly with violent pain in the left side, a little below the margin of the ribs. I saw her about 10 o'clock, P.M. She was sitting on the edge of the bed, complaining of intense pain in the left side of the umbilical region, increased on pressure, and preventing her from lying down. The skin was cold; the tongue moist; the pulse 74, and weak. She had no vomiting. The bowels had acted once on the 20th, but not on this day. The hernia on the left side was not protruded; that on the right was to some extent, but was very easily reduced. I directed her to have the bowels well and constantly fomented with flannels wrung out of hot water, and to take four grains of calomel and ten of Dover's powder directly; to be followed by an effervescing mixture of citrate of potash every four hours, and a dose of castor oil early in the morning.

December 22nd. The pain in the left side was relieved, but was more severe in the right hypochondrium, and more especially so in the epigastrium, passing through to the back and to the left shoulder. The bowels had acted twice. I prescribed one grain of calomel and four grains of Dover's powder every six hours; and ordered the mixture and fomentations to be continued.

December 23rd. The pain was not so violent, though still severe. I directed six leeches to be applied to the epigastrium, and ten minims of tincture of opium to be added to each dose of the mixture.

December 24th. The gums being slightly affected by the calomel, it was now discontinued.

December 25th. The pain had increased, and a circular swelling, about two inches in diameter and a quarter of an inch in height, had appeared in the epigastrium. The heart-sounds were very distinct and clear beneath the swelling; and there was an impulse communicated to it, but no *bruit* of any description. She complained of severe throbbing pain in the swelling. I prescribed two-thirds of a grain of solid opium every six hours. In the evening of this day, she had frequent and violent attacks of shivering, followed by cold sweats. The pain not having abated, she was ordered to continue the opium, and to apply six more leeches.

During the following week she continued much in the same state. She had occasional attacks of shivering; generally lay on her right side; and complained of numbness in the left side, especially in the arm and leg, when she turned on to her back. Morphia was substituted for opium at bed-time; but it failed to procure sleep.

January 5th, 1853. The swelling was increased in size, more tense and elastic to the feel; but I could not detect fluctuation.

January 6th. She appeared better. She said that, on the preceding evening, she felt a sensation of something bursting "with a pop" beneath the swelling; and that soon afterwards a profuse diarrhoea began. The evacuations were so offensive, that they were obliged to be thrown away immediately: they were said to be of the colour and appear-

ance of barm. The swelling was gone, and also the arterial impulse. She had no vomiting.

January 7th. She was better, and had less pain. The bowels were not so much relaxed. The motions were feculent. The tongue was covered with a moist slimy-looking fur. The pulse was weak and quiet.

January 8th. The tongue was cleaner. The appetite had improved. She complained of a very foetid-smelling and nauseous froth frequently rising in the mouth. Pulse 72.

From this time she gradually improved. Slight tenderness on pressure along the margin of the liver remained for a few days, but this soon quite disappeared. She was able to sleep well without morphia.

January 17th. She sat up for three hours. There had been no return of pain.

January 28th. I found her down stairs, doing a little light work; and I was now able to discontinue my attendance.

I have made inquiries for her lately, and find that she continues well.

5, Cleveland Place East, Bath, April 1853.

LIGATURE OF THE EXTERNAL ILIAC ARTERY FOR A WOUND.

By JAMES OGDEN, M.D.

DURING my practice as a surgeon in Rochdale, the following case occurred to me in 1825. Although so many years have elapsed since the operation, I have not seen another case recorded of tying the external iliac artery for a wound; nor have I been able to elicit from the experience of my professional friends, or from any other source, any account of a similar case. Having been often solicited to communicate the circumstances of the case, I have done so from the notes of my case-book, as an unique contribution from the records of an extensive practice of many years.

CASE. Jeremiah Crossley, aged 26 years, a stout and active young man, having provoked an irritable Irishman, a vendor of small wares, whilst stepping into a public-house, was attacked by him on coming out, and stabbed with a long sharp penknife in the right iliac fossa, about an inch above Poupart's ligament. A most frightful hæmorrhage ensued; and he was instantly dragged across the street into my surgery, in a state of syncope, apparently dead, and his clothes saturated with blood; on their removal, blood was found flowing *per saltum* from the wound.

With the assistance of my apprentice, Mr. Preston, now of Prestwich, and the late Mr. Buckley, I immediately passed a director between the peritoneum and the fascia transversalis, cutting this fascia, and the internal and external oblique muscles, so far as to allow me to introduce my finger as a guide for the better protection of the peritoneum. I carried the incision upwards for about three inches, in the direction of the anterior superior spinous process, about an inch and a quarter internal to it. The coagulum which presented itself was scooped out; and, carefully drawing aside the peritoneum and gradually separating it from its cellular attachments to the parts beneath, I was enabled to raise the artery upon the point of my finger, when the wounds in the sheath and artery were perceived. Compression with the finger retarded the hæmorrhage. The wound in the fascia was somewhat enlarged, so as to enable me to apply a double ligature, taking care at the same time not to denude the vessel of its *vasa vasorum* any more than could possibly be avoided, and carefully separating the vein from the artery. On examining the state of the parts more minutely, I found that a nerve was included; this was excluded by passing a second needle, armed as before, and withdrawing the first. The artery was then secured firmly, above and below the wound; one end of each ligature was cut off close to the vessel, and the

wound in the abdomen secured by sutures, etc. The necessary means were taken to restore animation and warmth to the extremities; and, in the space of two hours, we had the gratification to find pulsation at the wrist, and, in half an hour afterwards, consciousness. The patient was placed in bed at the inn, with the limb slightly bent, and supported by pillows at the knee. A draught was given, composed of spirits of ammonia, compound tincture of cardamoms, and Battley's sedative solution of opium. Warm applications were applied to the feet, etc.

November 14th, 6 P.M. Six hours after the operation, he became somewhat restless. The foot and leg were cold, and no pulsation could be felt in the femoral, popliteal, or anterior tibial arteries. The draught was repeated, and warmth applied to the leg and foot. The wound was tolerably easy. Considerable reaction had taken place. The pulse was 110, small, and compressible.

November 15th, 6 A.M. He had been composed during the night. There was free perspiration. Pulse 96, much firmer.

At 8 P.M., he was slightly feverish; the pulse was full, and more bounding; the bowels had not been moved since the operation, at which time they were evacuated involuntarily. He was ordered to take immediately a grain of opium with three grains of calomel.

November 16th, 7 A.M. He slept several hours during the night. This morning he was feverish, with slight head-ache. Pulse 100. Half-an-ounce of castor-oil in mint-water was given. There was no pain or tenderness in the abdomen; the wound was not painful, but slightly tender when pressed upon; the leg and foot were cold.

At 7 P.M., the bowels had been freely moved; the pulse was 92; he was free from head-ache, and perspired copiously. The leg and foot were cold, and of a dingy colour.

November 17th, 8 A.M. He passed a good night. The pulse was 90, with occasional *intermissions*. The abdomen was soft, and free from tenderness on pressure; the leg and foot were cold as marble, and mottled in places. There was no return of pulsation in any of the tangible arteries of the leg.

At 7 P.M., he was much the same as in the morning. A draught was given, with twenty drops of Battley's sedative solution, and an ounce of liquor ammoniæ acetatis.

November 18th, 8 A.M. The adhesive plasters were moist with a slight sanious discharge from the wound.

At 8 P.M., he remained much the same.

November 19th, 7 A.M. The leg and foot were still cold. He appeared more anxious in his looks. I partially dressed the wound, which looked healthy, and was slightly adherent in parts. The pulse was 100, and feeble. The draught was repeated at night.

November 20th, 7 A.M. He was free from pain. Pulse 92. There were slight typhoid appearances, and occasional singultus. The leg and foot were perfectly cold, dark, mottled, and somewhat shrivelled.

At 8 P.M., he was restless. The pulse was too irregular to be counted satisfactorily, but was supposed to be above 100, including intermissions. The draught was repeated, with a musk and ammonia bolus, formed with opiate confection.

November 21st, 7 A.M. He had some sleep during the night. The skin was moist and clammy. The leg and foot were almost black, more shrivelled, cold, and in a state of gangrene. The hiccup continued. There was slight discharge from the wound, but not offensive.

At 9 P.M., the symptoms were much the same. He was occasionally incoherent, and said, when asked, that he had not the least pain. The draught and bolus were repeated.

November 22nd, 4 A.M. I was called in haste, on account of hæmorrhage, and found him in *articulo mortis*, and deluged with blood. He died in a few minutes.

EXAMINATION OF THE BODY. We found that the artery on the cardiac side of the ligature had sloughed, having partaken of the mortification in the extremity and contiguous parts.

REMARKS. This case was pronounced, by the verdict of the jury at the coroner's inquest, to be one of wilful murder; but this verdict was ignored by the grand jury at Lancaster, and the case was tried before the late Judge Bailey as one of manslaughter. The prisoner was committed for the term of two years.

On the third day after the operation, I was convinced that the case would terminate fatally, as no warmth or circulation could be established; proving to me that the anastomoses would not be sufficient for the supply of blood to the extremities, owing to the circulation having been too suddenly cut off to give the gluteal and other collateral branches time to become sufficiently dilated, to enable them to carry on the circulation in the limb below.

Arndwick Villa, Manchester, April 1853.

PERISCOPIC REVIEW.

EPIDEMIOLOGY, HYGIENICS, AND STATISTICS.

STATISTICS OF THE DEAF AND DUMB IN IRELAND.

THE *Journal of the Statistical Society*, published last month (March), has an interesting article, bearing the title given above, by Mr. W. R. WILDE, Assistant-Commissioner for the Census in 1851. This census was made the medium of the inquiry, with the permission of the Lord Lieutenant, and at the request of the local secretaries of the Society. The return also presents at one view, not only the amount and distribution of disease, but also the maladies to which the inhabitants of Ireland are most exposed at a certain period of the year. This, we believe, is the first attempt yet made to collect and tabulate the diseases presented on a single day in even a limited portion of any country. We earnestly solicit the attention of the profession to the very important medium of observation thus opened to the study of endemic disease. The general return of the diseased is divided into permanent and temporary; and foremost among the former stands *deaf-mutism*, a subject highly interesting, both in its physiological and social bearings.

The exact number of the deaf and dumb population cannot be precisely ascertained, from the difficulty of determining mutism under two years of age. It appears probable that the estimate for Ireland would be about one deaf-mute in 1,500 inhabitants. For all Ireland, 4,485 deaf-mutes were returned, or 1 in 1401 inhabitants. Taking the most authentic information for our guide, this approaches very nearly the proportion of the whole of Europe, which is one in 1,593. "The duchies of Luxembourg and Wurtemberg, and the kingdoms of Tuscany, Bavaria, Belgium, and Holland, possess the fewest, while Sardinia, Norway, and parts of Switzerland, exhibit the greatest number of deaf-mutes in proportion to their populations; the average of the former countries being one in 2,209, and of the latter, one in 641.9. In some of the Swiss cantons, the proportion of the deaf and dumb to the population is as high as one in 206; and in those localities it is generally combined with cretinism and idiocy. In a country like Ireland, completely insulated, limited in extent, and possessing great sameness of surface, one would not expect that the proportion should alter very much in the different provinces and counties; still we find the following variation:—in Leinster, one in 1,794; Connaught, one in 1,689; Ulster, one in 1,487; and in Munster, one in 1,409. Deaf-dumbness, arising from all causes, prevails most in the rural, and least in the civic portions, or those towns whose inhabitants amount to 2,000 and upwards, exclusive of workhouses. Thus there are fewer cases in proportion to the population to be found in the towns of Drogheda, Carrickfergus, Galway, and Belfast, and the cities of Cork and Dublin, the average for these places being one in 2,384. Generally speaking, the flat campaign counties, such as Roscommon, Westmeath, Dublin, Meath, and Kildare, present the fewest cases; the average in these being one in 1,950; while Mayo, Limerick, Donegal, Waterford, and Wicklow, and also Tipperary, Tyrone, and Fermanagh, the five first lying chiefly on the coast, and the majority presenting mountain ranges, have a greater number of deaf and dumb, in proportion to their population, than the remaining counties, their average being one in 1,338; and in Wicklow the proportion is as high as one in 1,000. Leitrim, Clare, Down, and Antrim, are also high.

"Of the total 4,485 mutes, 4,151 were deaf and dumb,—2,349 males and 1,802 females; and 334 were dumb but not deaf. Among the former class, 3,325 were born so, and 400 became so after birth by accident or disease. In 267 instances, the precise cause was uncertain or unknown; and in 159 cases, the persons were at the same time paralytic, idiotic, or both. Among the latter class—the dumb, not deaf—181 were dumb only without defect, 45 were paralysed, 115 idiotic, and 43 both paralytic and idiotic.

"The sexes of the deaf and dumb from all causes are as 100 males to 76.61 females; such being in accordance with the usual law which appears to regulate the sexes in this class. Among the congenital cases, the proportion is 100 males to 74.62 females; and in the acquired, it is 100 to 91.37—showing in the former an excess of males over and above the general proportion of that sex. It must, however, be remarked, that according to the present census, there is an undue proportion of females above males in Ireland.

"Among the sixteen tables inserted in the report, there are two which show, by ages and sexes, the occupations of the deaf mutes themselves, as well as the employment of their parents. The former exhibited the great variety and extent of arts, trades, and handicrafts, upon which the deaf and dumb are capable of being employed; and the latter showed that the great bulk of the mutes in Ireland are derived from the agricultural and labouring classes.

"Among the subjects discussed in this report, is that of marriage and its results, as regards the offspring of deaf mutes. In 77 instances, one parent was deaf and dumb, and in 5 instances both parents; from these marriages but two mute children resulted, one to each class. It is remarkable, that while mutism is often manifest in several members of a family derived from a common stock, the defect is seldom transmitted direct from parents to children; thus, according to the returns of the Hartford Institution, in the United States, we learn that out of ninety-one instances where both parents were deaf and dumb, there were only four cases in which the children were similarly affected.

"Several tables have been constructed, with a view of showing the number of mute children born to each family, and the proportion of the sexes, where there was more than one mute, the position in the family, whether first, second, or third child—in 2,962 instances—the result of hereditary predisposition, and the consanguinity of parents, as well as the causes of acquired deaf-dumbness, and the ages at which the diseases or accidents producing such occurred. The state of education, and the number, locality, and date of erection of the several institutions for the instruction of the deaf and dumb in Ireland, as well as the mortality and causes of death, and even the particular races, whether Irish, English, or Scotch, to which the deaf and dumb belonged, were likewise described, all showing with what minuteness this interesting inquiry had been sifted.

"The following are some of the results obtained:—2,512 families had one mute child; 287, two mutes; 127, three mutes; 32, four mutes; 8, five mutes; in 3 instances there were six; in 1 seven; and in 1, eight mute children, born of the same family of the same parents. Fourteen instances occurred of twins, in which one or both were mute; and families of six and seven had more frequently a mute child born among them than families of any other number. In every instance the male sex largely predominated, except in cases where the eighth child was deaf and dumb, and in these the sexes were about equal. In 154 instances, the parents were related; and out of 281 cases, in which the influence of hereditary predisposition in the production of congenital mutism was traced, it was shown that in 149 instances the taint descended through the father's side, and in 132 through the mother's. The family history had been traced back in several instances to the grandparents, and in a large number to the cousins and collateral branches.

"Six cases were recorded of persons deaf, dumb, and, blind; and a great number of instances were related of rare and remarkable cases, showing peculiar combinations of deaf-dumbness, with other congenital or acquired defects."

The report is highly interesting, as giving the history of the instruction of the deaf and dumb from the earliest period to the present time. The first educational establishment for the deaf and dumb in Great Britain was that established by Thomas Braidwood, in 1760, which is spoken of in terms of commendation by Dr. Johnson, in his *Tour to the Hebrides*.

"In concluding the subject of the education of the deaf and dumb, the commissioners have suggested the propriety of ingrafting upon the system of national education some institutions for the instruction of this class of the community.

"The popular terms for deaf-dumbness are: deaf and dumb—dummy—the silent people—mutes; and in the Irish, *Bodhar agus Balbh*—deaf and dumb. Some interesting instances of persons so circumstanced have been related in the Irish metrical romances and bardic histories. The Irish medical manuscripts of the sixteenth and eighteenth centuries abound with notices of diseases of the ear and deafness.

"The subject of race, in so far as it affects the deaf and dumb, is another subject of great interest. It appears that out of 1,671 so afflicted, 1,198 were Irish, 352 English, and 121 Scotch.

"The last subject which falls to be considered is the mortality of the deaf and dumb. In 291 instances the cause of death was recorded; and we learn that 72 persons died of zymotic or epidemic diseases, of which fever, dysentery, and small pox, were the most fatal; and 135 died of sporadic diseases. Consumption was the cause of death in 77 instances; it is not only the most frequent cause of death in this class, showing a proportion of one to 2.81 of the entire number of specified causes; but the fact thus related confirms the opinion, that as deaf-mutism itself is frequently a variety of struma, so are the persons afflicted therewith more particularly predisposed to diseases of a scrofulous character in after life. Ten met with violent or sudden deaths: rather a large proportion, but one naturally resulting from the deprivation under which this afflicted class all suffer."

To this report is subjoined the substance of a letter from Dr. Peet, the Superintendent of the Institution for the Deaf and Dumb at New York, containing the unpublished results of the American inquiry into the state of the deaf and dumb, in common with the blind, insane, and idiotic. From it we learn that there were 9,422 white mutes in a population of 19,371,591 persons in the United States, according to the census of 1850, or one in 2,073; and but 96 of the same class among a free coloured population of 251,205, or one in 2,953. The number of blind among the former class amounts to 7,997. A comparison of the numbers of deaf and dumb, blind, insane, and idiotic, in the whole Union, with the population of the same colour and condition, gives the following proportions:—

	Deaf and Dumb.	Blind.	Insane.	Idiotic.
Whites.....	1 in 2,073	1 in 2,455	1 in 1,295	1 in 1,384
Free Coloured	1 " 2,956	1 " 867	1 " 1,355	1 " 983
Slaves.....	1 " 6,552	1 " 2,640	1 " 11,011	1 " 3,081
Total Slaves & Free Coloured	1 " 5,730	1 " 2,131	1 " 5,936	1 " 2,461

"It will be perceived from this, that blindness is more prevalent, and deafness and insanity less frequent, among the coloured races than among the white. The proportion of insane among the slaves is remarkably small. Perhaps the returns of the idiotic among the slaves are defective, as their large proportion among the free coloured seems to show that idiocy is more common among the coloured races than among the whites. In a large body of slaves, those only partially idiotic, or deaf and dumb, might be forgotten or overlooked by the master or overseer (who filled the schedule), being, in many cases, still useful hands, while the blind and insane would be more likely to be remembered.

"It appears that the deaf and dumb and the blind are most numerous in those States from which the emigration is greatest (the Central and New England), and least in those States whose population receive accessions from immigration—showing that comparatively few of these two classes of persons are carried along with the stream of emigration. In California, Utah, and Oregon (omitted in the foregoing calculations, on account of their recent settlement and peculiar circumstances), where the population consists almost wholly of recent immigrants, there are only six deaf and dumb, and two blind, in an aggregate population of 184,370. New Mexico is also omitted in these calculations, its population being of a peculiar character, chiefly a mixture of Spanish and native Indian races, with but few Anglo-Americans."

DR. J. C. STEELE ON THE INCREASE OF SMALL-POX IN GLASGOW.

The following is an abridgement of an article published by Dr. J. C. STEELE in the *Glasgow Medical Journal* for April 1853.

A casual survey of the improved mortality bills in connexion with the city of Glasgow for the last seventeen years (since, previous to 1835, no mention is made of the causes of death), affords proof of the ravages to which Glasgow has been subjected by small-pox and typhus fever, both in the condition of ordinary prevalence, and in the occasional exacerbations which they periodically assume. During the past four years, the mortality returns from fever exhibit a gratifying diminution when compared with

a like interval for many years preceding; a diminution justly attributable to the improved condition of the working classes, as well as to a decrease in the number of casual poor; since there are few localities in which the connexion between famine and fever has been more strikingly illustrated, than in this city. Small-pox has observed during the same, and it is feared for a much longer period antecedent, a high and even increased rate of mortality; notwithstanding the agencies in daily use for the purpose of prevention, and in spite of the enlarged powers afforded to vaccination boards, as well as to the local guardians of the poor, for the universal adoption of these checks.

The purposes of the present paper are to inquire, whether, and to what extent, small-pox has increased of late years in Glasgow; and how far vaccination has relieved the mass of the population from the disease. And there are other matters allied to the questions at issue, which must be incorporated with the following remarks. While singling out one subdivision in the class of zymotic affections for special comment, I admit that there are grounds for gratulation at the improvement which the mortality bills have exhibited for several years, in relation to the health and average mortality of our adult population. Dr. Strang's interesting Reports on the Mortality Bills,* compared with data of an analogous nature, taken from the Reports of the Registrar-General, show that, exclusive of the large infantile mortality, there are few cities capable of exhibiting such a marked immunity from the diseases destructive to adult life. These very circumstances, however, afford negative proofs of the importance of examining minutely into those causes of mortality that are operating in the midst of increasing prosperity.

We possess materials for investigating the history of small-pox in Glasgow, extending as far back as 1783. Dr. Robert Watt prepared tables from the parochial registers; and among other valuable information, there is a statement detailing the number of deaths occurring annually in Glasgow for thirty years subsequent to 1782, as also the annual number of deaths from small-pox during the same period.† These returns show the annual ravages of small-pox among the young, at a time when inoculation was generally had recourse to; as well as the beneficial results which flowed from the adoption of vaccination. During the first decennium of the above period, the mortality from small-pox, compared with the total number of deaths under ten years of age, was as high as 34·9, or one in three; while in the last decennium, that is, from 1803 to 1812 inclusive, a period when vaccination was all but universally followed, it had decreased to 0·2. From 1812 to 1835 no record of the deaths from small-pox has been kept. Since the year 1821, annual bills of mortality have been issued under the sanction of the lord provost and magistrates; but Dr. Cleland, at whose suggestion these were instituted, and who afterwards superintended their publication, gave no list of the diseases attended with fatal results. We are, therefore, left in conjecture with respect to the estimated prevalence of small-pox previous to 1835, although Dr. Robert Cowan was strongly of opinion that the disease had considerably increased before that period. Dr. Scott Orr has shown, in a table; constructed from the Glasgow Bills of Mortality from 1836 to 1845 inclusive, that during the latter half of this decade the mortality from small-pox was undergoing a favourable diminution, and hence he doubted that the disease was on the increase. The apparent diminution, however, will be observed, by reference to the following table, which I have extended to the close of 1852, to have been only temporary; and it affords a marked instance of the periodic revolutions to which all contagious maladies are subject:—

Years.	Estim. Popul.	Deaths from Small-pox.	Years.	Estim. Popul.	Deaths from Small-pox.
1835	230,860	473	1844	305,534	99
1836	238,950	577	1845	313,334	195
1837	247,040	352	1846	321,134	5
1838	255,300	388	1847	328,934	592
1839	264,010	406	1848	336,734	300
1840	272,000	455	1849	344,534	366
1841	282,134	347	1850	352,336	456
1842	289,934	334	1851	360,138	618
1843	297,735	151	1852	370,000	584

* The praiseworthy efforts recently made by the Lord Provost and magistrates to conform the Mortality Bills for Glasgow with the plan adopted by the Registrar-General of England, has been attended with greater success than the most sanguine could have anticipated. It is by no means complimentary to Scotland, that it should now be the only catholic country in Europe wherein a proper Register of Mortality is wanting. As far as Glasgow is concerned, the local authorities may justly claim the credit of removing the stigma, independent of legislative interference.

† Appendix to Treatise on Hooping Cough.

‡ Edinburgh Medical and Surgical Journal, No. 171.

§ The Returns for 1846 have not been published.

More than half a century has elapsed since the antivariolous efficacy of vaccination was first established in this city; and in the intervening period no exertions have been spared, either by the authorities or the medical faculty, to impress upon all classes its protective agency. It is lamentable to reflect, that the first two years in the last half of the nineteenth century should exhibit a larger mortality from small-pox than any similar period of which we have a record since the introduction of vaccination; and that they even outnumber in fatality the returns of a like period during the preceding century, when variolous inoculation was the only protective resorted to. The continued prevalence of the malady is doubtless mainly attributable to unjustifiable carelessness on the part of the poor, since the mortality has been chiefly confined to the infantile population; but it has also extended itself, though in a more mitigated form, to those previously vaccinated; and not a few adults also have fallen victims to the disease. The means of ascertaining the relative proportions of vaccinated and unprotected, in a given mass of population, are necessarily limited. Out of 244 individuals placed in similar circumstances to the poor in Glasgow, Dr. Stark discovered that only 116, or less than the half, were vaccinated; that 104 of the remainder had already taken small-pox, leaving 24 still unprotected.* The ascertained results of practice in the Glasgow Royal Infirmary are exceedingly instructive as regards many questions in the pathology of small-pox. The returns, however, are only applicable to the disease in adults. The same rule holds with respect to other epidemics peculiar to children, as measles, scarlatina, and hooping-cough. On the other hand, so general has the habit become of sending all affected with fever—a disease of adult life—to the hospital, that during several stated periods for last year, the fatal cases from this disease in the hospital corresponded with the mortality returns for the whole city and suburbs.

The universality of small-pox gives it an intermediate position; and from the data furnished in the hospital, its prevalence among the adult portion of the community has been considerably on the increase for many years. Previous to 1834, the number of cases admitted seldom reached above 30 in the course of a year, and several years do not yield a single example. From 1795 to 1804 inclusive, the numbers admitted amounted to 22; and during ten years subsequent to 1804, they had only reached to 33. From 1815 to 1825, 163 cases are reported as having occurred. Judging from a considerable increase in 1823-4, there appears to have been an epidemic of small-pox at the period, inasmuch as the numbers for each year respectively amount to 46 and 37, and conjointly present a larger number than were admitted during the first twenty-two years of the history of the institution. From 1825 to 1835, the cases admitted amounted to 204, the last two years of the decennium furnishing 132 of that number. The following table exhibits the numbers and mortality of the cases admitted from 1832 till the present time, arranged in septennial periods:—

Years.	No. of Cases.	No. of Deaths.	Years.	No. of Cases.	No. of Deaths.	Years.	No. of Cases.	No. of Deaths.
1832	3	1	1839	59	15	1846	99	10
1833	14	5	1840	61	18	1847	84	21
1834	62	4	1841	26	0	1848	48	13
1835	72	18	1842	38	5	1849	43	12
1836	110	45	1843	13	3	1850	78	18
1837	75	8	1844	10	0	1851	163	30
1838	35	10	1845	22	4	1852	115	19
Mortality per cent. 1st Period, 24·5.			2nd Period, 19·2.			3rd Period, 19·5.		

The interval between 1835 and 1838 comprises a period when the deaths from epidemic causes in Glasgow appear to have reached their maximum; the rate of mortality, exclusive of still-born, in 1837, rising as high as 1 in every 24 of the population. This unusual fatality was chiefly accounted for by the ravages of fever, no fewer than 3433 individuals having been cut off by this disease alone. The returns for 1836 were greatly augmented by an increased prevalence of small-pox, which told most severely on the young; the number of deaths under five years amounting to 520, or nearly 92 per cent. of the whole cases. Out of 110 adults attacked during the same period; 45 cases terminated fatally; a very large comparative mortality, and indicative of an unusually large number of unprotected. The most important features in the table are the diminished rates of mortality which the two last periods present, and the increase in the number of cases which the last septennial system exhibits. How these conflicting circumstances are to be explained, becomes a question of vital importance in its bearing on the future history of the disease.

* Edinburgh Medical and Surgical Journal, No. 322.

Few doubt that small-pox has increased in frequency in this country during the last twenty years, and most observers have attributed the change to a neglect of vaccination. That this neglect has prevailed, and is still prevailing in Glasgow, especially among the children of the Irish poor, there can be little doubt; but that vaccination is more generally neglected now than formerly, is open to question. The prevalence of small-pox among the protected is by no means so rare as is generally supposed. The proportion of post vaccine cases treated in hospital is actually larger than the number of unprotected, and instances of the former class have been considerably on the increase for some years.

I am indebted for the materials used in the construction of the following table to the published investigations of Drs. Cowan,* Orr,† and A. P. Stewart;‡ the data furnished by the last three years of the series being the result of my own inquiries. The doubtful cases have been purposely omitted:—

Year.	Total.	Vaccinated.	Unvaccinated.	Deaths in	
				Vaccinated.	Unvaccinated.
1836	95	55	40		26
1837-38	71	31	40	1	15
1846	99	47	52	2	8
1849	42	23	19	3	8
1851	128	52	76	8	17
1852	101	57	44	5	12
Total,	536	265	271	19	86

The advantages of vaccination are here vividly illustrated; for while the per centage mortality among the unprotected reaches 31.8, the post vaccine deaths amount to 7.1. With but few exceptions, the post vaccine cases have occurred after the age of puberty; and the disposition of the disease to attack at that period would lead us to infer that certain constitutional changes are liable to take place among many people, which render them more susceptible of the variolous miasm. Statistics drawn from other sources tend to corroborate these results. Out of 1519 admissions to the Small-pox Hospital, from 1826 to 1839 inclusive, and reported by the late Dr. Gregory,§ as having small-pox at variable periods after vaccination, 100 terminated fatally. Over the whole cases, the proportion of vaccinated and unprotected is nearly equal; and while the numbers diminish in an unequal ratio for one year, they usually reverse the process in the next. It would seem that when an epidemic of small-pox begins to decline in severity—that is to say, after it has reached its culminating point—it exhibits a greater tendency to attack the previously vaccinated than it showed at the outset. In a report recently read to the governors and subscribers of the London Small-pox Hospital,|| it appears that, during the last year, a larger number of patients have been admitted than were ever treated for a similar interval since the foundation of the hospital in 1746. In 1851, the admissions amounted to 682, out of which only 230 were vaccinated; and during last year, 1852, the admissions had risen to 800, and showed an increase of post vaccine cases, over 1851, of no fewer than 120.

The form which the disease assumes is to be borne in mind when speculating on the ultimate issue of the two classes. In the following table I have analyzed 101 cases treated to a termination during 1852, reducing the forms, for convenience of description, to discrete and confluent small-pox:—

<i>Confluent and Malignant Small-pox.</i>				<i>Discrete and Modified Small-pox.</i>			
	Total.	Cured.	Died.		Total.	Cured.	Died.
Males, vaccinated .	7	5	2	Males, vaccinated .	26	24	2
Females, do.	7	6	1	Females, do.	17	17	0
Males, unvaccinated	16	8	8	Males, unvaccinated	8	8	0
Females, do.	11	7	4	Females, do.	9	9	0
Total.	41	26	15	Total.	60	58	2

Hence, out of 44 unprotected individuals, 27 were attacked severely, while 17 escaped with a mitigated illness. The two deaths among the discrete cases were produced by internal inflammatory complications. It will be observed that males have suffered more, both in numbers and fatality, than females. An example illustrative of the non-identity of small-pox with vaccinia occurred in a female, whose case is incorporated in the number of discrete

and vaccinated cases. Several days previous to the attack she had been vaccinated; and on admission the vaccine vesicle was found fully matured. The two diseases proceeded simultaneously to a favourable termination, without apparently interfering with each other's progress.

Cases of secondary or recurrent small-pox are rarely met with in this hospital. In the course of my inquiries, I have been able to discover one instance only.

The disposition of small-pox to attack individuals, immediately on their transference from an open and salubrious locality to one in which the disease constantly prevails, is a feature of considerable importance in its pathology. This remark, however, is not applicable to children. The following table, detailing the length of residence in Glasgow of the 101 cases formerly cited, will enable us to judge of the comparative frequency of small-pox among recent residents:—

Under two weeks	10	From five to six months	19
From two to four weeks	14	From six to twelve months	19

No fewer than 81 individuals out of 101 had been less than twelve months resident in Glasgow, and 24 of this number had been less than one month. The peculiar susceptibility among recent residents no doubt is greater when the variolous miasm spreads epidemically; but it would be difficult to find more corroborative evidence of the influence of climate and residence than that presented by the preceding table.

We are next led to trace the various localities from which patients have come, or where they may have spent the early period of their lives. The following table shows in what parts of the West of Scotland vaccination is chiefly neglected: it incorporates the results of 1849 with those of 1852, and extends over 143 cases of the disease:—

Birth-place.	Tot. Cases.	Va.	Unv.	Birth-place.	Tot. Cases.	Va.	Unv.
Argyleshire	56	24	32	Counties south of			
Inverness-shire	7	5	2	Forth and Clyde	35	30	5
Aberdeenshire	4	3	1	Born in Glasgow	4	1	3
Ross-shire	3	1	2	England	3	3	0
Sutherlandshire	2	1	1	Ireland	19	9	10
Perthshire	5	1	4	Foreign Countries	4	2	2
Shetland	1	0	1				
				Total.	143	80	63

Hence, out of 63 unprotected cases, 43 have been natives of the Highlands, 10 were born in Ireland, 5 in Lanarkshire and the neighbouring counties, and 3 had been permanently resident in the city. The greater liability of the Highland population is no new feature in the local history of small-pox. Twenty years ago Dr. Cowan drew attention to the fact, and there are few medical men in Glasgow who have not had ample evidence of the same. Nor is it the case that the Highland poor show a decided aversion to vaccination. The proverbial laxity prevailing among them regarding the practice, probably arises more from ignorance of its benefits, than from prejudice or unwillingness to adopt it. The prejudice in favour of variolous inoculation, which prevails in various parts of England notwithstanding the legal enactment of 1840, does not appear to extend itself to any part of Scotland. In the country parishes, and to a less extent in the towns, the poor are largely influenced by their clergy, whose labours to advance the social as well as the spiritual well-being of the people are universally acknowledged. By this class especially, seconded by the united exertions of the parochial authorities throughout the Highlands, much good remains to be effected. It is to be regretted, however, that in many districts, the difficulty of obtaining the services of a medical man to perform vaccination militates against its general adoption. The sequestered islands of Coll and Tiree, in which small-pox seems only to be known by occasional importation from the low country, annually contribute their quota of unprotected to the small-pox wards; and the minister of these islands writes, that several lives are annually lost in the parish from the want of a medical practitioner.*

It is interesting to observe with what tenacity small-pox clings to the Scotch branch of the Celtic inhabitants in preference to the Irish, a feature rendered more striking by the disproportion which the former bear to the latter in the population. While the Highlanders form 44 per cent. of the cases analyzed in the preceding table, natives of Ireland amount to only 13 per cent. In the various forms of continued and typhus fever, natives of

* New Statistical Account of Scotland.

Ireland average usually from 60 to 65 per cent. of the whole admissions to the Fever Hospital; and in the ordinary medico-surgical wards, the number is never below 35 per cent.

The ages of the individuals attacked with small-pox is the next step in investigation. In the unprotected state, the liability of attack at all ages is well known. It is different, however, with the vaccinated. The following table includes only the 57 cases who had small-pox after vaccination, in 1852; of these there were,

Under five years . . .	3	From twenty-five to thirty . .	8
From five to ten . . .	2	From thirty to forty . . .	3
From ten to fifteen . .	1	Upwards of forty . . .	0
From fifteen to twenty .	21		
From twenty to twenty-five	19	Total . . .	57

The interval between the period of vaccination and the onset of the disease thus ranges from one to thirty-five years; but the disposition to attack has reached its maximum between fifteen and twenty-five, no fewer than 40 cases out of the 57 occurring during this decennium. After the age of thirty, it does not appear that the liabilities are so numerous. Out of 298 post vaccine cases occurring in 1838, in the London Small-pox Hospital,* only 17 were above the age of thirty, and 14 of these were below thirty-five. The major part of the unprotected treated in 1852, in the Glasgow Hospital, occurred immediately after puberty; only 3 being above the age of twenty-five. The infantile period affords, in Glasgow, by far the largest number of deaths from small-pox; but as children are mostly debarred from admission to hospital, the data are too limited for analytical purposes. From the Monthly Returns of Mortality for the city and suburbs of Glasgow, I have been enabled to form the following table, detailing the number, sex, and age of the individuals cut off by small-pox in the course of 1852. The total deaths amounted to 584, of which there occurred—

	Total.	M.	F.		Total.	M.	F.
Under 1 year . . .	188	96	92	From 25 to 30 yrs	2	1	1
From 1 to 2 . . .	150	72	78	From 30 to 40 . .	8	4	4
From 2 to 5 . . .	189	101	88	From 40 to 50 . .	1	1	0
From 5 to 10 . . .	20	13	7	From 50 upwd . .	1	0	1
From 10 to 15 . . .	4	1	3				
From 15 to 20 . . .	2	0	2	Total . . .	584	300	284
From 20 to 25 . . .	19	11	8				

Hence, among the total deaths from small-pox in 1852, 527 were under five years of age, 24 occurred between the ages of five and fifteen, and 33, or 1 in 17½, took place after the period of puberty. In comparing the data with the returns of 1835-36, we find little variation in the proportion of deaths to the various ages:

	Under 1 year.	1 to 2.	2 to 5.	5 to 10.	Above 10.	Total.
1835 . . .	204	154	75	17	23	473
1836 . . .	202	174	144	23	34	577
1852 . . .	188	150	189	20	37	584

For the three years, the annual average number of deaths under 10 years of age amounts to about 513; and when compared with the average returns for ten years after the introduction of vaccination, they exhibit an increase of more than 400 annually. It is necessary to bear in mind the great increase of population which has taken place in Glasgow during the last half century. But after making due allowance for this in the case of small-pox, it will still be found that the number of deaths resulting therefrom, when compared with that in localities where vaccination is sedulously attended to, is inexcusably large. In the city of Paris, with a population of one million, the number of deaths from small-pox in 1850 was 342, and in 1851 it amounted to 364;† while in Glasgow, with its population of 370,000, no fewer than 1,202 deaths from the same cause have occurred during the last two years. In no country in Europe, with perhaps the doubtful exception of Prussia, is vaccination so thoroughly attended to as in France. It will be interesting, therefore, to know the relative ages at which small-pox proved fatal in Paris in a given number of cases. The following table represents the ages of 706 individuals cut off by small-pox in Paris during the period above noticed:

	Total	M.	F.		Total	M.	F.
Under 1 year . . .	126	62	64	From 25 to 30 . . .	89	58	31
From 1 to 2 . . .	32	17	15	From 30 to 40 . . .	128	72	56
From 2 to 5 . . .	94	52	42	From 40 to 50 . . .	22	13	9
From 5 to 10 . . .	31	16	15	From 50 upwards . .	4	3	1
From 10 to 15 . . .	20	12	8				
From 15 to 20 . . .	51	34	17	Total . . .	706	402	304
From 20 to 25 . . .	109	63	46				

* Lectures on Eruptive Fevers.

† Annuaire pour l'an 1853-54.

While this table shows the ages at which small-pox is likely to prove fatal, in a community in which vaccination is all but universally adopted, the table referable to Glasgow must, we fear, be considered as indicative of a locality in which vaccination is egregiously neglected. In Paris, the number of deaths under 5 years amounts only to 35·6 per cent., and in Glasgow the same period of life furnishes 90 per cent. of the total cases. It scarcely admits of doubt, that the comparatively large figure of mortality in Paris after 15 years, has originated, to a considerable extent, among the previously vaccinated. On no other ground can we explain the fact of more deaths occurring between the ages of 30 and 40 than in the infant period of life, during which, in the unprotected state, two-thirds of children are attacked by small-pox; and, on an average, 1 out of every 3 attacked dies. The Bulletins of the Royal Academy of Medicine, however, show that, during the mid-period of the last half century, in consequence of the rigid enforcement of vaccination, the deaths in Paris alone fell from 1,090 to an annual average of 420; and more recent returns exhibit a further diminution to 353.

From the observations already made, the inference naturally forces itself, that at certain ages, and under peculiar circumstances, the most prominent of which are change of residence and exposure to concentrated miasm, the constitution becomes re-susceptible of the variolous poison, notwithstanding the vaccine protection. This susceptibility has not manifested itself to a very fatal extent in the returns adduced relative to Glasgow, chiefly from the reason, that those predisposed to contract the affection are for the most part visited with it in early life; and that, in the event of recovery, the primary attack affords a safeguard for the future. To remedy this defect in the permanent influence of cow-pock, recourse has been frequently had to re-vaccination; and the process is generally recommended, though not so frequently adopted by medical men. So common, indeed, has post vaccine small-pox become in several countries on the Continent, that the governments of Denmark and Prussia, impressed with the importance of the protective agent, issued orders many years ago for the revaccination of their standing armies. The success of a similar trial in Württemberg has induced the authorities of that country to extend the operation to the whole civil population. Its propriety has been called in question, in consequence of small-pox occurring after a second and even after a third vaccination; but it is unjust to argue, on this ground alone, that re-vaccination is entirely useless. The expedient is safe and harmless, and its practice is peculiarly applicable at the present time, for the future protection of the emigrating class of the community.

The beneficial results of the operation of the Vaccination Act of 1840 in England and Wales warrant the inference, that it would have been attended with similar advantages in Scotland; but it is questionable whether the working of the act has fulfilled the expectations of its originators. Besides the rendering the practice of inoculation illegal, it is equally desirable that the non-performance of vaccination should be considered illegal also. It is only by some stringent measure of this kind that the protective agent will become universal; and when universal, it can only be considered as a means of greatly mitigating the mortality and prevalence of the disease. Medical authorities in this country are at variance as to the comparative merits of inoculation and vaccination; but, by reason of the enactment, the majority are restricted to the latter alternative. In Scotland, where no such law prevails, a similar practice is generally followed, since few would risk the danger of spreading real small-pox by the foci of contagion, which inoculation must originate. Of the two means of protection, one affords a sure, the other a doubtful, safeguard against small-pox; but the advantages in favour of the former are more than counterbalanced by the host of evils that would ensue, unless the practice were universally adopted. With a knowledge of these facts, it is surely the duty of all who are interested in the welfare of, and intrusted with the management of the poor, to exert every legitimate means in their power to check the ravages of small-pox. It may be argued, that few places offer more facilities and better opportunities for universal vaccination than Glasgow; that there are five separate stations throughout the city where vaccination is performed gratuitously, and that it is rendered incumbent on the parochial surgeons to be constantly supplied with lymph, and be at all times ready to vaccinate the poor in their own localities. That all these measures have proved inefficient in checking the increasing evil, has been fully demonstrated; and it now only remains to suggest a remedy more efficacious than any hitherto had recourse to.

It is useless to anticipate more benefit by the same means.

of additional stations for vaccination. If, by authoritative arrangement or otherwise, it were rendered imperative on every parent, and also on the clergy of every denomination, to see that vaccination was only performed before the child received baptism, our annual mortality would be most materially diminished. Another plan would be, to make it incumbent on the individual who superintends the delivery of the child, whether accoucheur, midwife, or medical student, to see that it is properly vaccinated within a given period after birth. The absence of a proper system of registration in Scotland necessarily precludes the possibility of enforcing any measure relative to vaccination, that might have an analysis of the actual births as a groundwork for its operation; and an increased responsibility is thereby entailed on the parochial boards. The subject is doubtless beset with many difficulties; but there are few evils of any magnitude that are not equally surrounded, and for the removal of which the enforcement of some stringent practical remedy is not absolutely necessary.

SURGERY.

CASES OF RECOVERY AFTER LOSS OF PORTIONS OF THE BRAIN.

Instances have been from time to time recorded, in which portions of the substance of the brain have been lost through injury, and in which the patients have completely recovered.

Mr. Guthrie, in his work on *Injuries of the Head affecting the Brain*, says: "One man shall lose a considerable portion of his brain without its being productive at the moment, or even after his restoration to health, of the slightest apparent functional inconvenience; whilst another shall fall, and shortly die, without an effort at recovery, in spite of any treatment which may be bestowed upon him, after a very much slighter injury inflicted apparently on the same part. . . . The result of my experience on this point is, that brain is more rarely lost from the fore part of the head with impunity, than from the middle part. . . . I have never seen a person recover with a foreign body lodged in the anterior lobe of the brain, although I have seen several recover with a loss of a portion of the brain at this part."

The following collection of such cases will show that they are perhaps more common than is generally supposed.

CASE I. Dr. JAS. YONGE, of Plymouth, the author of the *Curvus Triumphalis e Terebintho*, in a small work on *Wounds of the Brain proved Curable*, published in 1682, relates, with much minuteness, the case of a child, four years old, who came under his care on account of being injured by a heavy field-gate falling on him. The head was crushed between a stone on the ground, which bore on the left side somewhat above the ear, and a pin of wood standing out half an inch from the gate on the other side. Before Dr. Yonge saw the child, it had bled much; it had not fainted nor been convulsed, but had vomited two or three times. In examining the wound, Dr. Yonge found depression of a portion of the skull on the right side, where it had come in contact with the wooden pin, and removed several pieces of brain from the wound. On the other side there was also fracture with depression. A large portion of bone was removed; the wound on the left side was healed in seven weeks; that on the right side in three months.

In an appendix, Dr. Yonge has collected the opinions of sixty authors, who affirm that wounds of the brain are curable, and confirm these statements by above a hundred observations. Among these are Galen, who, in his *Commentaries on the Aphorisms of Hippocrates*, says that he has several times seen recovery after injury of the brain—especially a case at Smyrna; Jacobus Corvus, who, in his *Tractatus de Fractura Cranii*, says, "Up to the present time, I have seen six persons, from whom a notable quantity of brain escaped, and they yet recovered"; Guy of Chauliac, who is quoted as having seen a person who had a wound of the back part of the head, with loss of a small portion of the brain, and recovery; Gabriel Fallopius, who says that he saw a gipsy, who, in the month of January, received an extensive wound in the head from a partisan, with loss of as much brain as could be contained in a hen's egg, but recovered; and who also says, that he has seen several patients who had lost portions of brain, and remained insensible for some time, some of whom lived for a hundred and twenty days, while others recovered. We could quote several more instances from this interesting contribution to medical history; but we can merely mention the names, supplied by Dr. Yonge, of Fabricius ab Aquapendente, Zacutus Lusitanus, Veslingius, Jacques Guillemeau, Ambroise Paré, Fabricius Hildanus, Sen-

nertus, Scultetus, Fernelius, Thomas Bartholinus, etc., etc., all of whom bear witness to the possibility of recovery after loss of portions of the cerebral substance.

CASE II. In the *Edinburgh Medical and Surgical Journal* for January 1816, Mr. C. K. CRAWFORD relates the case of a boy, aged between two and three years, who received fracture and depression of the left parietal bone. About the bulk of a walnut of brain was lost. In the course of the case, hernia cerebri occurred, and was successfully treated by compresses and bandages. The report of the case closes with stating the child to be "clever, healthy, and apt, and not in the least injured by the accident".

CASE III. This case is related by Mr. JOHN EDMONDSON, of Keswick, at page 199 of the *Edinburgh Medical and Surgical Journal* for April 1823. On August 2nd, 1822, C. H., aged 15, was wounded by the bursting of an over-loaded brass cannon. The frontal bone was fractured, and a portion, two and a half inches long by one and a quarter broad, including the frontal spine, was removed; as were also other smaller portions of various sizes, in all thirty-two in number. More than a table-spoonful of cerebral substance came away at the time. Portions of brain were also discharged at three dressings, becoming less each time. At no period were there any symptoms referable to this injury; during the time that the brain was discharged, he is reported as "giving correct answers to questions put to him", and as being "perfectly rational". On October 27th, the wound, from which there had been free supuration, was completely closed; and on November 7th, he was reported in perfect health, and as having suffered no derangement of his mental faculties.

CASE IV. In the *Bulletin de l'Académie Royale de Médecine* for April 1842, is mentioned a case related by M. POIRROUX, in which a young man, aged 20, received a blow with a stone on the right side of his forehead. He instantly fell; but, recovering his senses, got up, and was able to walk. No paralytic symptoms ever appeared. The skull was deeply driven in; the soft parts were severely injured; and a portion of brain had escaped from the wound. Copious supuration soon commenced, when several additional portions of brain escaped along with the purulent matter. The patient recovered without having had a bad symptom.

CASE V. A case is related by Dr. ROGERS in the *Medico-Chirurgical Transactions* for 1827. A young man, aged 19, received a wound on the frontal bone just above the centre of the left supraciliary ridge, from the bursting of a gun, on 10th July. It was not until the 4th of August that he discovered a piece of iron lodged within the head in the bottom of the wound, from which a considerable quantity of bone had come away. On extracting it the next day, it proved to be the breech-pin of the gun, three inches in length, and three ounces in weight. On the 10th of December, he was perfectly cured.

CASE VI. Dr. H. BIGELOW relates, in the *American Journal of the Medical Sciences* for July 1850, the case of a man, aged 25, who, on September 13th, 1848, had an iron rod driven through his head by the exploding of some gunpowder, while engaged in preparing a rock for blasting. The iron passed from the angle of the lower jaw to the centre of the frontal bone, near the sagittal suture. He was at first rendered insensible, and was slightly convulsed; but soon recovered his consciousness and power of speech. There was considerable hemorrhage. The daily progress of the case is reported by Dr. Harlow, under whose care the patient was. No remarkable symptom appeared till the 18th September, when he became delirious; and, from the 23rd of that month till the 3rd October, he lay in a semi-comatose state, answering only in monosyllables when spoken to. During this time, also, he had lost the sight of the left eye, and an abscess had formed under the occipito-frontalis muscle. After this, he recovered gradually, with the exception of the effects of a chill, from getting wet in the feet while walking out on 14th November. The symptoms were subdued in a few days; and, on the 18th, he was reported as in a fair way of recovery.

In January 1850, he was seen by Dr. Bigelow. There was ptosis of the left eyelid, and the eye was incapable of being moved outwards or upwards. The situations of the orifices of the wound were occupied by cicatrices.

Dr. Bigelow performed some experiments on the dried skull, to ascertain precisely what parts must have been injured. He found that the iron entered beneath the zygoma, removing the orbital portion of the sphenoid, the anterior part of the squamous portion of the temporal bone, and the internal surface of the zygoma and malar bone laterally. In the orbit, the

sphenoid bone, part of the superior maxillary, and a large part of the frontal, were removed, leaving the optic foramen intact. At the base of the skull, the frontal, temporal, and sphenoid bones were cut. In the brain, the central part of the left anterior lobe, and the front of the middle lobe, must have been destroyed, laying open the lateral sinus. The falx and longitudinal sinus must also have been lacerated.

The instrument weighed thirteen pounds and a quarter, was three feet seven inches in length, and was one inch and a quarter in diameter. At the end which entered the head, it tapered off for seven inches, till its diameter was a quarter of an inch at the point.

In the *Canada Medical Journal* for May 1852, Dr. F. S. VERITY relates the following case.

CASE VII. D. C., aged 14, while teasing a horse, was kicked on the side of the head. He fell down senseless. On examination an hour after the accident, Dr. Verity found a fracture of the skull between the right parietal and temporal bones. On the external surface of the wound, which had bled very freely, there were small portions of bone and brain mixed in a clot of blood; on removing these, a detached portion of bone was found imbedded in the brain. On removing this, several portions of brain escaped, the largest of which was about the size of a hazel-nut. The patient remained comatose; the pulse was 60, the countenance pale, and the breathing heavy. Reaction took place in twenty-four hours, which was successfully treated by cold applications to the head, and by brisk purgatives. In two days, sensation returned; at the end of a week, the patient was perfectly conscious, and in a month was quite well. Portions of the brain came away at the first three dressings.

In the *Monthly Journal of Medical Science* for September 1845, a case of a gun-shot wound of the brain, followed by recovery, is related by Mr. C. G. E. FORD, of the Madras Medical Establishment.

CASE VIII. A boy, aged 15, was shot in the head, apparently accidentally, during the practice of a regiment. When discovered, he was insensible, and breathed stertuously. The ball had passed through from three-fourths of an inch in front of the summit of the right ear, and to an inch and a quarter above the centre of the left eyebrow. The skull was fractured irregularly between the wounds, also from the place of entrance to the lambdoidal suture, and over the sinus of the right os frontis. In the process of the case, portions of brain were discharged; there were delirium, and involuntary evacuations; but he gradually but perfectly recovered his intellect and memory and senses.

CASE IX. This case is related by Dr. DE BARBE, of Chaumes, in the *Gazette des Hôpitaux* for 5th February 1853. The patient was a man, aged 25, who was wounded by the bursting of his gun, a portion of which penetrated the skull above the centre of the left eyebrow. He was able to search for the fragments of the gun, and to walk some distance to a hospital. When the piece of the gun was removed, a spoonful of cerebral matter escaped. There was no disturbance of intellect, nor of the senses, nor of speech, throughout the progress of the case. On the twelfth day, the patient was discharged cured.

In the *Gazette des Hôpitaux* for 10th February 1853, M. CHASSAGNAC relates some cases, with the object of showing that injuries of the brain are not only less fatal than is commonly supposed, but are even less frequently followed by severe symptoms.

CASE X. A farmer, named Meen, was wounded in the head while discharging his gun, by a piece of the breech. It pierced the frontal bone about an inch and a half above the border of the left orbit, and entered the brain, driving before it a round piece of his hat and several fragments of bone. He had no troublesome symptoms, beyond an attack of epilepsy.

CASE XI. In a young man, aged 17, a musket-ball entered the upper lip, and passing upwards, traversed the right nostril, and entered the skull through the floor of the orbit, whence it made its exit through the upper part of the frontal bone, near the sagittal suture. In this part there was a fracture extending as far as the parietal bone, and a large wound, with loss of substance in the integuments. After the extraction of the splintered portions of bone, and the escape of several portions of brain, there were severe symptoms; but these ceased on the nineteenth day, and the patient recovered.

CASE XII. A soldier received a gunshot wound in the head at the first revolt in Cairo. The ball entered the middle of the frontal bone, near the sinus, and passed obliquely backwards between the skull and the dura mater, thus traversing the course of the longitudinal sinus as far as the occipital suture,

where it stopped. Trephining was performed, in consequence of some symptoms of compression. The foreign body was removed, and recovery took place without any unfavourable symptoms.

CASE XIII. At the battle of Waterloo, a ball entered the outer side of the left frontal bone, near the left orbit, and buried itself at a point corresponding to the curved line in the temporal fossa. The patient had involuntary discharge of urine and faeces, hemiplegia of the left side, and loss of memory of proper names, and of some names of objects. He recovered from these symptoms, rejoined the service, and died of phthisis in 1827.

CASE XIV. G., aged 21, was, while discharging his gun, wounded in the forehead by the breech-pin, which buried itself in the lower part of the frontal bone, immediately above the nasal spine. The wound extended to the left, including the internal angle of the orbit, as well as a portion of the front of its upper surface and the projection of the eyelid. There was escape of cerebral substance. No severe symptom occurred; and recovery took place in less than twenty-four days.

CASE XV. A young man, aged 22, was discharging a gun; it burst, and he received in the frontal bone, a little above the border of the orbit, a piece of the breech-pin, which penetrated an inch and a half into the brain, driving before it a fragment of bone three quarters of an inch in diameter. The stones near the place where the accident occurred, were soiled with debris of cerebral substance, and with a little blood.

CASE XVI. The cause of the injury was here unknown. On making a *post mortem* examination (after death, from some other cause), there was found to be a fracture of the frontal bone, with penetration of the fragments into the brain.

CASE XVII. A man, aged 32, was wounded in the head by the bursting of some fireworks. There was a large wound on the left side in front, with laceration of the dura mater, and escape of cerebral pulp. This patient died; but it is to be observed that he was able to walk for some minutes a quarter of an hour after the accident, to sleep the next night, and to be carried the next day in a boat on the Rhone to the Hôtel-Dieu, at Lyons; that he preserved entire for thirty-two days his intellect, sensation, and motion; and that it was only at the end of that time that these functions gradually became disturbed, and fatal symptoms supervened.

The following case is related in the *Medical Times and Gazette* for April 23rd.

CASE XVIII. William Rogers, aged 2½, a strong healthy looking child, was admitted into St. Thomas's Hospital under Mr. South, on September 7th, 1852. About two hours before admission, he had fallen down an area ten feet in depth. When picked up, he was screaming violently, and bleeding copiously from a wound just above the left frontal eminence of the head. He did not seem to recognize or take notice of his parents. The wound was at once dressed by a surgeon. At that time there was no protrusion of the brain; but in about half an hour, a whitish substance was noticed to be protruding from the wound. On his admission into hospital, there was found to be a wound about an inch in length, in which was a detached portion of brain of the size of a kidney-bean. No fracture was detected in the wound, but an apparent depression backwards existed above it. The child was insensible, and the right side of the face and right arm were convulsed, but not violently; the pupils were dilated, and the left eye was closed by swelling. Just before admission, he had vomited the contents of his stomach, with a considerable quantity of clotted blood. During the dressing of the wound, he again vomited, and bled slightly from the nose. The pulse was 120, regular; the breathing tranquil. In about half an hour, he appeared to be sinking; but soon began to mend; he became partially sensible, the pupils answered to light, and the convulsions had ceased. No operation was considered necessary.

The subsequent report of the case shews that he went on favourably, without a bad symptom, and was discharged with the wound nearly healed on September 17th, ten days after the accident.

TREATMENT OF DISLOCATION COMPLICATED WITH FRACTURE.

M. RICHET, at a meeting of the Surgical Society of Paris, in 1852, reported in one of the numbers of the *Union Médicale*, read a memoir on the possibility of reducing dislocations of the humerus and femur, when complicated with fracture of the bone in the vicinity of the joint. He gave as his opinion that, by placing the patient under the influence of chloroform, and employing coaptation, without extension, the dislocation might be reduced.

before the fracture: in opposition to the doctrines of Boyer and Dupuytren. M. Richet employed this method successfully in a case of dislocation of the humerus with fracture of the surgical neck. He also demonstrated the practicability of the proceeding by experiments on the dead body. He proposed to apply the plan of coaptation to the treatment of dislocation in general, whether complicated with fracture or not.

In reporting on the essay of M. Richet, M. Gosselin stated the principal merit of the author to consist in having brought forward a plan of treatment which had indeed been employed by other individuals, but which was not generally known, from the cases being published in periodicals and theses, and hence inaccessible to many members of the profession. He objected to the use of chloroform so frequently as recommended by M. Richet: and believed that reduction by coaptation could often be accomplished during the state of prostration succeeding the injury. He thus summed up the proper treatment of fracture complicated with dislocation. "As soon as the lesion is discovered, no matter at what time, reduction by coaptation should be attempted, chloroform being given, if not contraindicated: and the operation should be repeated several times, if it does not at once succeed. If reduction is not obtained, and the upper fragment of the bone is large enough, extension should be combined with coaptation: the application of the starched bandage (*appareil inamovible*) is useful. If we do not then succeed, we must wait until the fracture is united, and then attempt to reduce the dislocation; and if we then fail, we must favour by passive motion the formation of a false joint."

In the *Revue Medico-Chirurgicale* for February 1853, M. MALGAIGNE gives a summary of the present state of knowledge on this subject: and adds the results of his own experience.

In seven years he has had under his care, in the hospital of St. Louis, thirteen cases of dislocation complicated with fracture, viz., one case of dislocation of the fourth cervical vertebra with fracture of the posterior arch: one of dislocation of the sacrum with fracture of one ilium: one of dislocation of an arm with fracture of a leg: one of dislocation backwards of the elbow with fracture of the fore-arm: one of dislocation backwards of the elbow with fracture of the radius: one of dislocation forwards of the radius, with fracture of the fore-arm: one of dislocation with fracture of the radius: three of dislocation of the lower end of the ulna with fracture of the radius: one of dislocation of the knee with fracture of the leg: one of dislocation of both knees with fracture of the left leg and arm: and one of dislocation of the tibio-tarsal joint with fracture of the tarsal bones.

Among these cases, those are the most frequent in which the fracture affects the luxated bone: this is most commonly found in the arm; then in the fore-arm, thigh, and leg.

From the attention of the surgeon being directed to the fracture, often to the exclusion of the dislocation; from the swelling being more rapid and considerable than in simple cases; and from the pain of the dislocation being masked by that of the fracture, the luxation is often not detected by the surgeon: and M. Malgaigne acknowledges that he has erred in this way in a case of dislocated humerus, and in one of dislocation backwards of the head of the radius.

When dislocation with fracture is recognized, how is it to be treated? Pasicrates, who wrote about half a century before the Christian era, and Oribasius, advise that the dislocation should be first reduced; and then the fracture. Arisdon preferred extension, so as to act on both at the same time. Celsus and Galen say nothing of the subject; and Paulus Egineta and Haly Abbas give very meagre instructions. Guy of Chauliac writes: "If dislocation is complicated with fracture, let the dislocation be first reduced, and then the fracture, if possible. But, if otherwise, let the fracture be reduced; and when the callus is firm, the dislocation may be treated." J. L. Petit quotes this precept, and adds that reduction of the dislocation is impossible when the fracture is near the joint. To this M. Malgaigne objects, first, that it is not the distance of the fracture which forms the great obstacle; secondly, that it is rarely that reduction must be effected by extension. Boyer properly admits that the luxations of the ginglymoid joints can be reduced without extension: but, with regard to the ball and socket joints, he says that dislocations cannot be reduced while fracture exists, and that, when the callus is solidified, the length of time opposes an obstacle. Sir A. Cooper advises immediate reduction of the dislocation in all cases, from fear of reproducing the fracture, if extension is employed subsequently.

In recent cases of dislocation, M. Malgaigne observes that mild means succeed best; such as pressure, impulsion, and rotation: and that the ball and socket joints are as amenable to this treatment as the others.

Delamotte, in his *Traité de Chirurgie*, relates a case of dislocation of the humerus, complicated with fracture of the bone near the junction of the upper with the middle third, and with fracture of the clavicle. The dislocation was reduced by an assistant pressing firmly on the acromion, while Delamotte "drew the head of the bone downwards, at the same time pressing it upwards": in fact, by a movement of rotation. Laroche (*Thèse Inaugurale*, Strasbourg, 1803) had a case of dislocation of the humerus under the clavicle, the bone being also broken at the lower third. Having had the acromion fixed, he pushed back the head of the humerus into the glenoid cavity. James Gordon (*Trans. of the Medico-Chir. Society of Edinburgh*, 1824) reduced in a similar manner a dislocation of the humerus, complicated with comminuted fracture of the bone. Houghton (*Lancet*, 1845) reduced on the tenth day a dislocation complicated with fracture four inches below the acromion.

Dupuytren (*Leçons Orales*, tome i, p. 85) asserts that when luxation of the humerus is complicated with fracture of the surgical neck, art and nature can do almost nothing. But, in 1777, Bottenheit reduced two cases, in which the fracture was as close as possible to the joint; and more recently, M. Baroni (*Gazette des Hôpitaux*, 1841, p. 192) has obtained a similar result on the sixth day. More recently, M. Richet (*Union Médicale*, 1853, p. 499) has reduced a dislocation of the humerus complicated with fracture of the neck of the bone, by pressing with the thumb on the acromion, and pushing the head of the bone outward and upwards with the fingers.

Luxations of the femur may be reduced in the same way as those of the humerus. In 1836, M. Etève had a case of dislocation backwards of the left femur, with fracture of the bone at the middle third, a penetrating wound of the knee-joint, and a fracture of the fibula on the same side. The patient was held firmly by two assistants who placed their hands under the axillæ; two others held a towel surrounding the thigh, between the dislocation and the fracture; while three others held up the limb, so that the thigh was bent almost at a right angle with the pelvis. After making gradual extension, the surgeon pushed with all his strength the head of the femur into the acetabulum, and reduction was instantly accomplished. (*Gazette Médicale*, 1838, p. 751.) Some years before this, Bloxam had reduced, on the eighth day, a dislocation of the femur on the pubes, with fracture above the middle third of the bone, by flexing the limb on the pelvis, and pushing the head of the bone downwards and backwards.

Examples of reduction of dislocation of the ginglymoid joints are more rare. Pézerat (*Journal Complémentaire*, tome iv, p. 276), had a case of dislocation backwards of the radius and ulna, with fracture of both bones two inches above the styloid process. The dislocation was immediately reduced: but by what means is not stated. M. Malgaigne relates a case in which there was dislocation backwards at the elbow-joint, with fracture of both bones at their middle. M. Malgaigne chloroformed the patient, and readily pushed the bones into their place. The fracture was treated; and the patient nearly recovered the perfect use of the arm.

One case only of reduction of dislocation of the knee, with fracture, is known to M. Malgaigne. In 1850, a woman came under the care of M. Jules Guérin (*Arch. Gén. de Méd.*, October 1852, p. 152) with dislocation outwards of the left knee, and fracture of both bones of the leg at the middle. Slight extension was employed: and the luxation was reduced by rotating the leg from without inward.

Delamotte relates a case of dislocation of the foot with fracture of the leg three finger-breadths above the joint. He applied extension and counter-extension; and pushed back the dislocated bone with the palm of the hand. That the extension here, as in other cases, was not of much value, M. Malgaigne thinks proved by the fact, that Delamotte succeeded without it in reducing dislocation in an analogous case. M. Corbin, in 1843, communicated a similar case to the Academy of Medicine. Delamotte (*Chirurgie*, 1845) and M. Robert (*Journal de Chirurgie*, 1845) have reduced dislocations of the lower jaw, complicated with fracture.

In operating on these cases, M. Malgaigne recommends that chloroform should be used; that the fractured limb should be held by assistants; and that it should even be temporarily put up in an apparatus before the reduction of the dislocation is attempted. Gentle motion of the joint should be practised at an early period.

In dislocations of older standing, Boyer, Sir A. Cooper, and Dupuytren, discountenance attempts at reduction. In 1828, however, Warren reduced a dislocated humerus, where the bone had been fractured, at the end of seven weeks. In 1846, M.

Malgaigne met with a case of fracture of the radius, with dislocation backwards of the elbow. He did not discover the latter accident until the seventeenth day; and when he then tried to push the bones into place he failed. He therefore waited until the fracture was united; and, on the thirty-eighth day, reduced the dislocation by extension and sudden flexion.

He also relates a case of dislocation of the radius with fracture of the fore-arm. Reduction of the dislocation was attempted after the union of the fracture: it was unsuccessful, but the power of motion was improved.

M. Malgaigne concludes his essay by referring to cases in which a false socket has been formed; and in some of which, MM. Ribéri, Peyrani, and others, have successfully attempted, by perseverance in passive motion, to give to the limb a considerable power of movement.

specially relieve the viscera within, or any one of them more than another.

The author introduces the accompanying sketches to illustrate his views.

We shall assume the anatomical details to be correct (the author being a lecturer on anatomy), referring to the original paper any of our readers who may not be satisfied on this point.

The author assumes two points as the foundation of his argument. 1, that the relief in local blood-letting is through the blood-vessels, or vascular system; and 2, that there can be no special relief from local blood-letting, unless the blood-vessels of the affected part communicate with those of the part from which the blood is drawn.

He shows that the arteries of the walls (which are accompanied by corresponding veins) are derived from branches of the subclavian, axillary, external and internal iliac, and common femoral arteries, and from the lumbar and thoracic intercostal arteries, which arise from the back part of the aorta, whilst the visceral arteries spring from its front and sides; that the visceral arteries form no communications with the parietal arteries; and consequently that blood taken from the latter cannot relieve the viscera, except by diminishing the volume within the parent trunk, the blood-letting thus losing its local character and becoming general.

The author notices one exception to this, in the anastomosis along the rectum between the vessels of the great intestine and those of the perineum. This has led to the French practice of leeching the perineum to relieve the abdominal viscera, but this practice has not met with much favour in this country.

He also shows that the reflections of the serous membranes, as they connect at certain places the viscera to the walls, cannot be regarded as establishing a medium through which the blood-vessels of the viscera can be relieved.

Having shown that there can be no direct relief or *draining* of blood to the viscera from the walls, he next proceeds to point out that neither can there be relief on the principle of derivation, or *counter-draining*, as he terms it. The arteries of the wall arise at too great a distance from those of the viscera, or, in the case of the intercostal and lumbar arteries, have the great current of the aorta interposed between the orifices of the vessels; and the author accordingly concludes that "it must therefore be held, that the abstraction of blood from the wall of the abdomen or chest cannot act in any way or according to any principle, as far as specially influencing the contained viscera is concerned, in any other light than as a general blood-letting."

After a survey of the blood-vessels of the head, within and without the cranial cavity, the author concludes that the brain is not to be reckoned as one of the internal viscera beyond the reach of local blood-letting, as the veins of the scalp communicate by the parietal and mastoid veins with the sinuses of the dura mater. He remarks:—

"It would appear, then, from anatomy, that, by leeching the scalp, especially behind the ear, the sinuses of the dura mater and veins of the brain may be relieved, and that as directly, though not so rapidly, as by the method of opening the external jugular vein at the root of the neck.

PRACTICE OF MEDICINE AND PATHOLOGY.

ANATOMICAL CONSIDERATIONS ON THE MODE OF ACTION OF LOCAL BLOOD-LETTING IN AFFECTIONS OF THE INTERNAL VISCERA.

In the *Monthly Journal of Medical Science* for this month, there is a paper by Mr. JOHN STRUTHERS, of Edinburgh, on Local Blood-letting in Affections of the Internal Viscera. The author's object is to show, on anatomical grounds, that local blood-lettings on the chest and abdomen act upon the internal viscera as general blood-lettings, and not locally or specially, as is probably pretty generally supposed. The paper is chiefly an anatomical one, showing, after a careful and comprehensive survey of the blood-vessels which supply the viscera and the walls, that there is no connexion between them, and that therefore blood taken from the walls of the chest or abdomen cannot

Fig. 1.

Fig. 1. Longitudinal plan of the arteries of the trunk. The left side shows both the longitudinal and transverse anastomosing arteries of the wall; the right side only the longitudinal and diaphragmatic anastomoses belonging to the wall, and the various visceral arteries springing from the aorta.

Left Side. 1, internal mammary; and 2, deep epigastric; connected behind to aorta by series of intercostal, lumbar, and diaphragmatic arteries; 3, superficial epigastric; 4, circumflex iliac; 5, ilio-lumbar from internal iliac.

Right Side. Branches of abdominal aorta, from above downwards, diaphragmatic, celiac axis, superior mesenteric, right supra-renal and renal, right spermatic or ovarian, and inferior mesenteric.

Fig. 2. Transverse plan of the arteries of the abdomen opposite to liver, spleen, and stomach. 1, aorta, giving off from its back part the arteries (2, 3) for the wall, which unite in front with branches of the internal mammary arteries (3, 3). 4, celiac axis, coming from front of aorta, and supplying spleen, stomach, and liver, the latter also receiving the vena porta.

Fig. 3. The same, lower down, showing portion of small intestine and sections of ascending and descending colon and of kidneys. 1, aorta, giving off behind the lumbar arteries (2, 3), which join in front with branches of the deep epigastric (3, 3). In front, as if coming from the aorta at the same part, are shown the superior and inferior mesenteric, and at the sides the renal arteries. Fig. 1 shows the order in which these visceral arteries come off at different stages of the aorta, and their relative size.

The anatomist will notice, that it is chiefly the anastomosing branches of the arteries of the wall which are shown, and also that these are represented proportionally larger than natural.

"The common practice of cupping on the back of the neck, with the view of specially relieving the brain or head, is no doubt generally, or in great part, efficacious, simply as a slow or mild general blood-letting; but is at the same time not without anatomical recommendation as a local blood-letting. The mastoid communication from the lateral sinuses is to the occipital veins, and these communicate freely with the veins of the back of the neck; and also the arterial supply to the back of the neck, derived from the deep cervical and occipital arteries, has free communications with the posterior muscular twigs, which the vertebral arteries give off during their ascent to the brain."

Like most of our brethren in the north, who have seen

who revere the names of Monro, Abercrombie, Kelly, and John Reid, Mr. Struthers is one of those who "cannot understand how the quantity of fluid within the cranium can vary, until it can be proved that the brain can be compressed, *i. e.*, diminished in bulk, by any force that the heart is capable of exerting". But to this disputed question in physiology he merely alludes for the purpose of protesting against the idea of some, that it should be allowed to alter or influence our practice in cerebral affections; remarking that, "whichever view be correct, we have still the same principles to contend with in practice; we have in both increased or diminished *pressure*, and in both increased or diminished *rapidity* of the circulation; and it therefore appears to me that those are in error who suppose that this question should influence our practice or our reasoning thereon".

Having drawn the above conclusions as an anatomist, Mr. Struthers next comes, as a practical man, to inquire whether these considerations should lead us to abandon local blood-letting in affections of the viscera. It will be satisfactory to those who have long used the leech and cupping-glass, in the faith of their special efficacy, to "learn that the prudent and proper practice still is to apply the treatment over the affected part. This is because we cannot be sure of the exact situation and limits of the disease. There is pain as if in the liver. Is the affection one of the liver itself, or of one of the serous layers of the diaphragm, or of the parietal peritoneum? There is pain as if in the kidney. Is it in the kidney, or in some part of the wall, or in both? We cannot be sure, and therefore we must treat the affection as a regional one—as an affection of, or in, the right hypochondriac region in the one case, and of the lumbar region in the other. If the viscus alone be affected, the blood drawn from over it will at least relieve it *as much* as a similar quantity taken from some other part would do; and, if the wall also should be affected, or be the entire seat of the disease, the patient, without running the risk of missing a better practice, has had the benefit of the doubt.

"The same remarks apply to the chest. Local blood-letting must have the same direct effect in pleuritis that it has in peritonitis; the membrane in either case forming part of the wall: and can the practitioner be sure that the parietal pleura is not involved as well as the lung? The pericardium, again, receives part of its vascular supply from the internal mammary arteries; and it is therefore in our power to derivate from this part by leeching the front of the chest.

"We must therefore come to the conclusion, that, in treating affections of the viscera of the abdomen and chest, it is best to take the blood from over the painful or affected part; grounding the localisation of our practice, not on the vague belief that we can thereby specially relieve the viscus, but on the uncertainty of diagnosis, which leaves us unable to say whether the wall also is affected or not."

The only alteration in practice which such considerations would warrant, would be in those cases in which it is the object of the practitioner simply to lessen the quantity of blood in a congested or over-active viscus, or where he feels assured that the affection is *limited to the organ*; and in such cases the author remarks, "it would appear that it matters not where or how he bleeds; according to circumstances, he may take his choice both of the part and the mode, feeling assured that, from whatever part he takes the blood, whether by the leech, the cupping-glass, or the lancet, he will reach the affected organ only by having withdrawn so much blood from the general circulation".

It is but seldom, however, that such cases occur in ordinary practice. Whilst we frequently know the parietal pleura or peritoneum to be affected as well as the viscus, we never can be quite certain that they are not so, even in these days of physical diagnosis and clairvoyance; and as the same quantity of blood taken from over the organ will do at least *as much* good as a similar quantity taken elsewhere, whilst the rule is simple as a guide to the practitioner, besides being more likely to ensure the confidence of the patient,—the author very properly recommends the continuance of the present practice of drawing the blood from over the affected or painful part.

The object of this paper, then, is not to alter our practice, but to explain the mode in which our local blood-lettings are serviceable in affections of the abdomen and chest. Mr. Struthers shows that local blood-lettings relieve the stomach, intestines, liver, spleen, kidneys, heart, and lungs, only as general blood-lettings to the same extent would do; and that the superiority of local over general depletion (which all experience goes to establish) is due to the local relief afforded to the wall, which is usually in part, and sometimes in whole, the seat of the affection.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

JAMES COPLAND, M.D., President, in the Chair.

SCIRRHUS OF THE PROSTATE GLAND, ALSO OF THE LUMBAR AND PELVIC LYMPHATIC GLANDS. BY JOHN ADAMS, ESQ.

CASE. A gentleman, aged 59, was suddenly seized with paralytic symptoms, which seemed to arise from derangement of the circulation. During his recovery he experienced frequent desire to pass urine, and required the constant use of the catheter. The instrument passed over a hard and rough surface, and induration and enlargement of the prostate were felt on examination *per rectum*. Pains about the pelvis ensued; the saphena vein became thickened; the thighs were drawn up upon the trunk; and he died three years after the appearance of the first symptoms. There had been no hæmorrhage.

EXAMINATION OF THE BODY. The lumbar glands, and the lymphatic glands of the pelvis, were enlarged by the deposition of scirrhus. There were cysts containing pus near the symphysis pubis. The prostate gland was enlarged to nearly twice its natural size; an ovoid mass, distinctly scirrhus, the size of a small nut, projected into the bladder from its upper surface. The left lobe was occupied by a long scirrhus mass; the right lobe appeared healthy. The left vesicula seminalis was diminished in size; and the prostatic plexus of veins contained phlebolites. The left kidney was enlarged and contained much sabulous matter. The tumour was examined microscopically, and found to be true scirrhus.

In the discussion which followed, in which Messrs. BOWMAN, CHARLES HAWKINS, and HOLMES COOTE took part, the rarity of the occurrence of genuine scirrhus in the prostate gland was noticed: while fungous disease of that body was not uncommon. The absence of hæmorrhage was ascribed to the mucous membrane being free from abrasion.

TREATMENT OF STRICTURE OF THE URETHRA BY EXTERNAL INCISION. BY JAMES SYME, ESQ., F.R.S.E.

Mr. SYME commenced by apologizing for venturing to lay his observations before the practitioners of London. The comparatively small field which it had been his province to occupy might appear hardly to warrant such a course. It might also be said that he might have availed himself of the ordinary channels, instead of reading a paper to the Royal Medical and Chirurgical Society. But he would plead as his justification the peculiar circumstances in which he felt himself placed, and his sincere persuasion that he had devised an easy, safe, and effectual mode of relief from one of the most distressing infirmities we are acquainted with. He was desirous that this benefit should be extended; but, as the reception of his proposal had been impeded by the statements which had emanated from metropolitan publications, he believed that, although the truth might and no doubt ultimately would prevail, a long time, must elapse before it could be embraced through the ordinary course of experience. And any attempt to unravel or refute the various statements which had been made concerning the operation, by tracing out their errors, would have been a task no less unpleasant than unprofitable. Under those circumstances, it had seemed to him that the only practical mode of conduct was to come personally before that society, which, more especially, was understood to represent the respectability and intelligence of the practitioners in London; to explain the plan of treatment which he had endeavoured to introduce; and to state the facts upon which he was willing that its credit should rest, and supply any further information which might be required by any member of the society who had entertained a different opinion upon the subject.

It would be unnecessary to detain the society by an account of stricture; the object being to direct attention to certain forms of the disease, which resist the hitherto established means of treatment, and which seem to require some other remedy. In one of these forms of stricture there is extreme irritability, and attempts to effect dilatation are followed often by violent local and constitutional disturbance. In another, the stricture might be dilated, but speedily contracted again, so as to renew the

* The proceedings of this meeting were taken in short-hand, expressly for this Journal, by Mr. G. Cole.

symptoms attending the first stricture; and in the third form the stricture might be dilated sufficiently to admit the insertion of a full-sized instrument, but micturition remained painful, difficult, and uncertain. For the remedy of these three forms of stricture, there were various established means of treatment which might be referred to two heads—dilatation and the use of caustic; these have proved unavailing beyond a temporary amelioration, and have too frequently aggravated the evil. He would not calculate how many lives had been rendered miserable through the vain struggles on the part of surgeons to remedy the disease, but he would simply notice the will of M. Argenteuil, who bequeathed funds sufficient for bestowing periodically a prize of £500 for the greatest practical improvement in the treatment of stricture.

The simple bougie was quite sufficient for the treatment of ordinary strictures; but for the effectual remedy of stricture when it assumed one or other of the peculiar forms to which attention had been directed, he maintained that a free division of the contracted part of the urethra was essentially required. For this purpose, he introduced a grooved director; and he believed that there was no stricture which, through time and care, might not be made to admit an instrument of this kind. The patient being then placed upon his back at the edge of the bed, and the knees held up, an incision of about an inch and a half in length was made in the perineum, sufficient to admit the knife, while the thick texture was freely divided to the extent of an inch or two, or more if necessary. A No. 8 catheter was afterwards retained in the bladder for at least two, but not more than three days. The procedure which was described was extremely simple, and might be accomplished in a very short time. At the same time, no operation demanded a more exact precision of performance, whether regard were had to the attainment of its object or to its immediate effects. Unless the urethra were divided at the proper place, no permanent benefit could result. If the knife were not confined to the middle line of the perineum, there would be the greatest risk of hæmorrhage and extravasation of urine. M. Reybard, who appeared to follow the plan of internal incision, had said that whatever were the form of the stricture, the incision ought always to be directed laterally, so as to avoid the artery of the bulb placed below. But the Academy of Medicine, with regard to the position of the artery of the bulb, had promulgated a great error in the practice of surgery; since the vessel lay at the side of the canal, and could be avoided with certainty only when the incision was made exactly in the middle line. Mr. Syme had heard that in one of the London hospitals the operation had been performed, professedly according to his principles, without any grooved conductor, the only guide being a small silver catheter. He believed it not possible to make a straight, continuous incision through the stricture on such an instrument. He had read of a case in which a catheter, instead of being retained for two, or at most three, days, had been left in for six weeks, notwithstanding the well-established fact, that the presence of such an instrument, so far from promoting, greatly impeded the closure of the fistulous opening into the urethra. With still greater astonishment, he had heard of operations, performed in London and Paris, considered to be in accordance with his principles, but without any instruments at all being introduced through the stricture. For the disastrous results of such proceedings, the operation which he had proposed could not be held responsible. The only sources of danger were hæmorrhage and extravasation of urine. When the knife was properly applied, there could be no bleeding, except from the superficial perineal vessels, and the cells of the corpus spongiosum. There was seldom more than a teaspoonful of blood; and with oozing it hardly amounted to one or two ounces. If the patient were full of blood, the quantity discharged in the regular way might be allowed to go on to the amount of a teaspoonful. This would prove rather salutary than otherwise; and was hardly to be prevented, except the patient were in a nervous state from unnecessary alarm; and this small amount of bleeding could always be restrained by a piece of lint, applied by slight pressure for a few hours.

With regard to the extravasation of urine, there could be no doubt that the circumstances most favourable to its production were openings through the deep fascia of the perineum. Hence arose the danger of the operation for impermeable stricture by making deep incisions into the perineum. According to his (Mr. Syme's) proposal, only the fascia lying immediately under the perineal integument was incised, and the knife was guided with certainty through the whole stricture. As a further precaution, he retained the bougie until the cut surface was sealed up; so that extravasation of urine was less likely to happen than

hæmorrhage. It was this consideration which had originally led him to regard the operation as free from danger; and, as he had performed it upwards of seventy times, without any fatal or alarming consequences, it would be allowed that his anticipations had not been unduly sanguine.

The following was the course of events which usually followed the operation. The patient having been placed in his bed, on awaking from his chloroform sleep, frequently had considerable difficulty in believing that the operation had been accomplished. He then would begin to feel the blessing of constant relief, no trace of suffering appearing; he was tranquil and easily managed, not requiring opiates, or any other treatment, until there should appear to be a greater degree of oozing from the wound than convenient, on which a piece of lint might be applied until the bleeding ceased, which it usually did in a few minutes. The diet should be chiefly farinaceous, as animal food might cause thirst and restlessness. Cooling drinks, according to the patient's taste, should be supplied; while wine and other stimulants were carefully withheld. At the end of forty-eight hours, Mr. Syme generally removed the catheter; but another day's delay on the whole seemed advisable, because the escape of urine through the wound might thus be prevented. In about one-third of those cases, the instrument had remained only a shorter period. A curious train of nervous symptoms, consisting of rigors, bilious vomiting, suppression of urine, and delirium, sometimes appeared, to the consternation of all those who were unaware of their nature. They occurred most frequently after the catheter was withdrawn; and they appeared to depend upon the urine resuming its natural course. They had never lasted more than thirty hours, and seldom little more than half that time. Opium and other remedies had their disciples; but the symptoms only required for their removal time and patience, so that the surgeon might confidently assure himself that there was no ground whatever for the slightest alarm or uneasiness for the cure. Recovery might be considered complete in the course of a few days, when the patient would pass water in a full stream, with ordinary frequency, having nothing to remind him of the operation, except the superficial appearance of a wound which soon contracted and cicatrised. After the withdrawal of the catheter, the urine continued to escape now and then through the wound, but it soon diminished to a few drops, and gradually resumed its proper course. The cure must be maintained by the introduction of a full-sized bougie every three or four weeks, afterwards at more distant intervals, according to the circumstances of the case.

The author then related some cases illustrative of his treatment; they were first, cases of stricture of the urethra which had resisted the established form of treatment: secondly, stricture of the urethra impermeable by surgeons of experience and reputation, but which might, through time and care, permit the introduction of an instrument, and the free division of the thickened and contracted part of the canal upon a grooved director; so that complete and permanent relief, even in the most distressing and obstinate conditions of the stricture, might be afforded. Each case might not contribute evidence on all those points; but the testimony of the whole must be considered.

CASE I. About twelve years ago, Mr. Syme was directed to take charge of a gentleman suffering severely from stricture, which had been contracted upwards of twenty years. During the greater part of this period, it had admitted of such palliation from the use of a bougie, as not to interfere materially with his comfort; but latterly it had become excessively aggravated. Day and night the calls to make water were almost incessant, and in the laborious effort to empty the bladder the patient was constantly exhausted. He was troubled at the same time with an involuntary discharge of urine. The stricture, which was anterior to the bulb, had contracted so as no longer to permit the introduction of an instrument, and the tall and vast frame of the patient was emaciated to a shadow; and he became so sensitive, that the slightest change of weather greatly aggravated his complaint. In these circumstances, Mr. Syme commenced with introducing a bougie of the smallest size; and when in the progress of the case he had arrived at No. 5, he found the stricture obstinately opposed to any further dilatation. The degree already attained had afforded him no relief whatever. Confinement to bed was then tried, with retention of the catheter, until one of the largest capacity was introduced. The patient's health improved, and he evacuated his water with so much more ease, that Mr. Syme expected no more trouble; but the day after the catheter was withdrawn, the symptoms were renewed without any diminution. Soon after this, Mr. Liston having come on a visit to his friends in Edinburgh, Mr. Syme asked him to see this patient; he advised

internal incision with a lanceted catheter. This was accordingly done, so freely, that a full-sized bougie was passed immediately afterwards without the slightest obstruction. As no benefit, however, resulted beyond a partial relief of only one or two days duration, the process was repeated, using two catheters, which cut on two sides, but with no material difference in the effect produced. The patient, who had cheerfully submitted to these long and various efforts to afford relief, now desired Mr. Syme to do something effectual. He suggested the performance of external incision on a grooved director. The patient eagerly caught at this proposal, and from that time, more than ten years, has enjoyed the most perfect local and general health.

CASE II. In 1844, Dr. Wickham of Penrith came to Edinburgh with a case of stricture, which had proved peculiarly obstinate and distressing. Although the patient was under 50, it had existed for twenty-seven years. Latterly, the symptoms having been much more severe, the assistance of a practitioner had been required; but the patient returned home after two months assiduous attempts without ever getting an instrument introduced. There was now a fistula; and such stony hardness as to suggest cartilage. Upon examination, a full-sized instrument could be passed without pain or bleeding. The patient returned home; but in the course of a few months came back with the symptoms of stricture no less urgent than before. Mr. Syme introduced a grooved director into the contracted part, and freely divided it by internal incision; the patient soon felt quite well. More than eight years have elapsed, and he still remains well.

CASE III. A gentleman, aged 80, came from Sunderland to put himself under Mr. Syme's care, on account of a stricture in the urethra. After many abortive efforts, the patient, despairing of relief, resolved to endure the complaint without any attempt at a remedy. Symptoms of frequent incontinence added to difficulty of evacuation set in, and he placed himself under Mr. Syme's charge. At the end of six weeks he returned home in the enjoyment of perfect health; and Mr. Syme had heard recently that he continued to do so.

CASE IV. —, aged 35, married, of correct habits in his mode of life, applied to Mr. Syme in the month of October, with a stricture anterior to the bulb. For the last five years he had been under the treatment successively of three most eminent surgeons in London, who had employed dilatation by bougies with the effect of affording partial relief, but neither complete nor permanent. A director having been passed, an incision was made in the middle line of the perineum, and pushed the knife forwards so as to divide the stricture completely. A No. 8 catheter was passed with perfect facility, and retained in the bladder for forty-eight hours. The nervous state to which reference had been made as a not infrequent occurrence, commenced and continued about the usual period so as to alarm the patient and his friends. To the patient's great comfort, urine flowed copiously in a full stream, very different from that to which he had been so long accustomed; and recovery was in every respect complete.

CASE V. Captain — applied to Mr. Syme in January 1851, on account of a stricture, of which he gave the following history. "In 1829 I was serving on board one of Her Majesty's ships in the Mediterranean when I first observed the stricture. Bougies were then introduced; and in a short time the complaint seemed to be overcome. I continued until 1832 in the East Indies, on board one of Her Majesty's ships, and I suffered very much. I sought relief on board ship, but found none, as the medical man could not pass an instrument. This state of things continued for two years, no instrument having been passed. In 1836 I sailed as Lieutenant in a ship for the Arctic regions, when I suffered great inconvenience in making water. I was there when the ice broke up, exposing the ship to great danger, and obliging the officers, as well as men, to expose themselves to a very low temperature—80° below freezing point upon some occasions. At the end of the voyage, I went to Haslar hospital, where I remained for six weeks. I then went to an eminent surgeon, who succeeded in passing bougies up to No. 6. He then used a catheter with a lancet blade with little benefit. I suffered severely when on the coast of Africa; and on two occasions I felt it necessary to decline offers of appointments in the service."

Upon examination, Mr. Syme found a slight contraction, about three inches from the orifice, anterior to the bulb. He passed bougies up to No. 4, but further dilatation was resisted; and as the patient had experienced no relief from the degree afforded, he divided the contracted part by external incision. After the usual symptoms, he made an excellent recovery, and continues well.

CASE VI. Mr. —, aged 27, from his earliest recollection, had experienced a degree of difficulty in evacuating his urine. In 1843, he went to the East Indies, and there suffered severely from attacks of gonorrhoea. Having returned home, he was exposed to severe cold in Ireland. Next year, a fresh attack of gonorrhoea was followed by aggravated symptoms of stricture, which led to the employment of various measures without success. Being in the public service, he went to Haslar Hospital at Portsmouth, where innumerable attempts were made with all sorts of rigid and flexible instruments; but all in vain. The stricture was in the usual situation, anterior to the bulb. The patient came to Edinburgh; and, at the very first attempt, Mr. Syme passed a metallic bougie. At the end of three weeks, he could introduce a No. 10 instrument. The patient then went home, with instructions to have the instrument passed regularly. Twelve months afterwards, he again applied, complaining that the stricture was as troublesome as ever. Mr. Syme passed small bougies on two different occasions; but as severe rigors were produced, and the symptoms derived no alleviation, he performed the operation. Nothing occurred to impede recovery, and at the end of three weeks the patient returned to London, being able to make water with a degree of freedom he had never known. Wishing to know the present state of this gentleman, Mr. Syme had written to Mr. Henry Thompson, and had been informed by him that the patient had had no return of his old urinary symptoms.

Six other cases were related by Mr. Syme, which, however, we are from want of space compelled to omit.

The cases were selected from Mr. Syme's private practice, as permitting more easy and satisfactory reference. Hospital patients were often lost sight of when they left the hospital. He presumed not to throw blame on his brethren for the employment of other means; but these means were not always sufficient. The operation might be performed with safety; and he ventured to hope that the Society would give him the credit of good intention in bringing the matter under its notice. (Applause.)

Mr. WADE said, that it was well known that surgeons had, previously to Mr. Syme, directed their minds to the performance of the perineal section in intractable cases in which no instrument could be passed; though they had never thought of performing it to the extent recommended by him. There would be differences as to the best mode of managing the more intractable strictures. It probably mattered little to the patient what means were adopted, so that the object was gained without danger: but where there was danger in any proceeding, it was the duty of the surgeon first to employ every other means. The operation was not new; for Sir B. Brodie, in the edition of his work on *Diseases of the Urinary Organs*, published in 1841, in speaking of the difficulty of dilating urethral obstruction, had stated that it would sometimes be necessary to introduce a small grooved staff into the bladder, and divide the cicatrix by an incision through the perineum. Afterwards a gum catheter must be retained for some time. He limited the operation, however, to cases arising from laceration of the urethra.

It was very desirable to ascertain, first, the degree of freedom from danger of this operation; second, the probability of permanent relief which it afforded. In Mr. Syme's hands, the operation appeared to have been remarkably successful; but the results had been so very different in the hands of other surgeons, especially in London, that the subject required a very searching investigation. Perhaps it might all be explained by the more bracing air of Edinburgh. Instead of being a simple means of cure—as it had been represented to be, and no doubt was in the hands of Mr. Syme—it had proved in London nearly, if not quite, as fatal as the operation of lithotomy. The causes of death had been phlebitis and purulent infection; and sometimes alarming hæmorrhage had occurred. Urinary extravasation and abscesses had also been produced. These had occurred too often to be, as had been alleged, the result of accident, and not chargeable to the operation. The patients on whom the operation had been performed had long suffered from intractable strictures; their health was broken; and the parts through which the incision was made had been in a state of long-continued disease: these circumstances, and the condition of hospital patients, might account for the more unfavourable results.

The ultimate effects had certainly not been so satisfactory in London as in Mr. Syme's cases. In the first patient on whom Mr. Fergusson operated by Mr. Syme's method, the stricture returned with nearly its original severity. Not only in London, but in Edinburgh, had there been fatal results; as the case of Dr. Mackenzie in the latter city. In Mr. Miller's case, which

was operated on by Mr. Syme, the patient certainly had a narrow escape with his life. He suffered from abscesses a long time, and was in a very precarious state. Many cases, of the nature of those operated on by Mr. Syme, would be equally restored by a careful use of potassa fusa. With regard to ultimate success, some strictures would recontract, notwithstanding whatever means were employed: and it was not unlikely that contraction would recur in some of Mr. Syme's cases, in two, three, or four years. Sir B. Brodie had stated that, after the performance of this operation for stricture from lacerated urethra, the patient must continue to use a bougie, and must only expect to be able to pass urine by the introduction of a moderate-sized instrument.

Mr. Syme had said that all strictures were tractable in his hands. Mr. Wade would ask how Mr. Syme knows that, in the cases in which he used a small director, the instrument really passed along the natural passage into the bladder? In some cases, the urethra was not only highly contracted, but also almost distorted; and it was very difficult to guide an instrument through such a labyrinth. In cases of entire obliteration of the urethra, with fistulous passage of urine behind the stricture, would Mr. Syme endeavour to force a passage through the obstruction, or have recourse to the old operation for perineal section?

Mr. SOLLY said, that the paper read had appeared to prove the operation to be less dangerous than surgeons were in the habit of considering; but the operation was probably attended with greater danger than Mr. Syme's cases would lead us to suppose. It would be interesting to have the results of Mr. Syme's hospital practice, and to know in what cases he considered the operation necessary. He (Mr. Solly) believed that, as a rule, the bougie alone was sufficient, if patience were exercised. By beginning with a small catgut bougie, and gradually increasing the size, there was scarcely any stricture which might not be overcome. The plan of Mr. Wakley, of passing a small instrument through a larger one, was worthy of attention. Mr. Solly had employed it with advantage. As far as his experience went, when once an instrument could be introduced, division was unnecessary. There were no doubt cases of irritable stricture, in which the perineal operation might be necessary; and in those cases—of the existence of which every London surgeon must be aware—in which the stricture was absolutely impermeable, the operation would be both necessary and advantageous. At the same time, other operations had been performed, as puncturing the urethra posterior to the stricture. He feared that the junior members of the profession would think the operation universally successful, and have recourse to it on insufficient grounds.

Mr. COULSON hoped that we should be able to determine to what class of cases Mr. Syme's operation was proper. The external division of stricture had been recommended in 1811 by Mr. Chevallier; but he confined this practice to cases complicated with perineal fistula, chiefly to those produced by external violence. In 1822, Mr. Arnott read a paper before the Society, advocating the division of stricture from without: he recommended it, not as the means of removing retention of urine, but of curing stricture before it became unmanageable; but only when no reasonable hope of cure from caustic could be expected. In the following year, the late Mr. Shaw recommended that the operation should be had recourse to before the tissues had become so indurated as to render the operation almost useless. It was undeniable that certain forms of stricture resisted all ordinary modes of treatment. Were these to be abandoned to their fate, or were there effectual means of relief? He would not hesitate to have recourse to the plan of Mr. Syme in such instances.

There were three classes of cases in which Mr. Syme's operation was applicable. The first class consisted of those in which the urethra was all but obliterated by chronic inflammation of the mucous and submucous tissues. In the second class, not only was the urethra involved, but the submucous and spongy tissues were converted into a hard fibrous mass. These could not be cured by ordinary means. The third class of cases consisted of those in which there was fibro-elastic tissue, more like India-rubber, where the stricture easily yielded, but immediately returned. Temporary relief might be obtained, but not permanent cure. Attempts at dilatation were followed by severe constitutional irritation, very often by retention of urine.

Much had been said about the severity of the operation. Mr. Coulson had performed it as often as any other surgeon in London. One of his earliest cases had been fatal, from purulent infection; another had nearly died from hæmorrhage. Hæmorrhage he believed to be the only danger to which the operation was exposed; and, if carefully dealt with, this need

not be feared. There might be some little difficulty in introducing the catheter after the operation into the posterior portion of the urethra. To obviate this, he had introduced the director along a small grooved tube, before withdrawing it.

Mr. T. WAKLEY, as a visitor for the evening, was anxious to make a few remarks. They had heard of a family of Blanques treated by Messrs. Blaque, eminent London surgeons. Now, as the results of the operation had been so different in London and in Edinburgh, he thought that a searching inquiry was called for into the circumstances of the cases, and that to enable this to be accomplished, Mr. Syme ought to have stated the names of some of his patients and of all the surgeons to whom he had referred. (Order, order.)

The PRESIDENT stated that the names had been furnished: but he had not judged it proper to allow the usual practice to be departed from by giving names publicly in the society. Surgeons referred to by name in that way in their absence might with justice complain. It would be unusual and improper.

Mr. P. HEWITT said that such a course as that proposed by Mr. Wakley never had been allowed in that society. (Hear.)

Mr. T. WAKLEY: I will, then, ask Mr. Syme if he sent a challenge to the London surgeons — (Order, order.)

The PRESIDENT having again interposed, Mr. Wakley sat down, after remarking that he saw clearly that he was not likely to get a fair hearing.

Mr. HENRY SMITH had seen five cases of perineal section, in which the operation had been skillfully performed. One of them was the case referred to by Mr. Coulson, in which the patient nearly died of hæmorrhage. With reference to contraction of the urethra after the operation; he (Mr. Smith) had last week seen a naval officer, on whom he had assisted in performing the perineal section in November 1848. No bad symptoms followed, and the patient went to sea; and when again seen by Mr. Smith, in September 1851, he stated that "he was nearly as bad as when the operation was performed. He had passed an instrument for a year, remaining perfectly well; but had afterwards neglected it, and the stricture had returned. Only a No. 3 bougie could be passed. Last week, only a No. 4 instrument would enter, and there was much difficulty in passing urine. He had seen two fatal cases.

Mr. GAY thought that the discrepancy between the results of Mr. Syme's operations and those of English surgeons might be accounted for by considering the different conditions of the patients. Mr. Syme's patients were in a better class of society, and more able to bear operation than those of English surgeons, who had been mostly hospital patients, in whom hæmorrhage, inflammation, and all the mishaps of operation were more likely to take place. A more accurate judgment of the value of the operation would be formed from an account of Mr. Syme's hospital cases. It was not necessary that an operation should be always successful to render it a good one, and the occasional fatal results should not lead us to reject the operation in suitable cases. He would also ask in what cases Mr. Syme would not perform the operation, as well as those in which he would do so. Mr. Syme had referred to a case which had been under his (Mr. Gay's) care. The operation had in that case been eminently successful: and he thought it his duty to bear this testimony. He trusted that in future all acrimony would be banished from discussions of this subject.

Mr. SYME begged to express his grateful sense of the kindness with which his communication had been received, and also the extreme satisfaction he had felt from the tone and temper in which the subject had been discussed. It was peculiarly gratifying to him that the gentlemen who had devoted so much attention to the treatment of urethral diseases, as Mr. Coulson and Mr. Gay, should express sentiments so favourable to his proposal. He certainly participated in the wish of the latter gentleman, that for the future the treatment of stricture by external incision should be discussed solely with reference to its own merits, and entirely free from personal considerations. For his own part, he had always been desirous to avoid saying anything personally offensive, and he was not aware of having ever done so. But if a single word or expression could be pointed out to him as admitting of such a construction, he would be most willing, and, indeed, anxious, to withdraw it. He hoped the Society would no longer regard the operation he had proposed as a formidable gash of the perineum, rivalling the wound of lithotomy, and exposing the patient to danger from hæmorrhage as well as extravasation; but, on the contrary, clearly understand that it was an incision always anterior to the bulb, and, therefore, implicating a very inconsiderable thickness of parts, which might be cut with perfect safety. The valuable results of the operation in London were rather

EDITOR'S LETTER BOX.

THE VACCINATION BILL.

LETTER FROM DR. SEATON TO THE EDITOR.

subject for him to enter upon, as he could not avoid attributing them to a want of due attention to the points which he had endeavoured to inculcate for safety and success. If the contraction were not fairly divided, there would be risk of extravasation, even with the protection of a catheter; and if the knife were allowed to glide past the conductor, it might readily cut the artery of the bulb; in which case plugging the wound would become requisite, with a great risk of extravasation. In short, he believed that the operation, if correctly performed, was perfectly safe, but, through a very slight deviation, might place the patient in the greatest danger. But if he had been correctly informed that, in one of the London hospitals, a small silver catheter had been used as a guide, instead of a grooved director, he could not be surprised at the results not being satisfactory.

As to the case operated upon by himself in Edinburgh, and published by Professor Miller as an escape from extreme danger, he believed that the nervous symptoms described in his paper had imposed upon Mr. Miller; who, so far as he knew, had had no further experience of the practice than this single instance which he had witnessed as the family attendant. He did not believe that there had been the slightest ground for serious apprehensions in this case; and as the patient, after being for a year under this treatment by Mr. Liston without relief, had been restored to perfect health by the operation, he thought that, instead of being quoted as an objection to its practice, it should rather be regarded as a very favourable example of success. With regard to the results of his hospital experience, he could assure the Society that they had been in no wise inferior to those he had preferred relating from private practice, on account of the greater facility of reference. He could also assure the gentleman who put the question as to the proportion of cases treated in his practice by dilatation and incision, that the latter bear a very small ratio to the former, in confirmation of which fact he might appeal to one of his colleagues in the Royal Infirmary, Dr. Mackenzie, who was present. As to the treatment of obliterated urethra, when this canal was truly closed through part of its extent, the operation for stricture was not applicable; all that he contended for being, that where the water got out a bougie might be got in. The only case of stricture which he should think beyond the reach of benefit from this operation were those where organic disease existed in some other part of the urinary organs. It was well known that the presence of a stone in the bladder prevented the successful treatment of stricture; and it was therefore reasonable to expect that chronic irritation in the kidneys, or elsewhere, might produce a similar effect. In conclusion, he begged to express his hope that the unmeaning title of "Perineal Section," which had originated with the opponents of the operation, would be banished from surgery. He had no objection to the terms "urethrotomy" or "operation by external incision".

CREWKERNE AND YEOVIL DISTRICT MEDICAL ASSOCIATION.

The FIFTH GENERAL MEETING of the Crewkerne and Yeovil District Medical Association was held at Crewkerne, on the 14th instant. The general business was transacted, and the finances shown to be in a flourishing condition.

VACCINATION BILL.

The Vaccination Bill was discussed, and its principle as a whole approved; the members deeming compulsory vaccination desirable. It was considered, that if the fee payable to the public vaccinator were raised to a minimum of half a crown for each successful case, the operation would be more satisfactorily performed and more generally extended; and that it would be a more fair remuneration for the time and trouble required in country districts, where the vaccinator has to make a house-to-house visitation in order to see the cases. It was also considered that the registrar would not be sufficiently paid by the fee of one penny for each notice. There was some complaint of the impropriety of the public vaccinator being compelled to vaccinate the children of respectable persons (not being his own patients) gratuitously.

ILLEGAL PRACTICE.

The members of the Association were requested to report to the Honorary Secretary any cases of illegal practice which might come under their notice, as the Society is about to take proceedings under the Apothecaries' Act, in order to check the increasing evil of prescribing by unlicensed persons.

ELECTION OF OFFICERS.

The late officers were re-elected; Dr. Tomkins, of Yeovil, as President, and Mr. G. F. Wills, of Crewkerne, as Honorary Secretary.

SIR,—As it appears from the leading article in your Journal of the 22nd instant, that you have not been correctly informed as to the proceedings of the Small-pox and Vaccination Committee of the Epidemiological Society, with regard to the Vaccination Extension Act now before Parliament, I am requested, on the part of the Committee, to explain that their exertions have not, as you suppose, "been limited to endeavours to improve Lord Lyttelton's measure", but they *have* been used, and mainly used, for the purpose of retarding the Bill till the Report which they were preparing should have appeared and have been discussed by the medical profession.

It was, indeed, in consequence of the representations made by the Committee, as soon as they became cognizant of a Bill on the subject having been introduced into Parliament at all, that the second reading of that measure, *which otherwise would have taken place on the 14th March*, was postponed until the 5th April; and although the Bill, with various amendments, has subsequently gone through all its stages in the House of Lords, without any further application for delay on the part of the Committee, it has been with the understanding throughout, that no step would be taken in the House of Commons till after the publication of their report. The course adopted by the Committee, of not requesting any further postponement in the House of Lords, appeared to them the right one to pursue: first, because the principle of the measure (that of making vaccination compulsory), and the question of medical remuneration were, both of them, subjects which it seemed more particularly the province of the House of Commons to discuss; and, secondly, because, unless the Bill had reached the Lower House at this period of the session, there was little chance (from the multiplicity of business with which that House is oppressed later in the year) that it would have received the attention and discussion, which the importance and, I will add, the urgency of the subject demand; for the Committee, looking at the results of the present system in this country, as exhibited in their Report, do not by any means deem it an unimportant matter whether an effort be made at once to correct them, or whether this be postponed even for a single session. It is sufficient to state, that there are in England and Wales nearly 8,000 deaths a-year from small-pox, in the immense majority of which there has neither been vaccination, nor attempt at vaccination, to show that the view which the Committee take is not an exaggerated one.

The Report is now ready to be submitted to the judgment of the profession, and the Committee are rejoiced to bring it before the Provincial Medical Association, of whose former labours in the cause of vaccination they entertain the highest appreciation, and from whose Report they have, in many parts of their inquiry, derived the greatest assistance and instruction. They anxiously await the verdict that shall be passed upon this first result of their labours. But if any notion should have got abroad that it is a document hastily got up, I have only to assure you that it is a most careful digest, much of it prepared months ago, of information derived from authoritative sources at home and abroad, and from correspondence with upwards of two thousand of our medical brethren; that it was submitted in due form to the Council of the Society, and approved by them; and that afterwards, by their desire, a copy was transmitted to the Home Secretary. And I have further to state, that in the personal communications which the Committee have had with members of the government, or with Lord Lyttelton, they have never pretended to be other than a committee of scientific inquiry; they have not wished nor presumed, on any occasion, to put themselves forward as the political representatives of the medical profession, nor as arbitrators between the profession and the legislature.

In conclusion, while the Committee are not responsible in any way, as will have been seen by this statement, either for the original, or for the amended bill of Lord Lyttelton. While, indeed, they consider even that the latter is, in many respects, highly objectionable, they concur entirely with his Lordship in the necessity for an act to make Vaccination compulsory; and they deem it but due to him to state, that he has invariably represented this, *and this alone*, as the principle on which he meant to take his stand, and has always expressed his readiness

to adopt any suggestion which should not endanger the acknowledgment of that principle by the legislature.

I am, etc.,
EDWARD C. SEATON, M.D.,
Hon. Sec. to the Committee.

33, Sloane Street, April 26th, 1853.

[The doctrine of extreme urgency—the idea that a Bill must at all hazards be passed during the present session,—appeared to have taken possession of the Epidemiological Society. It was this doctrine that we formerly protested against, and now again protest against, on behalf of the medical profession. The Epidemiological Society would, we fear, be contented to make Lord Lyttelton's Bill a tolerable measure, while we would rather set it aside in the meantime, and struggle for enlightened legislation next session on the whole subject of Small-pox and Vaccination. EDITOR.]

PROBABLE EFFECTS OF THE VACCINATION BILL.

LETTER FROM J. A. HINGESTON, Esq., TO THE EDITOR.

SIR,—If Lord Lyttelton's Vaccination Bill should be passed into an Act in its present printed form, there can be little doubt that one of the effects of its operation would be to throw the practice of vaccination into the hands of the most needy—the lowest, and, therefore, the least estimable members of the medical profession. It is not likely that the legally appointed officer would be any other than a youngster, a novice, or some one who, from infirmity of mind or body, or some other less excusable reason, might be unable to obtain the favour and confidence of the public in private practice. Although the nominal fee or reward would, in most instances, be superseded by the gratuitous generosity of the better classes of society, yet it would be unpleasant to any right minded practitioner to receive what he could not legitimately demand, while it would not be long before the mass of the community would agree in withholding that which, according to law, they were not required to bestow. The usages of the world quickly conform themselves to the order of the day; and the performance of medical services would not fail, in a very short time, to be called for and insisted upon, as in this case enacted, without fee or reward. The result would be, apathy on the side of the medical practitioners, and petty exaction on that of the public. In the end, the best practitioners would relinquish vaccination altogether, and refer the care of it entirely to the medical officer appointed according to the provisions of the act. Thus, one of the most interesting points of pathology ever yet broached would be abandoned, and passed over to the caprice and zeal of such individuals as might have the leisure to prosecute the study of it, for their own satisfaction or amusement.

At present, the failure of vaccine lymph is acknowledged, and the chief object ought to be that of ensuring a fresh supply of it in its genuine form. In default of this supply, Lord Lyttelton's compulsory bill runs the risk of becoming nugatory, fallacious, and ridiculous.

His lordship lays much too great a stress on the authority of the Epidemiological Society—"A new society," says his lordship, (House of Lords, Tuesday, April 12th.) "of which Sir B. Brodie, Dr. Babington, Dr. Southwood Smith, Dr. Bright, and other eminent medical men, are members." But, in self-defence, we are forced to declare that the Epidemiological Society does not represent the mind of the medical profession at large, neither are the distinguished names just quoted of any weight in regard to the point in question. For instance, in a case of doubtful vaccination, I, for my part, own that I should not place the slightest confidence in the opinion of Sir B. Brodie, Dr. Babington, or Dr. Bright, because it relates to a matter in which they do not profess to be experienced. Hitherto, the humble but important service of vaccination has been deputed to the conscientious care of the family apothecary; nor have any of the learned bodies in medicine, surgery, or pharmacy, as yet recognised even so much as its existence at any of their several boards of examination. There is no certificate for a knowledge of it. It is not taught in the medical schools; it is left to the good sense and personal intelligence of each practitioner professing it. And now, after having been thus neglected, it is, all of a sudden, about to be legislated upon; and we are directed to look up to the members of a society only just starting into notice of their own accord, whose chief members are not vaccinators, while those practitioners actually skilled in vaccination are passed by unheeded, unnoticed, unconsulted, and not so much as respected for their testimony concerning those facts which they, and they

alone, are cognisant. Hasty and imperative legislation of this description can never be productive of any lasting and substantial good to the community.

I am, etc.,
J. A. HINGESTON.

Brighton, April 18th, 1853.

EVERY SURGEON HIS OWN VETERINARY IN CASE OF NEED.

LETTER TO THE EDITOR FROM J. I. IKIN, Esq.

SIR,—That noble and useful animal, the horse, so essential a part of the establishment of a medical man, well merits every care and the kindest treatment at his hands. The diseases and ailments of the horse should be studied by all young professional men, as they may become wanted in country districts where a skilful veterinary is not attainable; a *learned* blacksmith alone officiating in this capacity. We have the very highest professional precedents for the study of the anatomy and diseases of the horse, and for carrying our knowledge on this subject into practice. I need only name Sir Astley Cooper and Mr. Liston, both of whom had a thorough knowledge of the veterinary art, loved a good horse, and appreciated his value.

Sir Astley Cooper, as is well known by his old pupils, and the readers of his interesting Life and Memoirs, practised the veterinary art on a somewhat large scale, and bought up many castaways, or, as they are vulgarly but correctly termed, "dog horses", gave them a run out at grass, treated them skilfully, and thus in a number of cases obtained for himself many useful, if not valuable animals. Some of the best surgeons I have the pleasure of knowing have this *penchant* for doctoring their own beasts, as well as for enjoying the use of them. I would encourage this taste in the young surgeon, as a knowledge of the structure of any of the lower animals is never thrown away. A man who will ill-use a willing animal like the horse, ride or work him almost to death, and then neglect him if he is ill or happens an accident, or allow him to be neglected or summarily got rid of, is unworthy to have a good animal in his possession, and will be generally found to be a selfish, or, in plain English, a "bad fellow". Princes, nobles, judges, and even bishops and other church dignitaries, have not thought it derogatory to attend to the wants and superintend the *ménage* of their studs; so ought surgeons, especially young ones, in order to be able to *treat* a horse efficiently, and *buy* a horse at his value, or rather, which is more satisfactory, at a price *below* his value, without calling in the veterinary to pass and examine him, or feeling himself dependent upon the *wisdom* and judgment of a conceited groom.

Now for a case illustrative of these remarks:—

About three months ago, my servant was, contrary to orders, riding a five years old mare in the street, when she took fright at an omnibus, jumped sideways on to the causeway, and got her hind leg between the bars of an iron grating above a cellar window, her leg slipping down as far as above the hock, and she falling on her side, and the groom with her (he was not injured). In the mare's struggles to disentangle the leg, she stripped the integument off the leg from above the hock to near the fetlock joint; and the sharp edge of the grating, or the pieces of thick broken window glass (six squares of which were smashed) inflicted deep wounds in different directions, dividing a large artery above the hock on the inner side, a second branch just over the hock, and a third in the fetlock-joint below; and the latter spouted out through a small, round, but deep perforated wound, into which I could just insert the end of the little finger down to the bone over which the wounded artery appeared to run.

By raising the grate with a crow-bar, the mare, after some delay, was released, and with difficulty led to her stable, which luckily was close at hand. I was sought for, and soon on the spot, and found the poor creature in a sad plight, three jets of arterial blood spouting away across the stable from the wounded limb, above a quarter of a yard of lacerated integument flapping down with ragged edges, and deep wounds in different parts; the mare trembling, in a perfect clammy perspiration, with cold ears and cold extremities, and her heart beating with a quick, tremulous action. Not a moment was to be lost. I sent for another surgeon close at hand (my friend Mr. C. G. Wheelhouse), to aid me in tying the wounded vessels; and obtaining a helper or two to hold the mare (one the head, the other holding up the fore-leg), we stripped off our coats, turned up our sleeves, and proceeded to search for the wounded vessels.

finding the orifice, I seized the artery with a tenaculum (a strong one, of course, with a long handle—not a little jimcrack one, like those generally carried in a pocket-case), and with some difficulty we succeeded in tying the vessels at the above named three points. We then drew the integuments together as well as we could, and inserted a few sutures to keep the edges together if possible. This was a more difficult and even dangerous proceeding than the former, as the mare plunged violently when the wounded skin was pricked with the needle; and as we had no time, or the means at hand, to hopple her, the whole business was by no means either safe, easy, or pleasant. She was rubbed warm, bedded down, washed, the wounded limb enveloped in cold-water bandages, etc. I left. During the day and night, no hæmorrhage broke out, and I felt satisfied we had done all that could be done.

She never put her injured leg to the ground at all for some days; her general health suffered; and she, in the course of a few weeks, became a mere bag of bones. A veterinary saw her about a month after the accident, and gave it as his opinion that she was not worth keeping; and recommended me to be rid of her for what she would fetch. I did not act on this advice. I have kept her, and, though the sutures soon burst, and the wounds gaped, and had to heal from the bottom, and the supuration was most profuse, and we were a good deal teased with a large mass of proud flesh which sprouted up, and which required the persevering use of caustic and nitric acid to reduce, a cure was effected. The hair is growing nicely; the cicatrices of the wounds do not much disfigure her; for, from being inside the thigh and hock, they are not much seen. The use of the hock is regained, and, with the exception of a slight stiffness for the first five minutes after coming out of the stable, the mare goes well and soundly, and has been sold at more than I gave for her, but was taken back the same day she was bought, to oblige the purchaser, because he thought her too *gay* in harness. I have now ridden her several journeys, varying from five to thirty miles each; and she is as good a hack as need be ridden, and, with a little more condition, will be a very useful if not valuable mare.

If in this case delay or indecision had taken place, the mare must inevitably have bled to death (for she lost pools of blood as it was); or, along with the bleeding, have sunk from the effects of the shock from the fall and fright, both of which had to be overcome.

As I have had a good deal of experience with horses, and like them, I may be induced to give you a few other cases at some time, if it is not thought *infra dig.* to hold the opinion, and act upon it, that every surgeon should be his own veterinary in case of need.

I am, etc.,

J. INGHAM ILLIN, F.R.C.S., etc.

Leeds, March 26th, 1853.

ABUSE OF HOSPITAL RELIEF:—HOW PREVENTED AT THE MANCHESTER LYING-IN HOSPITAL.

LETTER FROM G. B. MARFEN, Esq., TO THE EDITOR.

SIR,—The abuse of hospital relief is now becoming so frequent, that the following suggestion of a means of preventing it, may not, perhaps, be *mal-apropos*. It is a plan which has been adopted at the Manchester Lying-in Hospital for some time with considerable success.

The patients are there admitted by recommendations, which, when presented, are registered by the secretary, and an officer of the District Provident Society is immediately sent to the residence of the applicant, to ascertain whether she is a proper person for admission. If he finds her family are in the receipt of not more than fifteen shillings per week, and that she is in other respects an admissible case, he acquaints the secretary therewith, and the patient is admitted accordingly; if otherwise, he tells her she cannot be relieved at this hospital, and the secretary returns the ticket to the recommender, with a notice to that effect.

This plan would of course require modification in different hospitals, according to the class of cases treated in them, but it may serve as a hint for some similar plan, which should materially diminish the indiscriminate dispensation of charity to persons well able to pay for medical advice and attendance.

I am, etc.,

GEORGE BELLARIS MARFEN,

Surgeon to the Manchester Lying-in Hospital.

Manchester, April 18, 1853.

PALPEBRAL TUMOURS.

LETTER FROM S. D. LEES, M.D., TO THE EDITOR.

SIR,—The volume of *Transactions of the Provincial Medical and Surgical Association*, lately published, contains a paper on "Palpebral Tumours", by Mr. Windsor, of Manchester. Some of these will no doubt be removed by suppuration; but gelatinous sacs, situated betwixt the orbicularis muscle and the conjunctiva, generally form a permanent deformity, unless removed by operation. I object to his plan of operating from the inside of the eyelid, as inflammation of the conjunctiva and fungous granulations will frequently ensue. I have been very successful in removing these tumours in the following manner:—Make a free incision of the skin along the upper margin of the tarsal cartilage, or over the centre of the tumour; separate the fibres of the orbicularis longitudinally; draw the cartilage downwards; transfix the sac with a tenaculum, and remove all the conical portion, with the contents, leaving the flattened base, which is firmly adherent to the conjunctiva, to be removed by absorption—a process soon effected; close the wound with fine sutures, and a narrow stripe of tissue plaster. In a week, the wound heals; and the cicatrix being in the line of corrugation, no deformity remains.

I am, etc.,

S. D. LEES, M.D., F.R.C.P. Edin.

Ashton-under-Line, April 9th, 1853

NEWS AND TOPICS OF THE DAY.

THE ROYAL COLLEGE OF PHYSICIANS AND THE UNIVERSITIES.

THE following letter has recently been addressed by Dr. HAWKINS, the Registrar of the Royal College of Physicians, to H. WADDINGTON, Esq., the Under Secretary of State for the Home Department:—

Royal College of Physicians, April 18th, 1853.

SIR,—I am directed by the President and Charter Committee of the Royal College of Physicians, to request that you would be pleased to lay before Viscount Palmerston the following observations upon a letter from the vice-rector of the University of St. Andrew's, a copy of which you have been good enough to transmit to them, by his Lordship's direction.

They cannot admit that the clause cited in that letter, from the proposed New Charter for the College of Physicians, will affect the *just* rights and privileges of the Universities, or their *legitimate* revenue.

The clause consists of two parts: the first of which states that it shall be lawful for the College to admit as a member, any person who shall have exceeded the age of forty years, on the production of satisfactory testimonials, and on his passing a sufficient examination; the second part enacts, that such person shall, after his admission, be entitled to have and to use the degree and designation of Doctor of Medicine. Strictly speaking, the clause cannot be said to confer any *new* power upon the College of Physicians. It was not, in fact, intended for the benefit of the College, but for that of a meritorious class of persons, to whom, when the College, in the exercise of powers which always belonged to it, shall have found them competent to practise as physicians, this clause concedes the designation or title by which physicians are usually known and addressed in this country. But the concession is limited to persons who have not had, and have no longer the power of obtaining, the advantages of an academical education, and who have no claim therefore to a University degree (which ought to imply that the holder of it has had that advantage), but who have established a claim to the rank of physician by their long experience, and by their eminent science and skill.

In a practical profession like that of medicine, it is always right that those who, by superior talents and industry, have raised themselves in public estimation, should have the power of rising from a lower even to the highest rank in the profession. It seems reasonable, that together with the legal authority to practise as physicians, for which such persons must apply to the College, the title should be granted which, through common usage, is necessary to render the license intelligible by the public, and useful therefore to the possessor of it. In this way, a want which is in some cases felt in the profession, may be supplied, and that too without substantial detriment to the Universities. For it is the earnest wish of the College that

such cases should be exceptional only; and that, as the rule, physicians should be induced, indeed compelled (as they will be by the New Charter), to resort to the Universities for their preliminary and general education.

In furtherance of this object, the College offers voluntarily to surrender, by the sixth clause of its New Charter, a portion of the powers which it has hitherto possessed, and to debar itself in future from licensing as physicians (except in the case above mentioned, of persons of advanced years and unusual attainments), any person whomsoever who shall not previously have obtained University degrees. A concession on the part of the College so important as this in favour of the Universities, ought in fairness to be taken into account, in connexion with the clause of the Charter which has been objected to. It may be allowable perhaps to mention that the College did not of itself propose or ask for this clause. It was spontaneously offered by Sir James Graham, when Secretary of State for the Home Department, on the ground that it is right and necessary that the rank of physician should be attainable by distinguished general practitioners; but that its attainment would be of little use to them, unless accompanied with the ordinary designation of doctor.

Of the deputation from the College of Physicians, which had recently the honour of waiting upon Viscount Palmerston, some members ventured to express to his Lordship a strong opinion, that no opposition was likely to be offered to the granting of the New Charter to the College. They did so with the greater confidence, because it has been understood that persons of authority in the English Universities, who were at first disposed to look with suspicion on this clause now brought into question, had, as soon as they understood its nature and object, readily withdrawn their opposition. The Committee of the College did not, therefore, anticipate any further objections to this clause, it being their sincere conviction that the New Charter, from its general tendency, and from the important concessions which it makes, is consistent with the just rights of the Universities, and favourable to their true interests.

I am further requested to direct that you would be pleased to lay before Viscount Palmerston the following observations on "The Memorial of the Members of the Gloucestershire Medical and Surgical Association", which his Lordship has referred to the President of the College of Physicians.

The President and Committee of the College cannot but agree with the memorialists, in considering the stamp duty charged on the licences of the College unfairly and disproportionately high. The duty on the licence of an apothecary, and on the diploma of a member, and that of a fellow of the College of Surgeons, is one pound only: whilst on the licence of the College of Physicians a stamp duty of £15 is imposed; and on the diploma of a fellow, a further duty of £25. They are utterly at a loss to understand why the difference should be so great. They have reason to know that the serious expense of a licence has deterred many persons from qualifying themselves according to law, and has tempted them to practise as physicians without being duly licensed thereto. Hence it may be safely concluded, that if the duty on the licences were lowered, many more persons would apply for them, so that a great public evil might be abated without loss to the revenue. They earnestly hope, therefore, that a considerable reduction will be effected by Government in the stamp duty imposed on the licences and diplomas of the College of Physicians, this being a measure which justice and policy seem both alike to dictate.

HEALTH OF WORKMEN.

It is well known to those who are alive to such matters, that a series of most important plans for the benefit of the workmen are carried out in Price's Patent Candle Manufactories, at Vauxhall and elsewhere, by the resident directors, the Messrs. Wilson, who manage the establishments for a company. These works employ a large number of men and boys in operations requiring care and delicacy; and the Messrs. Wilson have for several years been engaged in educating, religiously, intellectually, and physically, those employed by them, so as not only to make them better and happier men, but more conscientious and diligent workmen; and the result has been, that the plans have succeeded financially to an extent not anticipated. The public, since being acquainted with them, especially by an article in the *Quarterly Review*, have patronised these laudable exertions by buying more candles; so that the business has greatly increased, and the boys and men, who have been treated with such considerate kindness, have done their work better, and worked with greater spirit and diligence.

We write this by way of introduction to a part of a proposal, in a recent report, for giving the men more holidays, in order to improve their health and increase their powers of work. In proposing to the company a fortnight's holiday in summer for those workmen who cannot, from the nature of their work, get the half-holiday on Saturday, Mr. J. Wilson says:—

"It would be almost the making of a man or boy, after a year's hard work, to pay him a fortnight's wages, and to let him go for that time to friends in the country, if he has any, or if he has not, then to the sea-side. He comes back, especially if a boy, a different creature from what he was when he went away, in point of vigour of body and mind, and fitness for another year's hard work; and for such hard work as ours is at present, a man or a boy at his best, in these respects, will not find that he has much vigour to spare. We have sometimes seen a valuable man flagging at his work, being evidently in a state in which it was too much for him; and we have, as a matter of pecuniary interest to the company, sent him off for a holiday for a week or two, without stopping his wages; and the experiment, considered as an economical speculation, has completely succeeded.

"Upon this proposal of a fortnight's holiday in summer to some of those deprived by the nature of the work of the weekly half-holiday, we would remark, in deprecation of our being thought to propose something too much out of the course of common factory management, that all engaged in the counting-house have, as a matter of course, three weeks' holiday in each year, and that we ourselves get holidays as we can; and this without any doubt in our mind that holiday-making is a positive saving of time in the long run, from the greater power of work given by it. And we would state, that the result of our observation here, both in such little chance opportunities of observation as those above noticed, and on such others as are afforded us by those of our men who are able to make visits to the country on their own funds, is, that the value of holiday and changes, so generally admitted in the case of those who work with their heads, holds good also, although not generally thought to do so, in the case of those whose work is chiefly bodily. We believe that such holiday-makings as are here proposed, whether the weekly or the Saturday half-holiday, in all cases where the people are already far enough advanced to be out of danger of mis-spending the time so given them, would be one important means of arresting the sad physical degeneration notorious in city working people, and which made a recruiting officer assert that it would be impossible in all Manchester to raise a regiment of dragoons: and if this be so, then our point is proved, that holiday-making is as much saving of time to body-workers as to mind-workers.

"It is possible that, for the many cases of boys weakened through sickness so as to need change, and yet without friends in the country, and not themselves such as could well be trusted alone, the best and cheapest way of carrying the plan out will be, that the company should have some place at Margate or elsewhere, with a trustworthy person in charge of it, to receive and look after them."

We feel that no apology is necessary for the length of these quotations, full as they are of practical experience and of good sense; as so many of our readers must be in the condition to give similar advice to master-manufacturers, as to the importance economically of attending in this way to the health of their workmen.

METROPOLITAN CHURCHYARDS. "Experience proves that burial in large towns cannot be confided to the parochial authorities; and if Government could enforce good management on their part, it cannot find 200 convenient spots to replace the 200 which must be closed. If the parish authorities and the clergy cannot be trusted, how can private individuals and joint-stock companies? Nothing then remains but for Government to take the matter in hand, and, as in other countries, to ensure a dignified and a sanitary burial to all classes at reduced rates, in one or in several large cemeteries, according to the scheme reported on by the Board of Health. All metropolitan churchyards might then at last be closed; and with regard to those receptacles of corruption called vaults, for three months the friends of those deposited there might be allowed a faculty to remove the remains free of expense. After which period, vegetable charcoal and lime might be thrown within them, and all ventilation and communication between them and the superposed churches should be prevented—Westminster Abbey and St. Paul's being the sole exceptions to this law."—*Lancet*, 10th April 1853.

PRESENTATION OF PLATE. On Tuesday, the 14th instant, Dr. Babington gave a *conversazione* to the members of the Epidemiological Society and their friends. In the course of the evening, Dr. Babington presented to Mr. Tucker a silver plate, with an appropriate inscription, intended to be affixed to a *secretaire*, as a testimonial of the sense entertained by the President and other members of the society of the value of Mr. Tucker's services as one of the honorary secretaries, and especially of the honour due to that gentleman as the founder of so important a society. In presenting this testimonial, Dr. Babington expressed himself as follows:—

"A few friends, including myself, being deeply impressed with the zeal and ability which you evinced, first in originating, and subsequently in establishing the Epidemiological Society, and admiring the untiring energy which you have since exerted in endeavouring to promote its objects,—have felt anxious to manifest their sense of your merits and services by requesting your acceptance of some token of their regard.

"It is with much pleasure, therefore, that, in fulfilment of their wishes and my own, I present you with this inscription, to be affixed to a *secretaire* which, however small its intrinsic value, we have selected as an appropriate offering for one who has so efficiently fulfilled the very arduous duties of honorary secretary to our society."

To which Mr. Tucker replied:—

"I accept with much pleasure the testimonial of approbation for the services it has been my pride to render to the cause in which you and others are so warmly interested: it is the cause of suffering humanity. I shall always look back with great satisfaction at having been the originator of a society which has displayed, even in its very infancy, its capability of doing great good.

"To those friends who have joined with you, Mr. President, in presenting me with this mark of their esteem, I hope you will convey my sincere and heartfelt thanks, and I beg you to accept the same yourself, sir, for the very kind and flattering expressions which you have been pleased to use in presenting it."

ACCIDENT TO PROFESSOR LIEBIG. The *Augsburgh Gazette* has the following from Munich, dated the 10th:—"Professor Liebig was last night giving a lecture on Chemistry at the palace, before Queen Maria, Queen Theresa, King Louis, the younger branches of the royal family, and some persons belonging to the court, when a bottle of oxygen gas, being improperly handed to him by his assistant, who took it for another bottle, an explosion took place, and the bottle flew into a thousand pieces. Fortunately, the explosion occurred in an inner room, the door of which was open; still some fragments of the glass passed through the door, and slightly wounded some members of the royal party who were sitting in the front rank. Queen Theresa was cut in the cheek, and the blood flowed in abundance; Prince Luitpold was slightly wounded in the forehead, Countess Luxemburg in the chin, and Countess Sandizell in the head. None of these wounds will be of any consequence. The professor was also slightly injured, having escaped with his life by a sort of miracle."

INQUEST ON DR. RICHARD CHAMBERS. On April 19, Mr. Wakley held an inquest at the Weymouth Arms, Weymouth Street, Portland Place, on the body of Dr. R. Chambers, late of Wimpole Street. Dr. Marris Wilson, of Upper Charlotte Street, Fitzroy Square, who had made the *post mortem* examination, stated that on opening the body he was struck, as were other medical gentlemen present, with the odour of prussic acid. He found the right ventricle of the heart double its natural size. The phial found by the side of the deceased smelt strongly of prussic acid, and upon reference to the prescription from which its contents had been compounded, he found that the deceased had prescribed for himself six drops of prussic acid, of Scheele's strength, with ten drops of Battley's solution of opium, one drachm of colchicum, two of acetate of ammonia, and an ounce and a half of water. He believed that the deceased had taken this as a medicine, and that owing to the disease of the heart the prussic acid had caused death. The jury, after hearing other evidence, found—"That the death of the deceased was caused by a diseased heart, under the influence possibly of prussic acid taken medicinally."

UNIVERSITY OF LONDON. The Senate has recommended the appointment of a special Examiner for Forensic Medicine; and of a second Examiner for Midwifery. A second Examinership in *Materia Medica* is also talked of.

ROYAL COLLEGE OF SURGEONS:—PASS LIST. The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 15th instant:—Messrs. Frederic Savignac Stedman, Great Brookham, Surrey; Thomas Chambers Palmer, St. Kitt's, West Indies; William Robert F. Marchant, North Curry, Somersetshire; William Steventon, Cheadle, Staffordshire; William Gabb Jenkins, Aberystwith, Cardiganshire; James Robert Tunmer, Ipswich, Suffolk; Thomas Howarth Cockcraft, Keighley, Yorkshire; William Hogarth Adam, Royal Navy; John Brake, Tottenham; Thomas Francis Edwards, Denbigh, Denbighshire; Harry Leigh Aikinson, Weaverthorpe, Yorkshire; and Thomas William John Goldsborough, Welchpool, Montgomeryshire.

On the 18th instant.—George Pigott Barton, Rolands Castle, Hants; David Cremen, Cork; Wynne Peyton Frazer, Dublin; Marcus William Mott, Church Stretton, Shropshire; Charles Turner, Grantham, Lincolnshire.

The following gentlemen, having undergone the necessary examinations, were admitted licentiates in midwifery at the meeting of the board on the 13th instant:—Messrs. John Edmunds, Wrexham, diploma of membership dated August 4, 1852; Thomas George David Davies, St. Andrew's Court, Holborn, March 23, 1853; John Vinal, Hackney, April 29, 1839; James Nicholls, Trekenning, October 15, 1852; Octavius William Hoffman, Reading, March 23, 1853; John Tibbitts, Warwick, March 23, 1853; John Thomas Muriel, Ely, July 2, 1852; Oscar Byrne, Newcastle-under-Lyme, April 4, 1853; John Humphry, Birmingham, March 30, 1849; Thomas Lawes Rogers, Alvediston, Wilts, April 8, 1853; Frederick Augustus Stutter, Wickhambrook, April 11, 1853; Samuel William North, York, December 3, 1852; and Thomas Fisher, Buckfastleigh, Devon, April 18, 1845.

The Jacksonian prize has been awarded to Mr. H. Thompson, Surgeon to the Blenheim Dispensary, for his essay on Stricture.

APOTHECARIES' HALL:—PASS LIST. Thursday, April 7th, 1853. Slade James Baker, Upper Hayford, Oxon; Robert Bianchi, Como, Italy; Samuel Cardozo, Australia; Maurice Griffith Evans, Bleanafon, Carmarthenshire; William Harrison, Gargrave, Yorkshire; Charles Hemming, Kimbolton, Huntingdonshire; Thomas Lewis, Llandilo, Carmarthenshire; Arthur Edwin Temple Longhurst, Kirkby Mallory, Leicestershire; Thomas Alexander Moore, Preston, Lancashire; Charles Sedgwick, Maidstone; David Augustus Martin Talbot, Wraxall, Somersetshire; Frederick William Teanby, Stert, near Bridgewater; William Edward Wedge Vaughan, Crewe; Joseph Haydon Ward, Epsom.

April 14th. John Archer, Saffron Walden; H. L. Atkinson, Weaverthorpe, Malton, York; Thomas Henry Cheate, Burford, Oxon; Edward James, Exeter; Charles Watson Kitching, Smarden, Kent; David Mathias, Cardigan; Fred. Northover, Winchester; William Parker, Brightlingsea, Essex; Edward Prentice, North Walsham, Norfolk; Richard Thomas, Llanelly; W. Walker, London; John Wright, Mountsorrell, Leicestershire.

DR. HENRY HOLLAND. The Queen has conferred a Baronetcy upon this distinguished physician, one of Her Majesty's Physicians Extraordinary.

LETTSOMIAN LECTURES. Mr. Pilcher will deliver his Lettsoman Lectures before the Medical Society of London, on May 9th, 16th, and 23rd. The subject of the lectures will be "Observations on the Nervous System."

MEDICAL BENEVOLENT COLLEGE. It is with much pleasure that we notice the influential list of stewards which appeared in our advertising columns of last week, for the forthcoming festival. A great deal has already been done towards the attainment of the objects contemplated; but the support and co-operation of the profession are still necessary to ensure their speedy consummation. We hope to meet on the festival many of our provincial brethren, several of whom, we are glad to observe, have volunteered their services as stewards. The amount already subscribed is upwards of £13,000.

OBITUARY.

(*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.)

AFFLECK, Duncan, Esq., Staff-Surgeon, at St. Vincent, West Indies, of Yellow Fever, on March 7th.

BLAIR, Thomas, M.D., at Brighton, on April 15th, aged 89.

BULLIN, Francis, Esq., Surgeon, at 26, Farringdon Street, on March 29, aged 66.

***CREASY, William, Esq.,** Surgeon, of Edenbridge, Kent, recently.

GALE, Gabriel Joseph, Esq., Surgeon, at Newington, Surrey, on March 27, aged 52.

GRANT, Augustus, Esq., Surgeon to St. Marylebone Workhouse, at 21, Thayer St., Manchester Sq., on March 28, aged 28.
 HORLEY, William, Esq., Surgeon, at Hoddesdon, Herts, on April 25th, aged 55.
 KITTERMSTER, H. F. G., Esq., Surgeon, eldest son of Dr. Kittermaster, of Meriden, Warwickshire, at Warwick, Canada West, on March 10th.
 LEGGATT, Richard S. Esq., Surgeon, at Eastry, Kent, on March 13, aged 67.
 MARTER, William, Esq., Surgeon, at Worthing, Surrey, on April 2, aged 65.
 M'BAN, J. A., Esq., Staff-Surgeon, eldest son of the late Lieutenant-Colonel James M'Ban, 78th Highlanders, at Lucoa, Jamaica, on January 17th.
 SEWELL, George, Esq., of Castle-Hedingham, Essex, on March 12, aged 52.
 THOMPSON, William Henry, M.D., at 28, Osnaburg Street, Regent's Park, London, on March 29, aged 92.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

BROOKE, Charles, Esq., elected Surgeon to the Westminster Hospital.
 DAVIS, George Millett, Esq., elected Surgeon to the Liverpool Northern Hospital.
 HILLMAN, Wm. Augustus, Esq., elected Assistant Surgeon to the Westminster Hospital.
 JOHNSON, Athol A., Esq., elected Surgeon to the Hospital for Sick Children (Great Ormond Street), vacant by the resignation of G. D. Pollock, Esq.
 WOODFALL, J. W., M.D., elected Physician to the West Kent Infirmary, in the room of the late Dr. Sibbald.

NEW SERIES.

BRANCH MEETINGS. The Metropolitan Counties Branch meets on Tuesday, the 10th, at 37, Great Queen Street, when Medical Reform, the Vaccination Bill, and other matters of importance, are to be brought forward. Vide p. 407.

THE YORKSHIRE BRANCH meets on Thursday, the 12th, at York, when Medical Reform and other questions will be considered. Vide p. 400.

THE EXCISE ON SPIRITS A TAX ON MEDICINE.

OF the minor changes proposed by the Chancellor of the Exchequer and forming a portion of a Budget, which, be its merits or faults what they may, lacks not variety, those affecting the spirit duties in Scotland and Ireland are not the least significant; since they evince a desire to grapple with the evil of differential excise duties within what must, in this matter by courtesy alone, be termed the United Kingdom. The right honourable gentleman also yields to importunity, what has long been denied to a just claim. He proposes "to relieve the distiller, and likewise the time of the House, by making an allowance for waste upon spirits in bond"; a concession which should encourage us, who form no inconsiderable a fraction of that unhappy "twenty-second part of those whose case appeals to the sympathies, but which is so limited in comparison to the whole range of the income tax that it would be a pity to be compelled to break up the tax on their account", to call (both in season and out of season) for relief from this iniquitous burden, until like the importunate widow in the parable, we wring from the annoyance and weariness of our rulers the justice denied to our wrongs. Moreover, this alteration of the spirit duties in the sister kingdoms manifests a determination on the part of the Chancellor of the Exchequer to advance in the right direction, and in accordance with his declaration that "one great object of our financial policy would be the equalization of the spirit duties between the three countries". It shows that he is undeterred by the failure of his predecessor, who after raising the Irish duty on spirits a shilling per gallon in 1842, was forced to return next year to the old duty—an actual loss to the revenue having accrued, together with an increase of persons committed to gaol for illicit distillation, in the ratio of nearly ten to one.

It is much to be desired that this policy of equalizing the spirit duties be persevered in by the Government until they are assimilated to those of England, since nothing, we are convinced, is more essential to the commonweal than that the consumption of spirits should be checked as much as possible in this kingdom, and the use of other beverages, whether fermented or not, encouraged in their place. A measure tending to check this consumption is a subject of congratulation, especially when we see wages rising, and when we see increasing amongst artizans and labourers unthrift and drunkenness, the too common concomitants of a high rate of wages. And we look forward with anxiety to the completion of the great object announced by Mr.

Gladstone, the equalization of the spirit duties between the three countries, as one deeply involving the health and morals of the population.

When this equalization has been effected, it would be a source of still further satisfaction to us were even a higher rate of duty than now exists on distilled spirits in England levied throughout the kingdom; especially, were this accompanied with such a modification of the malt and wine duties as to make beer and wine decidedly the cheaper excitants,—since men will drink, let us say what we will,—and thus to discourage the use of the more injurious stimulants. An efficient check to the consumption of spirits would strike a heavier blow at pauperism, disease, and crime, and raise the condition of the people far more quickly than any educational or sanitary measures within the ability of the Government to pass in a country like ours, where so great an amount of liberty and self-regulation is confided to the citizen, both in his individual and in his corporate capacity.

A minor benefit arising from the future equalization of these duties will be the riddance from the vexatious restrictions now requisite to prevent the smuggling of spirits or their products made in one part of the kingdom into another; a system of *octroi* no less opposed to our present commercial policy than it is to our national habits.

Beneficial, however, as the spirit duties unquestionably are, they involve, as now levied, injustice to particular classes, which reacts on the community; an injustice which Mr. Gladstone has acknowledged in the proposed remission of duty on the waste suffered by the spirits kept in store by the Scotch and Irish distillers. This remission, we submit, should be extended to all who use spirit for purposes of manufacture. Far more should this exception be made in favour of those under whose administration it oftentimes truly becomes *aqua vita*, whether employed directly as the fittest vehicle in which to administer a drug, or as a medicine to rally the energies of the sinking frame; or, indirectly by the manufacturing chemist in the preparation of the more valuable of our therapeutic agents, or by the analyst in wresting from nature that knowledge which has an immediate and enduring influence on the healing art.

To levy a duty upon the raw material of a manufacture is in direct opposition both to our present free trade policy and practice. The expiring excise on soap is a case in point, the duty on this article of manufacture having been remitted to the makers of woollen cloths and the kindred trades; and we contend that this principle should be extended to the parallel case of distilled spirits. Varnish-makers, hatters, etc., have been enabled to substitute in most cases wood-spirit for alcohol; a replacement impossible alike to the retail druggist, the perfumer, the manufacturing chemist, the analyst, and the medical practitioner. To the first, the injury is little if any, since he must and does charge the consumer both with the duty and the waste of spirits. This remark equally applies to the wholesale druggist; but this duty amounts almost to a prohibition

of an important branch of his business, for the manufacturing chemist who, could he obtain spirit duty free, would make the alkaloids and other delicate preparations requiring enormous quantities of alcohol and ether to extract them advantageously; whereas now, with a few exceptions where the processes are kept secret, the British manufacturer is forced out of the home market which he is compelled to abandon to his foreign rival, not through his own incapacity or inability to meet this competitor, but, because he is unfairly weighted in the race, in the shape of an enormous tax upon the most important article he would employ in his manufacture.

On the progress of scientific chemistry in these kingdoms, this duty is an incubus which has succeeded in stifling many a valuable discovery having most important bearings upon medicine, agriculture, and the arts of life; for the British analysts are so trammelled with this enormous tax on science, that, as a body, they almost abandon these vast fields of research to their continental brethren, simply because they cannot afford to use the alcohol and ether, essential to such investigations, in the abundance and profusion required. Thus British chemistry is paralyzed by the pressure of this excise, and forced to occupy a rearward position in the progress of science.

With regard to its action on ourselves. To the young practitioner, or union doctor, whether in town or country, whose patients are almost or altogether of the poorer class, the druggist's bill is a serious item. The remembrance of this inevitable visitor does and must influence him in dispensing; it leads him to seek for less expensive forms of medicine than tinctures, ethers, salts of quinine, etc., for those cases where, he too well knows, the probability of payment of any kind is always slight, and is never on a scale to justify the use of costly medicines if he can possibly employ cheaper ones, unless he is content to lose, not only time and labour, but also such an amount of money into the bargain as he is neither called on nor is able to afford.

A remission of the duty on spirit used in science and medicine, would not merely be a pecuniary advantage, and to its extent a compensation for undue taxation to many of us, but also, by the impetus given both to scientific and technical chemistry, it would enable our country to regain its once proud position in these departments of science and art. We see but little difficulty in carrying out the abatement which we propose, since the same machinery now in action with respect to the remission of the excise on soap to the makers of woollens, might be adapted to the excise on spirit employed either for scientific or medicinal purposes.

THE MEDICAL REFORM BILL.

We mentioned in our last number, that Mr. Hastings had communicated with Lord Palmerston on the subject of the Bill of the Association, and we are now in a position to report the result of that communication. Though not of a nature to discourage the advocates of Medical Reform, it is sufficient to rouse them to every exertion, lest the present favourable opportunity of settling the question should be lost.

Lord Palmerston, it appears, has hitherto found his hands so fully occupied, that he has not had time to take up the Bill; nor is it probable, considering the overburdened state of the Commons' House of Parliament, that the Bill, if introduced

there late in the session, would pass into law. Under these circumstances, Mr. Hastings (who is in constant communication with the rest of the Committee), has thought it best to make an effort to introduce the Bill into the House of Lords. We believe that arrangements with that object are being made for a deputation to wait on Lord Aberdeen on an early day, probably on Thursday the 12th.

But it is evident that this is not all that must be done. The profession must help themselves, and that immediately. By forwarding petitions to Parliament we shall best call the attention of Government to the nature of our grievances, and prove to them the strong feeling that exists on the subject. Let a meeting of medical men be convened as soon as possible in every town; let a petition be adopted, signed, and forwarded to the member for the district for presentation to the Commons, and to some noble lord for the Upper House. Numbers of petitions, from various places, produce much more effect than a few numerously signed. The time for vigorous action has now arrived; and we trust that every member of the Association will remember this, and do his duty.

In another part of this number will be found a report of a meeting of the South Western Branch, at which considerable hostility was expressed to the Bill. So far as we understand the subject, the gentlemen of the South-Western Branch object to some of those portions of the Bill which have commanded most general assent. They object to the third clause, because it does not compel the election to the Council of a certain number of provincial practitioners. But formally to stipulate for this would be to perpetuate division, and to indefinitely postpone that harmony and merging of antagonistic classes which the profession so much requires. They complain that no superintendence over the funds is provided for; forgetting that there is a clause requiring a yearly audit. They complain that every practitioner is, *in futuro*, to be a member of one of the Colleges; but this, so far as our correspondence enables us to judge, is one of the most approved features of the Bill, inasmuch as it will do away with any third class in the profession. It will raise many, and degrade none.

When the Bill is before Parliament, the profession can freely express its opinions upon matters of detail. In the mean time no one will compromise his individual opinions by signing such a petition as that which we subjoin; and, as we have already said, unless Parliament and Government be thoroughly satisfied that the medical profession are in earnest in their entreaties for Medical Reform, it is very certain that no such measure will ever receive the sanction of the legislature.

To the Honourable the Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled: the humble Petition of the undersigned Members of the Medical Profession, residing in

SHREWETH,—

That the laws at present in force relating to the practice of medicine in this kingdom are in a confused and unsatisfactory state, and that your petitioners are thereby hindered in the lawful pursuit of their calling, and in their investigations of medical science.

And your petitioners therefore humbly pray your honours the House to take such immediate measures as in your wisdom may seem expedient, for the better regulation of the Medical Profession.

And your petitioners will ever pray,
(Signatures.)

We understand that the subject of Medical Reform is to be brought forward at the meeting of the Association

Counties Branch upon the 10th, and at the meeting of the Yorkshire Branch on the 12th current. It is very important that these meetings should be well attended, so that all shades of opinion be represented in fair and free discussion. It will then be discovered whether the Bill now in the hands of Lord Palmerston has or has not obtained the support of the profession. So far as has yet transpired, the Bill has received an unparalleled amount of support from the profession. It is supported by the College of Physicians of London, by all the Scottish Colleges, and what is of more importance than Corporation patronage, it appears to be in favour with the general body of the profession throughout the kingdom. Is such a measure to be allowed to fail for lack of timely aid? This cannot be, if the ASSOCIATION rouse itself to an effort worthy of the power which it possesses, and support its founder and his colleagues of the Reform Committee in fighting what may be a hard fight, though it be one which must ultimately be crowned by a victory.

THE JENNER MONUMENT.

OUR attention has been directed to a recently published list of subscriptions towards the erection, in bronze, of Mr. Calder Marshall's statue, as a monument to Jenner. This admirable work of art is, doubtless, familiar to many of our readers, as it was a prominent object of interest (near the crystal fountain) in the Great Exhibition of 1851. The list to which we refer has once appeared in our advertising columns; and to day a summary of the former advertisement is inserted, from which we derive the following information.

America	£329 12 8
Sweden and Norway	83 10 4
Russia	100 0 0
Other Nations	29 11 0
Great Britain and Ireland	153 2 5

The position which our countrymen here occupy is unworthy of the compatriots of Jenner. Much of the blame, however, must be traced to the energies of the Committee having been exerted fitfully over a long period, and not concentrated within a short space of time, as is essential for the success of collections of money. The exertions must be vigorous and unceasing, for if public interest be allowed to cool, the rekindling of it is always difficult; and the best schemes, be they literary, political, scientific, commercial, or philanthropic, are apt to be permanently injured when languidly promoted in any part of their career. Now we complain that the Jenner Monument Subscription has not been kept with sufficient steadiness before the profession and the public. An amount of money sufficient not only to erect Mr. Marshall's statue, but to endow professorships and scholarships in honour of Jenner, might, we feel convinced, have been collected long ere now, had the agitation, which is usual and necessary in such cases been adequately maintained. We trust that as the subscription has been recommenced, it may now be carried on with the vigour and success which it deserves.

The appeal of the Committee is very properly addressed to "all nations, and to persons in every station of society", who have felt the obligations they owe to the discoverer of vaccination: and we may well ask, Who has not? Still, the appeal comes home with peculiar force to members of the medical profession. Jenner was a medical prac-

titioner in a country village; but nevertheless his name is the greatest and the most effulgent in the annals of medicine. When men of all nations, and of every position in society, are uniting to honour his memory, it is especially right for us, as his brethren of the healing art, and as better able than other classes of society to appreciate the vastness of the boon which he conferred upon humanity, to be foremost in aiding the Committee, not only by bestowing contributions to the fund, but likewise by collecting the donations of such friends and patients as may wish to assist in furnishing the very moderate sum which is yet unprovided. The smallest and the most liberal donations are equally acceptable to the Committee; and we are inclined to recommend collectors to solicit small sums from everybody, rather than to be anxious to obtain large sums from the wealthy. A good example of the policy of asking small contributions is afforded by what was done in Boston by Drs. Jackson, Ware, and Warren; where, although the maximum subscription was limited to one dollar, the aggregate of the dollars amounted to £200, the largest amount yet received from any country or district.

MEDICAL FEES AND LIFE INSURANCE COMPANIES.

THE following paragraph in a recent number of the *Glasgow Herald* has attracted our attention. Surely, the refractory Insurance Companies, now that law as well as justice declares against them, must at last give in.

On Thursday last a case was called in the Glasgow Sheriff Small Debt Court (Sheriff Skene presiding), involving a long-disputed point between the medical profession and certain Life Assurance Companies. The parties were Dr. Matthew Wylie, and Mr. W. L. M'Phun, agent for an English Life Insurance Company. The amount sued for was 10s. 6d., being the usual fee (?) in such cases. Dr. Wylie stated that the schedule (which he handed to the Court) for examination was sent to him blank by Mr. M'Phun. He had filled it up, and returned it, with an intimation that his charge for so doing was 10s. 6d. The schedule was sent to London, and had been retained four days, being quite sufficient time to make use of it, when it was returned with an intimation that the company did not recognize the claim of any medical man, referred to by a party proposing to insure his life with them, to remuneration for filling up the schedule sent in consequence of such reference. In order to try the point, he (the Doctor) had summoned the company's agent. For Mr. M'Phun, it was said that he had not employed Dr. Wylie—that the company never did pay the fees of medical referees, and that this had been mentioned at the time the schedule was left at his office. Sheriff Bell gave his decision in favour of the claim of Dr. Wylie.

We regret that the name of the shabby and dishonest company represented by Mr. M'Phun is not mentioned. Nothing short of a dread of losing business produces any effect.

ORIGINAL COMMUNICATIONS.

ABNORMAL MENSTRUATION.

By W. S. OKE, M.D., Senior Physician of the Royal South Hants Infirmary.

DEFICIENT MENSTRUATION, NOSOLOGICALLY TERMED CHLOROSIS.

THIS disease for the most part occurs in unmarried females, at any time from puberty to about the age of twenty-eight. It generally arises from want of the open air and exercise: hence, it is more frequently met with in domestics employed in close apartments, and in persons constantly seated at needlework. It is rarely observed in married women.

The aspect of the patient is pallid or pale, and the lips have little or no colour. There is a total absence, diminution, or unhealthy condition of the menstrual secretion; and often leucorrhœa. The pulse is feeble, and the tongue clean and flabby. There is palpitation of the heart upon the slightest excitement; and on placing the stethoscope over the right internal jugular vein, a little above the clavicle, a peculiar humming sound is heard. The respiration is embarrassed by the least exertion, especially on going quickly up stairs. The digestive organs are disordered; there is pain of the chest under the sternum, or of the left hypochondriac region; and there is sometimes giddiness, at other times severe neuralgia of the head or face. There may be also a depraved appetite; but I have not found this a frequent association. The bowels are costive or relaxed; and the urine either high coloured and scanty, or pale and copious. There is weariness and coldness of the lower extremities, and perhaps œdema of the ankles, great inactivity, depression of the spirits, and a disposition to shed tears.

With regard to the pathology of chlorosis, it would appear that the insufficiency of the menstrual secretion, the want of colour of the skin, and, in short, the languor of the vascular and nervous system, are the results of a low condition of the blood, caused by a deficiency of iron in its globules, which is probably necessary to their normal colour and invigoration. That iron is a constituent part of the blood-globules, is shown by Berzelius, in the third volume of the *Med.-Chir. Transactions*. At page 215, he writes: "I incinerated 20 grammes (400 grains) of colouring matter (crassamentum) till the charcoal was completely destroyed, and obtained 0.25 grammes (5 grains) of ashes, having a yellowish red colour. By an accurate analysis, I found it composed of

Oxide of iron	50.0
Subphosphate of iron	7.5
Phosphate of lime with a small quantity of magnesia	6.0
Pure lime	20.0
Carbonic acid and Loss	16.5

100.0"

Liebig also states, "that the leading characteristic of the red globules is, that they contain a compound of iron found in no other constituent of the body, and that they have the power of combining with gases, as evidenced by the change of properties which they suffer when exposed to their action".* And that iron is also conducive to the colour as well as to the vigour of the blood-globules, may be inferred from the fact that no disease can be more certainly and directly cured by the efficacy of medicine, than chlorosis by the internal adhibition of some of the preparations of this metal.

It has fallen to my lot to have had extensive experience in the treatment of this disease; and I can confidently affirm that, where this atonic condition of the system is not complicated with any co-existing organic disease, the fol-

lowing simple treatment has seldom if ever failed of complete success. One of the pills (a) is to be taken every other night, and two of the pills (b) three times a day:—

- (a) R Hydrargyri chloridi gr. xij.
Pilulæ aloes cum myrrha gr. xlvij.
Syrupi, q. s.

Misce et divide in pilulas xij.

- (b) R Pilulæ ferri comp. 3ijj.

Divide in pil. xxxvj.

If there be diarrhœa, the pills (c) are to be taken instead, leaving out of course the aperient:—

- (c) R Pilulæ ferri comp. 3ijj.
Pulveris opii gr. iv.
Syrupi q. s.

Misce et divide in pilulas xxxvj, quarum capiat duas ter die.

It occasionally happens that an individual cannot swallow medicine in the form of pills, in which case (d) may be prescribed with equal success:—

- (d) R Misturæ ferri comp. ʒviii.
Decocti aloes comp. ʒiv.

Misce. Capiat ʒiss. ter quotidie.

If necessary, the bowels may be regulated by the powder (e), taken in jelly:—

- (e) R Hydrargyri chloridi gr. j.
Aloes socot. pulv. gr. iij.
Pulv. cinnamomi comp. gr. ij.

Misce. Fiat pulvis noctibus alternis sumendus.

Amongst the better classes of society, the patient is often sent to the sea-side, or some other place, for change of air, without the aid of medicine; but this is at best a tedious remedy, if it be a remedy at all: whilst the treatment above recommended will bring about convalescence in six weeks or two months, without any change of locality.

CASE. A married lady, aged 26, who had never been pregnant, having been for a considerable time deficient in her monthly secretion, and having lost all her colour, was sent to Italy for the improvement of her health. After many months, she returned without the slightest benefit, and as pale as death. Being placed under my care, she was directed to take the mixture (d); and, as her stomach was very irritable, she was restricted to the lightest nutriment, with weak brandy and water as a beverage. Under this treatment she soon began to mend, and in about three months regained her strength and colour.

In chlorosis, the diet should be light and nutritive, with one glass of wine daily. Walking or riding exercise should be taken in the open air; and the warmth of the body, especially of the lower extremities, should be maintained by adequate clothing.

NEURALGIC MENSTRUATION, NOSOLOGICALLY CALLED DYSMENORRHOEA.

The menstrual secretion is sometimes commenced and accompanied with severe neuralgic or spasmodic pain of the lower part of the abdomen, back, and hips. The amount of suffering varies in different individuals; and it appears to be caused by a morbidly sensible condition of the uterine nerves, which arise from the sympathetics and sacral. This disease usually affects the unmarried, and may be excited by moral as well as physical causes. There is generally a deficiency of the menstrual secretion; but, unlike the foregoing affection, it is not characterized by pallor of the countenance, nor is it by any means so readily cured. In some cases, it is true, the pain may be alleviated by the hip-bath, by opiates, belladonna, digitalis, purgatives, electricity, and, especially if it be of an inflammatory character, by cupping over the sacrum; but in others the pain is so severe as to admit of scarce any relief during the period. This at least had been the result of my own experience for many years, till a most inveterate case at length yielded to treatment.

CASE. A lady, aged 26, well formed, and of dark complexion, from a disappointed attachment had become deficient in her menstruation; and the diminution was accompanied with hysterical paroxysms, and the most intense pain of the uterine region, as soon as the secretion commenced.

* As quoted by Brande, in his *Manual of Chemistry*.

This state of extreme suffering continued for some years, and rendered her existence quite wretched. She had consulted a variety of medical men, and many remedies had been tried, to remove or alleviate her pains. She had been locally bled, had frequently used the warm hip-bath, with purgatives, opiates, antispasmodics, etc.; but all these means had fallen short of any permanent relief. The only remedy which had given her any respite was large doses of the liquor opii sedativus, although it always disordered her system. In such a case as this, as all ordinary remedies had been found unsuccessful, and reflecting that the indication of cure was clearly to subdue the morbid action of the uterus, and restore its normal secretion, I resolved to combine some preparation of iron with a sedative which would not contract the secretory cavity of the uterus; accordingly, she was immediately placed under the following treatment:—

Rx Pilulæ ferri compos. 3ij.
Extracti conii 3j.

Misce et divide in pilul. xl, quarum capiat duas ter quotidie.

This plan was steadily observed through the interval up to the next period, after which she wrote to me, stating that it had passed with an increased secretion, and without suffering or hysteria. The treatment was persisted in for some months with complete success; and two years have elapsed without any return of suffering. I considered this an important case; and, as others of a similar character came under my notice, they were placed under the same treatment, and almost always with a successful result. Opium, in one shape or another, will doubtless, in large doses, afford temporary relief to the severity of the pain in dysmenorrhœa; but as it tends to cause contraction of the uterine cavity, and therefore rather restrains than encourages the menstrual discharge, it is not a desirable remedy.

I do not wish it to be understood that the above treatment is recommended for the relief of all cases of dysmenorrhœa. When the symptoms indicate an inflamed condition of the internal membrane of the uterus, manifested by the discharge of fibrinous shreds and febrile disturbance of the system, such treatment is of course inadmissible, and the case must be treated according to its indications by local bleeding, by the warm hip-bath, digitalis, saline aperients, etc.

Dysmenorrhœa, as well as leucorrhœa, may be sometimes also caused by the local irritation of ulcers, either within or near the os uteri; and has been successfully treated by the application of the nitrate of silver through the speculum—an instrument which has brought to light local causes of uterine disease, which had long escaped detection by the ordinary means. When, therefore, in dysmenorrhœa, the symptoms are found to resist general methods of cure, and when the intermenstrual mucous discharge from the vagina is ascertained to be purulent and mixed with streaks of blood, it may be fairly inferred that the painful character of the menstrual period is kept up by epithelial ulceration, too far within to be discovered by common observation, and too superficial to be detected by the finger. In such a case, the speculum should be employed without hesitation, in order to decide the question, and allow of the application of such local remedies as may be required. The speculum is undoubtedly a most useful instrument for the diagnosis and treatment of diseases of the distal end of the vagina and the os uteri; but where the symptoms are derived from induration and enlargement of the cervix uteri, the speculum might overlook what the finger will not fail to discover. Such cases are of no uncommon occurrence. The enlargement is most frequently found on the posterior part of the cervix, and in my experience is very difficult of cure, even when it is not of a malignant character. On the other hand, the practice of frequently introducing the speculum, to have ocular proof of the condition of the os uteri, before a fair trial of other remedies has been made, whatever may be the patient's class in society—whether she be in her own dwelling, or in a public institution—whether in a mansion or in a cottage,—ought, in my judgment, to be

considered an abuse of a most useful instrument, and condemned as a demoralizing procedure.

PROFUSE MENSTRUATION, NOSOLOGICALLY CALLED MENORRHAGIA.

An immoderate flow of the catamenia may occur at any period of menstrual life; but it more commonly takes place at its commencement and towards its termination. It may be caused by a plethoric or a debilitated condition of the system; or by some local irritation of the uterus—such as a polypous growth. The two first causes are manifested by the appearance of the patient; the last is ascertained by a digital examination.

Plethora of the system is indicated by a heavy, sanguine and congested aspect; injected conjunctivæ; drowsiness with snoring; vertigo; misty vision; and a full pulse.

Debility, on the contrary, is characterized by an attenuated and anæmic aspect; by a fluttering sensation of the breast; by faintness; sweating upon the slightest exertion; loss of appetite; pale urine; and a small irregular pulse.

It may be proper here to observe, that the menstrual discharge does not appear to be a specific secretion, but in great measure has the character of blood. Dr. Kirkes makes the following remark on the subject: "The menstrual discharge consists of blood effused from the inner surface of the uterus, and mixed with mucus from the uterus, vagina, and external parts of the generative apparatus. Being diluted by this admixture, the menstrual blood coagulates less perfectly than ordinary blood; and the frequent acidity of the vaginal mucus tends still further to diminish its coagulability. This has led to the supposition that the menstrual blood contains an unusually small quantity of fibrine, or none at all. The blood-corpuscles exist in it in their natural state: mixed with them may also be found numerous scales of epithelium derived from the mucous passages along which the discharge flows."*

It is on this account, that profuse and continued catamenial discharge produces such an anæmic condition of the system, which would not be so produced were the discharge a distinct secretion of the uterus, and not an effusion for the most part of the blood itself.

When menorrhagia takes place in plethoric habits, it is manifestly remedial, and ought not to be hastily restrained. In such a case the plethora is the object to be kept in view rather than the discharge; and it will be best treated by a cooling diet, the recumbent position, and the mixture (a).

(a).—Rx Magnesie sulphatis 3vj.
Infusi rosæ comp. 3vss.
Syrupi simplicis 3ss.
Acidi sulphurici diluti 3ss.

Misce. Fiat mistura, cujus capiatur fluiduncia ter quotidie.

But when the discharge has continued for a considerable length of time, producing an anæmic condition and great debility, the indication of cure will clearly be to restrain the uterine flux as speedily as possible by general and local means.

The system may be strengthened by (b).

(b).—Rx Confectionis rosæ 3ss.
Infusi rosæ comp. 3iij.
Decocti cinchonæ 3iij. Misce et cola.
Colaturæ adde,
Acidi sulphurici diluti 3j.
Tincturæ opii ℞ xxx.

Fiat mistura, cujus capiatur quartam partem ter quotidie.

Opium, in menorrhagia from this cause, is a valuable remedy, as it is found to increase the force of circular muscles; whilst henbane, hemlock, and belladonna relax them. Hence it is that the former contracts whilst the latter dilate the iris; and hence, also, the great use of opium in restraining profuse and dangerous hæmorrhage after parturition, by causing contractions of the muscular walls of the uterus.

The bowels, if necessary, should be regulated by gentle aperients, such as the following.

* Hand-book of Physiology, page 608

R Pulveris rhei,
Balsami copaibæ, aa 3 ss.

Misce; et divide in pilulas xij, quarum capiat duas horâ somni pro re natâ.

Turpentine and the secale cornutum have also been found efficacious in restraining menorrhagic discharge.

The best local remedy is the sulphate of alum hip-bath, which may be made in the proportions of twelve ounces of alum to two gallons of water. It may be used daily for about twenty minutes, first tepid, thence gradually reducing it to the normal temperature.

Should the discharge continue unabated, notwithstanding the use of the above remedies, a polypous growth or some morbid condition of the uterus is to be suspected; and the uterus must then be examined.

CASE. An unmarried lady, aged 33, became greatly debilitated and blanched by a profuse flow of the catamenia, which continued every month for about eight days. Various remedies were tried for a considerable time to moderate the discharge; but in vain. As her debility became alarming, the condition of the os uteri was examined; when a small polypus of the size of a nutmeg was found attached by its stem to the internal part of the cervix. This growth was at once removed by ligature, and the menorrhagia ceased.

When profuse red discharge takes place at that period of life when menstruation usually subsides, it is often attributed by unprofessional persons to what is vulgarly termed "a change of life", whilst in truth it is more frequently caused by some organic lesion of the uterus. There is seldom any difficulty in diagnosing such a disease as the cause of uterine discharge. In this case the hæmorrhage is sudden, profuse, clotty and irregular; and when it subsides it is followed by a watery, foul, and offensive discharge. There is almost constant and distressing pain around the pelvic region, extending through the external spermatic nerves half way down the anterior part of the thighs. Sitting upon a hard seat will occasion severe pain of the uterus through the perineum, as also the passage of the contents of the rectum. Besides all this, the mere aspect of the patient, without a vaginal examination, will at once show the wear and tear of carcinomatous disease. Here nothing can be attempted beyond alleviation; and this will best be afforded by opiates, styptics, and rest in the horizontal posture.

Southampton, April 25th, 1853.

CASE OF SCIRRHOUS CONTRACTION OF THE RECTUM; ARTIFICIAL ANUS: DEATH.

By GEORGE MAY, Esq., Surgeon.

CASE. A widow lady, aged 63 years, of peculiarly active habits, enjoying good general health, performing the animal functions naturally without difficulty, and being totally unaware and unsuspecting of local disease, on March 10th, 1853, felt slight irritation of the lower bowel, with desire for relief, but without result. This induced her to take a dose of pills, to which she had been accustomed to resort occasionally. As these pills did not act, she consulted me March 13th, expressing a desire to have a more active aperient. I prescribed ʒiiss of compound senna mixture, to be repeated after six hours, if needful. As these medicines also did not act, and some sickness resulted, a more extended investigation of her symptoms was made. I examined the abdomen with reference to the existence of hernia, but did not discover any. She was now ordered pills with calomel and colocynth, which also occasioned sickness, and failed to act on the bowels. I made another examination of the abdomen, and detected a small tumour in the situation of a right femoral hernia, but without tenderness or pain; the umbilicus also felt slightly full. Not being confident of the existence of hernia, we determined on an immediate operative exploration of these parts. I divided the integuments on the inner side of the femoral

tumour, with a view to reduce the hernia, if present, without opening the sac. The femoral ring was exposed, without discovering hernia, and the tumour lay above it. I now exposed the external abdominal ring by an incision at right angles to the first, and found the tumour to be adipose, and attached by a narrow peduncle to the inguinal canal; but hernia did not exist. The umbilicus was now explored in a similar way, without discovering hernia. Another small swelling was discovered at the outer edge of the right rectus muscle; but we were satisfied, without incision, that it was also adipose. An examination of the lower bowel was made with the œsophageal tube, which passed twenty inches without obstruction, but was slightly grasped as it was withdrawn. She stated that its introduction did not cause pain. About half a pint of water was injected through the tube, and returned unstained by fæces. The sickness which, for the first three or four days, was frequent, and on one occasion of a dark coffee colour (but not at any time fecal), now subsided. The abdomen was generally full, and moderately tympanitic, without special prominence of either portion of the intestinal tube. She suffered occasional pain, with flatulent distension, chiefly in the centre, mid-way between the umbilicus and pubes; but there was no tenderness on pressure. Flatus passed *per anum* occasionally, but no fecal matter. She had a frequent desire for relief by stool, and felt throughout a strong conviction that she should eventually succeed in obtaining it. From the third day of my attendance until her death, the treatment consisted chiefly of calomel and opium, also a dose (gtts. xxv) of Battley's sedative solution occasionally, when she was distressed by painful flatulency. This always gave considerable relief. Various injections, as warm water, gruel, linseed oil, aloe, etc., were also employed. She experienced comfort from the use of warm water, which was exhibited whenever she desired. Her pulse was frequent, ranging from 120 to 140; her countenance was without marked anxiety. She took and retained small quantities of liquid nourishment.

On March 23rd, being the tenth day after my first visit, and probably the fourteenth day since the last fecal evacuation, it became evident that no medicinal means would prove successful; and the constitutional distress having become more urgent, an operation for artificial anus in some portion of the tube above the presumed seat of stricture was proposed. After a delay of thirty-six hours longer, it was performed. Chloroform was not used, being objected to by the patient.

An opening, three inches in length, was made through the integuments, on the right side of the abdomen, over the cæcum; and the latter was opened to about an inch in extent. The edges of the bowel were attached to the integuments by several stitches, and extravasation of blood and fecal matter into the abdominal cavity carefully prevented. The operation was performed without difficulty, and she expressed herself as somewhat relieved. A small quantity of liquid fæces continued to ooze through the wound for three or four hours.

She suffered considerable pain a few hours later, which was relieved by opiates. The exhaustion, which had existed to some extent before the operation, continued to increase; and she died about twenty-eight hours after the operation.

EXAMINATION OF THE BODY, seventeen hours after death. The small intestines were generally but moderately distended. The descending colon was distended with flatus and fæces. A firm stricture from scirrhus carcinomatous deposit existed in the rectum, about six inches from the anus, scarcely permitting the point of the finger to pass within it superiorly. Its extent was about three inches; it was annular, but was chiefly situated in the anterior wall; it was stratiform, and about one inch in thickness; it closely adhered to the fundus of the uterus. The mucous membrane was ulcerated, and about four inches of the tube above the stricture had overlapped the strictured portion, considerably augmenting the obstruction. The ascending and transverse portions of the colon were less distended.

The small intestines, near the wound, were agglutinated by recent peritonitis. No secondary carcinomatous deposits were found in the abdomen, and no other part was examined. Several calculi were found in the gall bladder, and one was impacted in the cystic duct.

REMARKS. The peculiarities of this important case consisted in the absence of premonitory evidence of stricture, in the sudden supervention of symptoms of obstruction, and in the capability of passing an œsophageal tube high up in the bowel without obstruction, and without any complaint of pain, although the mucous membrane was found to be ulcerated. A correct diagnosis was therefore extremely difficult—perhaps impossible. The absence of persisting sickness, and the duration of the symptoms, seemed to justify the inference that obstruction existed in some portion of the large intestine; while the ready passage of the œsophageal tube forbade the presumption of its existence in any part of the left side.

The choice of operation for artificial anus lay between an opening into the cæcum through the loin, external to the peritoneum, or anteriorly through it. The latter was preferred, as giving the opportunity of opening into any part of the intestinal canal, should circumstances require it. The cæcum was found to be moderately distended, and also the ileum at its cæcal termination. The ascending colon was contracted above; an opening was therefore made into the cæcum.

Since the operation for artificial anus was first performed by Pillore, in 1776, forty-eight cases have been recorded; and are embodied in an interesting and valuable communication by Mr. Caesar Hawkins, published in the *Medico-Chirurgical Transactions*, vol. xxxv. From this table, it appears that an opening into the cæcum by Littre's operation on the right side, has been performed four times before the present case; and that all these cases were fatal. The small intestine has been opened twice, both cases being fatal. A similar operation has been performed on the left side, also through the peritoneum, in eight cases, five of which recovered, and three died. I am not aware of any reason, anatomical or otherwise, which can account for these comparative results; and must presume death to have arisen from other causes than injury to the peritoneum.

Had we been able rightly to diagnose this case, an opening in the left loin, if made sufficiently early, would probably have been successful. The existence of cancer would not have barred its chance of success, as is proved by the recorded results of former cases.

I had the satisfaction to be associated in the conduct of this case with Dr. Burnie, of Guildford Street, London, a friend of the patient; and also, at the operations, with my partner Mr. Harrington, and my son.

Reading, April 1853.

CASE OF SIMULTANEOUS DISLOCATION OF BOTH HUMERI.

By C. ROBERT THOMPSON, Esq., Surgeon.

CASE. Mr. K., aged about 62, a tall, well-made, muscular man, but with a constitution much impaired by intemperance, met with the following accident on March 30th.

He had been for some time invalided, but ventured to walk out alone to visit a friend about a mile and a half from his home. He said that he felt inclined to "pitch ahead" more than once on his journey; but managed to reach within a few yards of the door, when he became suddenly giddy, and fell flat on his chest and face, on a hard uneven path. He stated that he felt an utter inability to help himself, or to make an effort to prevent the fall; at the same time, he did not lose consciousness.

Assistance was at hand; and on getting him up, he complained of loss of the use of both arms, and violent pain in

the shoulders; his face was slightly contused, and cut about the nose and brow, and he seemed very faint.

I saw him about an hour after the accident; and, on undressing him, had no difficulty in deciding that both humeri were dislocated: on the right side forwards, the head of the bone making a very perceptible prominence below the clavicle; on the left side directly downwards into the axilla, presenting all the characteristics of that displacement in a very marked manner. I reduced the left dislocation, with the heel in the axilla: the right was more obstinate, but was reduced in the same manner, after a time, by Mr. Rathill, of Westerham, who was so good as to assist me.

The patient complained much for some days of pains about the shoulders and upper part of the chest; but went on quite well, and has recovered the use of both arms.

REMARKS. In considering the cause of this unusual double dislocation, the most evident explanation appeared to be, that the patient endeavoured to save himself by throwing forwards both hands, and the whole stress of the weight of the body coming on the capsules of the joints, they gave way. But he states positively that he had no power at the time to make any effort, and that he fell flat on the chest and face. Moreover, had he fallen with his hands forwards, probably the head of the bone would have been displaced backwards on the dorsum scapulæ, certainly not forwards, as one was, into the subclavicular fossa.

The only way then in which I can attempt to explain the dislocation is, that falling as he did, heavily and suddenly on his chest, with the nervous and muscular energy paralysed for the time either by syncope or a slight apoplectic seizure, the force of the jolt, and the power of gravitation (which would act with particular impetus on the head of the humerus in a man of large prominent chest) were sufficient to dislocate both bones from their normal situation.

In looking for instances of a similar accident, I find mention of six cases in different numbers of the *Lancet* of last year.*

In one case, related by Mr. W. H. Smith, the accident may probably be attributed to the cause I have suggested in my case; the patient falling heavily forwards in a state of helpless intoxication, and both shoulders being found dislocated.

Mr. Greenwood, of Bradford, relates the case of a man, whose shoulders were both displaced by slipping on to his back when intoxicated. Here one arm had been dislocated ten times, the other once before. In this instance, I imagine the concussion of the body was sufficient to dislocate the joints.

Two cases, where this accident was caused by direct force, applied to both shoulders at once, are recorded: one by Sir A. Cooper, of a man who threw himself off a bridge into the river with the arms extended horizontally, and was found afterwards with double dislocation into the axillæ; the other by Mr. C. Webber, whose patient fell between two stacks of timber, so that both arms were struck upwards in his descent.

In the remaining two cases, the dislocations were caused by force at the hands, acting with immense leverage on the shoulder joints.

One is mentioned by Mr. Skey,† of a butcher, who was raising a calf, when it fell backwards over his head; the other by Mr. Thompson, of Brandon, also of a butcher, who was pitched out of a cart, and came head foremost with great force on his hands.

These are the only instances which I have been able to find; but I have not the means at hand of consulting many authorities on surgery.

BIBLIOGRAPHICAL NOTICES.

HOMŒOPATHY: ITS TENETS AND TENDENCIES, THEORETICAL, THEOLOGICAL, AND THERAPEUTICAL. By J. Y. SIMPSON, M.D., F.R.S.E., Professor of Midwifery in the University of Edinburgh, and Physician Accoucheur to the Queen for Scotland. Third edition. 8vo. pp. 292. Edinburgh: 1853.

THIS is an enlarged edition of a former work. It is a complete examination of a hydra-headed system of delusion and swindling, recently and still in vogue. The untenable nature of the homœopathic dogma, the blasphemous character of many of the subsidiary tenets, and the impossibility of the infinitesimal quantities, are elaborately and thoroughly exposed. In every instance, the confuted opinions are fully stated in the exact words of authorized homœopathic writers. Perhaps some members of the medical profession may think that Dr. Simpson has brought an unnecessary amount of logic, truth, and common sense into the field; and that the demolition of homœopathy hardly required to be executed by the unsparing use of such powerful weapons. We are not inclined to take this view of the case. Whatever is worth doing at all, is worth doing well: and it was therefore right in Dr. Simpson, if he undertook it at all, to use his learning and his talents to the best advantage in presenting to the public, to his pupils, and to the profession, a perfect account of the whole subject, in its various aspects of delusion and iniquity. In this he has succeeded. The value of such works in checking delusion, and preventing the quack from levying toll upon popular ignorance, is, we believe, very small; because it is only by disciplined minds that such works can be appreciated and understood. The chief importance of Dr. Simpson's volume lies, therefore, in the fact that it aids in detaching from legitimate medicine the various deceptions and delusions which constitute homœopathy as known among us. To suppress the "hygeian system", the "Thomsonian system", the homœopathic system, or any other system of quackery by law or by argument is impossible; for there is always a very large body in the community who form a ready prey to the specious simplicity of charlatanism, in whatever form it may be brought forward. Dr. Simpson evidently entertains the same views with ourselves on these points.

The following passage is a commentary upon the rules adopted by the different colleges and medical societies with reference to homœopathy.

"It is, perhaps, proper that it should be distinctly explained and understood, that the practitioners of homœopathy, particularly those in Great Britain, have generally sought to derive advantage from the assertion that the doctrines of Hahnemann regarding infinitesimal doses, etc., formed merely additions to and improvements upon that system of medicine, 'which had hitherto occupied the minds of men, and been tested and confirmed by the experience of ages'; and that these doctrines were not fundamentally and entirely opposed to the established system in its principles and practice. Homœopaths fortified the belief of the public in this misconception, by pointing to the fact that they possessed the same medical licenses and degrees, and belonged to the same medical colleges, societies, etc., as the practitioners of legitimate medicine.

"Long, and as I conceive properly, the common law of England and Scotland has been such as to allow British subjects the most perfect freedom as to patronizing or practising any form whatever of medical superstition and pretension; and the late resolutions of our medical corporations and societies were not therefore intended to interfere in any degree with homœopaths continuing to treat all those who applied to them, according to their own peculiar creed. But the resolutions were intended to show that the differences between the doctrines and practices of legitimate physicians, and the doctrines and practices of homœopaths, were so great as to render any farther intercourse and cooperation between them impossible in the conduct of professional matters, and in the duties of professional life. Indeed, Hahnemann himself had long before pronounced precisely a similar opinion regarding the proper relations of homœopaths to legitimate practitioners, and the impossibility

of the disciples of homœopathy countenancing the doctrines and practices of legitimate physicians, or as he opprobriously and foolishly styled them—"allopaths." (p. 2.)

This volume is one which it is impossible to peruse without profit and satisfaction. It is more than a refutation of homœopathy. The general character of medical imposture is illustrated throughout its pages. In particular, it is shown that every form of charlatanism claims the test of experience, and that notwithstanding all that is said about the advanced knowledge of the nineteenth century, the credulity of thousands of men and women, calling themselves educated rises up around us with luxuriant growth, in defiance of indisputable physical laws.

MODERN ADVANCEMENT OF PRACTICAL MEDICINE AND SURGERY: an Inaugural Address to the Medico-Chirurgical Society of Edinburgh. By JAMES Y. SIMPSON, M.D. 8vo. pp. 18. Edinburgh: 1853.

THE author passes before us in rapid and luminous review the advances which have been made during the last fifty or sixty years in morbid anatomy, histological anatomy, pathological chemistry, physical diagnosis, materia medica, operative surgery, and practical medicine.

The following passage graphically depicts what medical science has done for the human race, and encouragingly suggests the path to other fields of victory.

"It is now some two hundred years since Sydenham wrote and practised in London. Consider for a moment what this father of English medicine described as the most fatal diseases in England at that time. Six of the most destructive diseases, or classes of diseases, to human life in that age were, according to Short's mortality bill, plague, ague, dysentery, scurvy, child-birth, and small-pox. These maladies, however, enjoy their fatal pre-eminence no longer. We have banished the plague, which in the olden times often destroyed in London more lives than all other maladies counted together. We have rooted out and modified the ague, so that it is rarely a fatal affection now, while every year it destroyed thousands formerly. Scurvy has almost disappeared from our mortality bills. Dysentery, though still sometimes a fatal disease, is infinitely less common, and infinitely more under medical treatment, than it was at the time of Sydenham. At that date, or in the middle of the seventeenth century, about one in every forty or fifty women delivered in London died of childbirth or its consequences; but gradually, as medical science has advanced, that mortality has decreased, till now not above one in 150 or 200 die. We have in Great Britain about 600,000 deliveries annually, and still above 3000 of the mothers perish in child-birth. If the old mortality, however, of the seventeenth century yet held good, and this department of practice had not greatly progressed and improved, not less than 11,000 or 12,000 maternal lives would now be lost by the present proportion of annual births: the advancements of modern science thus effecting in this item alone a saving of the lives of 7000 or 8000 mothers every year. And as for small-pox—another of the great sources of human death in the days of Sydenham—this fearful and most destructive malady has, as we have just stated, been almost entirely destroyed by the discovery of Jenner. These most formidable and fatal diseases of Sydenham's time sustain the pre-eminence of their formidable and fatal character no longer. And may we not hope that, a couple of centuries hence, the very same fact may hold true of some of those diseases that are at present most destructive and deadly in their effects upon our population? Does not the history of the past suffice to encourage within us a bold belief that perhaps in half a century or a century hence, our present most fatal diseases may, by the advancement of hygienic and medical means, be our most fatal diseases no longer? At the present day we have, according to the registrars' official returns for England and Wales, consumption producing above 50,000 deaths a-year; convulsions above 30,000 deaths; pneumonia and bronchitis above 30,000 deaths a-year; typhus fever and scarlet fever generally above 20,000 deaths each; and measles, whooping-cough, rheumatism, diarrhoea, hydrocephalus, etc., destroying human life among us in still in fearful numbers. These several diseases at the present time as the highest on the roll of destruction that prevail in British practice. For one, I cannot but not but entertain an ardent belief that medicine will devise measures, prophylactic perhaps, rather than

stay the great destruction of human life prevailing amongst us from the first, for example, of these affections, phthisis. Perhaps a more advanced pathology and chemistry may yet ere long furnish us with more enlightened and practical views of pneumonia and other inflammatory disorders than we yet possess, and arm us with more sure and potent medicinal weapons and resources against them. We have, from the experience of the last few years, every reason to hope that the whole class of zymotic diseases will be greatly subdued betimes in intensity and violence, when the investigation of the physical causes predisposing to them, or even actually exciting them, is more fully explicated. If medicine has devised means to arrest the ravages of small-pox, may it not yet devise some means also, by inoculation or otherwise, to arrest the ravages of scarlet fever and measles, of hooping-cough, of typhus fever, and perhaps of the whole class of non-recurrent diseases? And even if we fail to arrest them, we may possibly find out for the varying animal poisons producing these diseases, antidotes as certain as quinine is against the poison of marsh fever."

ATLAS OF THE FORMATION OF THE HUMAN BODY, in the Earliest Stages of its Development: compiled from the Researches of the late PROFESSOR DR. M. P. ERDL. By JOSEPH KAHN, M.D. (Vienna). Illustrated by sixty figures contained in thirteen plates.

DR. KAHN lately exhibited in London and the provinces a very beautiful collection of anatomical models. The work before us contains accurate drawings of those by which he illustrated microscopic embryology, accompanied by short descriptions adapted to the junior student and the non-professional inquirer into the mysterious subject of generation. As an easy introduction to the study of embryology, Dr. Kahn's Atlas will be found useful.

HINTS ON SEA BATHING. By EDWARD D. WALKER, Extra-Urbem Licentiate of the College of Physicians of London. 12mo. pp. 46. Teignmouth: 1853.

This is a tract for sea-bathers. The hints are useful, and interestingly expressed.

PERISCOPIC REVIEW.

MATERIA MEDICA, PHARMACY, AND THERAPEUTICS.

HYDROCHLORATE OF AMMONIA IN CASES OF ENLARGEMENT OF THE PROSTATE GLAND.

M. VANOYE, in the *Annales Médicales de la Flandre Occidentale*, speaks favourably of the use of hydrochlorate of ammonia as an internal remedy in cases of engorgement of the prostate. An abstract of his essay is given in the *Gazette Médicale de Paris* for February 26th, 1853.

In illustration of the effects of this medicine, he relates the two following cases:—

CASE I. A labourer, aged 58, who had several times had gonorrhoea, began in 1847 to experience dysuria, which was at first relieved by palliative remedies; but it soon reappeared in a more intense form. When the patient consulted M. Vanoye, in March 1848, this surgeon convinced himself, by examination with the catheter and *per anum*, that the impediment was caused by enlargement of the prostate, principally of the left lobe. Leeches, baths, rest, etc., gave relief; but the cause of the disorder still continued, in spite of the employment of the usual remedies. M. Vanoye then administered the hydrochlorate of ammonia, as recommended by Fischer. He first gave four *grammes* (one drachm) daily; in eight days he increased the dose to eight *grammes*, and soon afterwards to twelve *grammes*. It was given in a mucilaginous vehicle. As no improvement was produced, the dose was increased to sixteen *grammes* daily (half an ounce); but this gave rise to diarrhoea, anorexia, and some symptoms of scurvy. The prostate, however, had begun to diminish in size; and the patient, although weakened by the effects of the medicine, felt considerably better.

After suspending the use of the remedy for twelve days, M. Vanoye resumed it in doses of eight *grammes* (two drachms) daily. At the end of a month, micturition was performed more easily than it had been for some years; and the prostate was of comparatively insignificant size, and incapable of offering any great impediment to the passage of urine. The patient has since been seen, and continues to enjoy good health. When he indulges in an excess of spirituous liquors, there is dysuria for some days; but this has never yet required any energetic treatment.

CASE II. A man, aged 64, who had had vesical catarrh for two years, consulted M. Vanoye in February 1850. A catheter passed freely through the canal. The symptoms were relieved by injection of tar-water; but, at the end of ten weeks, the patient returned with the same disorder, accompanied by incomplete retention of urine. He had evident enlargement of the prostate. The symptoms being unchecked by injections, the internal use of turpentine, uva ursi, and copaiba, M. Vanoye administered at first two, then four *grammes* of hydrochlorate of ammonia daily: he afterwards increased the dose to eight *grammes*. In six weeks, a miliary symptom appeared, on account of which the use of the medicine was suspended. At this time the patient, whose sufferings had gradually diminished, believed himself cured. The urgent desire for micturition was no longer felt; the urine passed freely; and examination *per anum* showed only slight swelling of the prostate. The treatment, however, was continued for nearly two months. The patient, when recently seen, asserted that, except that he passed urine rather frequently, this function was performed as well as it had been when he was in health.

Since the experiments made by Fischer in 1821, and repeated by several German practitioners, no well authenticated account of the action of hydrochlorate of ammonia in urinary diseases has been published. The conclusions drawn by M. Vanoye do not exceed the legitimate deductions from the two preceding cases; and he is far from attributing to this remedy a sovereign and constant power. On the contrary, he acknowledges that it has once failed, although employed under apparently the most favourable conditions.

The hydrochlorate of ammonia must be given in full doses, and continued for some time. It is best borne by the stomach when given in a mucilaginous vehicle, or combined with a bitter extract. It is also very advantageous to employ tonics, diet of soup, wine, and roast meat.

Independently of the reaction of the digestive canal, there are other symptoms by which it may be ascertained that the system is saturated with the hydrochlorate of ammonia, and that its continued use would be productive of disadvantage. From the cases already observed, it appears that these symptoms are a miliary eruption, profuse sweats, and especially symptoms of a scorbutic character, as sanguineous spots, hæmorrhage, and aphthæ. Fischer asserts that the miliary eruption indicates the necessity of discontinuance, or at least temporary interruption, of the use of the medicine.

BUTTER A SUBSTITUTE FOR COD-LIVER OIL.

The *Union Médicale* for May 3rd, quotes the following from the *Répertoire de Pharmacie*.

Cod-liver oil is an aliment which restores and reconstitutes the tissues: in a word, it is an analeptic medicine, by the aid of which the disorganizing action of tubercle is combated. The only inconvenience attending its use is, that it is sometimes difficult of digestion. In this case, M. TROUSSEAU substitutes with advantage for it, the following compound:—

Fresh butter	3 iv.
Iodide of potassium	gr. ʒ.
Bromide of potassium	gr. iij.
Common salt	3 ss.

This butter is eaten during the day on very thin slices of bread.

ALBUMINATE OF IRON AND SODA.

In the *Bulletino delle Scienze Mediche di Bologna* for Nov. and Dec. 1852, as quoted in the *Dublin Quarterly Journal of Medical Science* for this month, M. A. FABBRI suggests a method of meeting the difficulty often experienced in administering iron in the manner most suitable to the organism, and which has led to its being given by some in the metallic or oxidised state, and by others in compounds with inorganic or organic acids. He recommends the use of a compound of albumen (white of eggs), caustic soda, and sulphate of iron. It is prepared so that each ounce contains about four grains of the albuminate, plus an excess of albumen and soda.

MIDWIFERY AND DISEASES OF WOMEN.

MENSTRUATION DURING THE EARLY MONTHS OF PREGNANCY.—SUPERFETATION.

In the *Monthly Journal of Medical Science* for April 1853, Dr. J. MATTHEWS DUNCAN, after stating the views of authors on the nature of the decidua, says:—

Seiler, C. Weber, and other continental physiologists, were the first to lead the way to correct views of the nature of the decidua. They opposed the opinion of John Hunter and his numerous followers, that it resembled coagulable lymph in

its formation, and described it as a peculiar development of the internal membrane of the uterus. Subsequently, E. Weber, Sharpey, Reid, Goodsir, and others, demonstrated the glandular structure of the decidua; and Dr. Sharpey, in particular, threw much light on the whole subject by his investigations into the anatomy of the corresponding parts in the bitch. It is from 1842, however, when M. Coste communicated to the Academy of Sciences the results of his investigations, that we date the complete remodelling of our views on this subject.

The preparation (figured in the woodcut) beautifully illustrates several points in regard to the decidua.

The decidua reflexa has been opened by a crucial incision, and the four flaps turned aside. The fœtus is seen through the membranes; its superior and inferior extremities are well developed. The cavity of the cervix is filled up with the mucous plug.

The woman from whom this preparation was taken, died from causes quite unconnected with the uterus or its functions. Judging from the development of the fœtus, she had arrived at least at the eighth week of pregnancy. The mucous membrane lining the uterus or the decidua vera, is seen to be of great thickness; that lining the cervix is unchanged. The openings of the cervix uteri, and of the Fallopian tube of the left side, are easily seen; that of the right tube has been destroyed in dissection. The decidua reflexa completely covers the ovum, being a thin layer without glands springing from the decidua vera. The cavity of the uterus is still not closed, there being ample space all around the ovum between the two parts of the decidua, from the os uteri to the tubes.

On examining the uterus of a woman dying during or soon after menstruation, we find the mucous membrane of its cavity vascular, much injected, red in colour, soft and permeated by its numerous tubular follicles, having the appearance of white lines in a cross section. It is, in fact, not capable of being distinguished, except by the minor degree of its evolution, from the decidua of pregnancy. We have thus, at every menstrual period, a nidus prepared for the ovum about to be expelled. The human female, thus, at every menstrual period, passes through the first or initial processes of pregnancy.

Most obstetric authors of repute have with great reason doubted or denied the occasional presence of real menstruation during the latter months of pregnancy; but they have very generally admitted its occurrence, very frequently once, more rarely twice, or thrice, after conception. At the same time, they have felt difficulty in admitting its derivation in any case from its ordinary source, seeing that they believed the uterus to become sealed up by the decidua, or otherwise, immediately

after conception. But I have seen anatomical proof of the possibility of this secretion being derived from the lining membrane of the cavity of the uterus, up till the end, at least, of the second month of pregnancy. It would only be necessary to have the mucous plug in the cervix displaced. Now it is quite possible, nay, probable, that the persistence of this plug may sometimes be even injurious, by retaining the sanious or other fluids (hydropertione) which may accumulate above it to an injurious extent; and there is certainly no reason to think that its displacement should involve the ovum in any danger. My dissections of virgin and unimpregnated uteri have frequently, indeed generally, demonstrated the existence of this firm and adherent plug of mucus in the non-menstrual state. From these considerations, it is manifest that the secretion of the menstrual fluid from its ordinary source, and its subsequent discharge, are in no manner impossible in early pregnancy.

Now menstruation proper is a generally received indication that conception is possible. And there is no reason to believe that this does not hold good of the menstruation occurring in early pregnancy. Physiologists have found no difficulty in admitting the possibility of superfetation during the first few days after conception; or, as Velpeau,* Allen Thomson,† and others, specially point out, till the uterus becomes closed up by the decidua. Of this, the authentic instances of twin-births, where one child has been born black and the other white, in accordance with successive impregnations by black and white males, form incontrovertible illustrations. But the uterus is not closed up till about the third month, and then it is so much

* *Traité complet des Accouch.* (Bruxelles, 1840), p. 444.

† *Cyclop. of Anatomy and Physiology*, vol. II, p. 444.

to think superfetation impossible till this takes place.* The uterus does not become closed, and repeated impregnation is not impossible, till the ovum is so large as to force the decidua reflexa into close and firm opposition to the decidua vera. Up till this time (in the third month), there is a sufficiently free communication between the ovary and the vagina, or between the ova and the semen. Numerous physiologists adduce the plug of viscid cervical mucus as an impediment to impregnation during pregnancy; but frequent examinations have convinced me that this plug is dense and well developed, and apparently impassable in the non-menstruating unimpregnated uterus, and as it does not prevent conception then, so there is no reason to ascribe to it this function in early pregnancy.

Without going over the numerous cases of superfetation which are recorded, it may be stated that this explanation will account for all the authentic cases. For if we suppose that the first child is born prematurely, but within the limits of viability, we thus gain two months; and if impregnation may take place between two and three months after conception, we have thus four or five months of interval accounted for between the births of successive viable infants.

Dr. Duncan's view agrees in the main with that advocated by Dr. Alexander Henry, in a paper on superfetation, published in the *London Journal of Medicine* for December 1849. After citing authorities in proof of the occurrence of menstruation during the early months of pregnancy, Dr. Henry writes as follows:—

Admitting the possibility of menstruation taking place during pregnancy, we may inquire under what circumstances it occurs? Many of those who admit its possibility say, with Dr. Davis (who denies that the fluid is menstrual), that the discharge may be furnished by the vessels of the exterior of the cervix and vagina, which assume a periodical catamenial function. It is probable that many cases are of this kind; and that if the menses flow during the later months of pregnancy, they may arise from the vaginal portion of the uterus; but it is unnecessary to ascribe the flow to an extra-uterine source in all cases. The uterus may furnish it from its inner surface. In cases of double uterus, the unoccupied cornu may furnish the secretion. As for the plug at the os uteri opposing its exit, I do not think this is at all a difficulty; for the secretion may remove an imperfectly formed plug.

The periodical occurrence of the catamenial flow during pregnancy, must be considered as a proof of its being connected with ovarian excitement, and consequently with an aptitude for conception. It evidently obeys the same laws as those which usually regulate the appearance of the menstrual secretion.

It may not even be necessary that obvious menstruation should take place. Some women have become pregnant, though they have never apparently menstruated: and it is very possible that the essential phenomenon of menstruation—ovarian excitement—may be present to such a degree, as to allow the possibility of superfetation, provided that no other impediment exist.

CASE OF DOUBLE UTERUS (UTERUS BICORNIS): TWIN PREGNANCY: PLACENTA PREVIA.

This case is related by Professor HOHL, of Halle, in the *Deutsche Klinik* for January 1st and 8th, 1853.

CASE. J. S. N., aged 30, was admitted on May 5th, 1850, into the Lying-in Hospital at Halle. She had walked thirteen miles before reaching the institution. When admitted, she was exhausted, pale, and suffering from violent cough. She had had hæmorrhage from the uterus. Restoratives and rest in bed were ordered.

On the next day, the following history was obtained. The catamenia had first appeared at seventeen and a half years of age, and had recurred regularly and abundantly until her first pregnancy in 1848. On this occasion, the abdomen was enlarged, and the fetal movements felt, only on the right side. At the full period, she was easily delivered of a female child. In the middle of September 1851, menstruation ceased. She felt fetal movements at the end of January 1852; they were stronger and more frequent than in her previous pregnancy, especially in

the horizontal position. During the first three months of her pregnancy, she had periodically a slight hæmorrhage. This went on increasing, and recurred on April 18th, when she was in the seventh month of gestation, being then accompanied with slight pains in the loins; it was more severe, and lasted three days. In the beginning of May the hæmorrhage returned.

On May 6th, the following was her condition. The abdomen was strongly distended on both sides, but flatter in the middle, and somewhat depressed from the umbilicus to the pubes. Here there was a space, measuring below from an inch to an inch and a half, above rather more than four inches in breadth, where percussion gave a clear sound; while there was dullness on each side in a direction from below upwards and outwards. The uterus was felt above the horizontal rami of the pubic bones; and, about an inch or an inch and a half above the pubes, at the point where the clear intestine-sound was heard, it divided into two parts, of which the right was somewhat larger than the left. Each portion was convex on the inner, and somewhat concave on the outer border. Each division reached above the umbilical region, and in each the parts of a child could be felt; in each the sound of the fetal heart was heard, rather higher than usual; and above each horizontal ramus of the pubic bones, the placental sound was heard, somewhat higher on the left side than on the right.

On internal examination, the vagina and pelvis were found normal. The spaces between the cervix uteri and vagina were deeper than usual, resembling two blind canals. The cervix uteri was short, and much larger in circumference than is common; it was of equal width above and below, both externally and internally. The os was open to the extent of an inch; and at the upper part there was an opening on each side, of about half an inch. A placenta lay at the orifice on the right side; it was detached from the uterus in a semicircular direction from before to the right and backwards, as high as the finger could reach. On the left side, also, a placenta hung from the os uteri, and had to be pushed up before the finger could reach the point where the internal orifices met. At this part, the union of the inner walls of the horns of the uterus was felt.

Some hæmorrhage followed the examination, but gradually ceased, and did not recur until next morning, being accompanied with slight pain and cramp. The external os was distensible; the internal orifices, though more distended, were unyielding.

As there was extensive separation of the placenta on the right side, and it was feared that, if delivery were first attempted in the left division, it would become entirely separated, and be expelled before the child, whose heart could still be heard, delivery was first effected, without much difficulty, in the right horn. This division contracted at once, while the left remained unchanged. During the short period during which the patient was allowed to rest, the utero-placental murmur, which had disappeared on the right side, was heard on the left. On the left side, also, delivery was easily performed. The placenta was adherent to the outer wall, and had to be removed. Both children were males, of equal size, weighing each three pounds. The first was apparently dead: it breathed a few times, and died. The second was also dead.

The patient was attacked with pleurisy of the right side on the sixth day; it was followed by effusion. She recovered slowly, and was discharged cured on June 23rd.

In the early period after labour, the correctness of the diagnosis which had been formed—that the case was one of *uterus bicornis*—was confirmed by manual examination, palpation, and percussion, as well as by the introduction of the uterine sound. In fact, the character of the uterus was better marked during this period than it had been during pregnancy. During the return of the uterus to its unimpregnated size, the gradual divergence of the horns could be felt at the upper part. The point where the horns met was scarcely an inch above the orifice; and while the internal orifices slowly closed, the os uteri remained open.

Arnoldi (*Casper's Wochenschrift*, 1839, p. 834) relates a case of double uterus, in which the patient had placenta prævia in three pregnancies. In the third, the midwife found an arm presenting, and Arnoldi was called in six hours after. The patient died.

Meckel, Carus, and Rokitsky have asserted pregnancy in a double uterus to be generally unfavourable, from abortion, hæmorrhage, or rupture of the uterus. But if the cases of pregnancy in double uterus be examined, it will be found that women have borne from three to fourteen children; and the causes of death in fatal cases have been those which occur when the uterus is single. Carus relates a case in which the woman died on the twenty-first day; but she had uterine phlebitis.

* It is now established, chiefly by the researches of Pouchet, Raciborski, and Bischoff, that a mature ovum is ordinarily expelled after every menstrual period. On the occurrence of pregnancy, the maturation of ova in the Graafian vesicles, and their expulsion, are generally arrested till the end of the period of suckling. But this is not invariably the case. In the human female, the sign of ovulation being about to take place is the occurrence of menstruation. The discharge of the menstrual fluid necessarily displaces the mucous plug in the cervix of the pregnant as of the unimpregnated uterus, and thus clears a passage for the conjunction of the ovum of the female with the spermatozoon of the male.

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

SATURDAY, MARCH 26TH, 1853.

FORBES WINSLOW, M.D., President, in the Chair.

FIBRINOUS COAGULA EXPELLED AT THE MENSTRUAL PERIODS.

BY EDWARDS CRISP, M.D.

A delicate woman, aged 30, who had been twice pregnant, had leucorrhœa and vaginal discharge, accompanied with pain in the back and loins, and tenderness in the uterine and ovarian regions, sometimes with bearing-down sensations. Menstruation was painful, and often attended with expulsive efforts. Occasionally, clots of coloured fibrin, about the size of almonds, were discharged. Under the microscope, these bodies were found to consist of a net-work of fibrin, in the meshes of which were stellate or granular red corpuscles. Dr. Bence Jones and Dr. Tyler Smith had exhibited to the Pathological Society similar bodies. In Dr. Smith's case, the mass was mostly composed of epithelium.

PROLAPSUS OF THE ANTERIOR WALL OF THE VAGINA AND BLADDER; AND A NEW OPERATION FOR ITS CURE. BY L. B. BROWN, ESQ.

This disease is not uncommon, and is sometimes mistaken for prolapsus uteri; it is generally met with in females who have passed the middle age, and have borne children.

There are three modifications of prolapsus of the vagina, viz.: prolapse of the anterior or posterior parietes of the vagina, or of its entire circumference: the two first are connected with other organs; the third occurs independently. Prolapsus of the anterior parietes of the vagina and of the bladder, or, as it is also called, prolapsus vesicæ, or vaginal cystocele, was the subject of Mr. Brown's paper. Here the vagina, or more properly speaking, the inner membrane only, becomes relaxed, generally from repeated child-bearing; and the urine, having been allowed to accumulate, distends the bladder, and, pushing it downwards, protrudes the yielding vagina. Every fresh accumulation increases the distension, and complete prolapse is the result.

Symptoms. The patient complains of weight and bearing down, and sensations of dragging in the lower part of the abdomen, unpleasantness in walking, and more or less dysuria,—the bladder having, to a great degree, lost its power of contraction. Some patients are obliged to replace the bladder before they can evacuate the urine. On examination, a soft, elastic, fluctuating tumour is felt at the orifice of the vagina; it is of a red or bluish-red colour; and this tumour can be greatly diminished by catheterism; the finger can be passed into the vagina below the tumour, and the os uteri can be felt behind, nearly in its natural situation. The surface of the tumour, when distended, is smooth, moist, and shining; but, when the bladder is empty, it is thrown into transverse folds. There is always very considerable mucous discharge, which is exceedingly irritating to the labia and soft parts; and there is sometimes a very distressing irritability of the bladder, and the urine, when passed, is fetid, and contains muchropy mucous. This arises from a small portion of the urine being always left in the bladder, and, consequently, decomposition of that secretion. This subject has been lately dwelt on in an excellent paper, by Dr. Golding Bird, in the *Medical Times and Gazette*, Jan 1st of this year, headed, "Remarks on Prolapsus of the Anterior Wall of the Vagina, as an Occasional Cause of Fetid Phosphatic Mucous Urine."

This condition may be easily distinguished from prolapsus of the uterus; it is soft and yielding to the touch, and on introducing the catheter, the point will be felt through the walls of the tumour, towards the anus; and, on passing the finger upwards, the os uteri can be felt in its natural position; it can also be distinguished easily from prolapsus of the posterior wall of the vagina, or rectocele, or from inversion of the uterus; that condition preventing the passing of the finger into the vagina at all.

Treatment. This will depend on the extent and duration of the prolapsus. If it be of recent date, and occurring in young females, the treatment should be frequent catheterism, recumbent posture, astringent injections within the vagina, such as alum, oak-bark, infusion of galls, sulphate of iron, cold water, etc., or keeping a bent metallic catheter constantly in the bladder, to which is attached an elastic bag, so that the bladder is constantly empty, and, at the same time, keeping a sponge tent within the vagina, so as to uphold the bladder. Mr. Brown had

under his care a young lady of twenty-four, the mother of two children, who came up from the country, on account of supposed prolapsus of the womb. This patient was considerably improved by the above-mentioned treatment.

If, however, the prolapsus be of long standing, and occur in females beyond the period of child-bearing, the treatment should be more severe and radical. Some recommend plugging the vagina with pessaries, made especially for this condition. These, however, frequently produce much irritation, and hence the necessity for a surgical procedure. It has been recommended to remove a triangular slip of the mucous membrane, the base being towards the orifice of the vagina, and bringing the edges together by sutures, thus contracting the calibre of the vagina. Others recommend the use of the actual cautery so as to produce a slough, and subsequent cicatrization. M. Jobert, of Paris, encloses within two curved transverse lines, an oval space, more or less considerable, in the posterior surface of the vagina, by means of caustic, so as to form an isolated spot, repeating the application of the caustic till the mucous membrane is destroyed. He then pares the edges with scissors or a bistoury, draws them together, and maintains them in apposition by means of straight needles (the points of which are removed) and a twisted suture. He operated thus on a patient in July 23, 1838, and on two others subsequently, with success.

Mr. Brown proceeded to show the results of a new operation which he had devised for this condition, and related the following case in illustration.

CASE. Martha Triggs, aged 52, had had ten children. She was admitted into St. Mary's Hospital, February 14, 1853, suffering from severe prolapsus of the vagina and bladder, which first began to trouble her nine years ago, after her last child. On the least exertion of walking, or standing even, or coughing in the recumbent position, the tumour came down and protruded through the external orifice of the vagina, to the size of a large fist. On lifting up this tumour, when so extruded, there were seen on the under and posterior surface of the os-uteri, which was dragged down by the vagina, two or three ulcerated spots produced by friction against the posterior walls of the vagina. The patient could, when reclining on her back, replace the tumour. She had a cough from chronic bronchitis, which she generally had in winter, complained of feeling weak, and her appetite was capricious.

This patient being a servant in place, suffered greatly from her condition, and was obliged always to wear a bandage or napkin to prevent the extrusion of the tumour; and this very support, by the friction and heat, rather increased than diminished the suffering. Her spirits were depressed, and the poor woman became an object of great pity and commiseration. Mr. Clarke, of Gerard Street, recommended her to place herself under the care of Mr. Brown.

a, meatus; b, catheter introduced and seen by dotted lines of tumour.

* Vide ASSOCIATION MEDICAL JOURNAL for February 18th, p. 164.

Operation. The patient having been prepared, by emptying the bowels, was on February 15th placed under the influence of chloroform, and then put in the position for lithotomy, each leg being held by an assistant, a third assistant holding up the tumour with Jobert's bent speculum, and pressing it under the pubis in its natural position. A piece of mucous membrane, about one and a quarter inch long and three quarters of an inch broad, was dissected off longitudinally, just within the lips of the vagina. The upper edge of the denuded part being on a level with the meatus urinarius, the edges were drawn together by three interrupted sutures, this being repeated on the other

a, clitoris; b, meatus; c c, lateral incision; d, entrance of vagina; e e, horns of perineal incision; f f, perineal sutures; h, rectum denuded of its vaginal (mucous?) covering; g g, four points of interrupted sutures.

side of the vagina. The next stage of the operation consisted in dissecting off the mucous membrane laterally and posteriorly in the shape of a horse-shoe, the upper edge of the shoe commencing half an inch below the lateral points of denudation, taking care to remove all the mucous membrane up to the edge of the vagina where the skin joined it. Two deep sutures

c c, lateral interrupted sutures; d, orifice of vagina; e e, quill sutures; g, interrupted perineal sutures.

of twine were then introduced about an inch from the margin of the left side of the vagina, and brought out at the inner edge of the denuded surface of one side, and introduced at the inner edge of the other denuded side, and brought out an inch from the margin of the right side of the vagina, thus bringing the two denuded surfaces together, and keeping them so by means of quills, as in the operation for ruptured perineum. The edges of the new perineum were then brought together by interrupted sutures, and the patient placed in bed on a water-cushion; two grains of opium were given directly, and one grain every six hours; simple water dressing applied to the parts; beef-tea and wine for diet. A bent metallic catheter was introduced in the bladder, to which was attached an elastic bag to catch the urine. By this means, the bladder was constantly kept empty. This patient progressed satisfactorily from day to day without a single bad symptom; and on the 22nd, the deep sutures were removed, and the parts found firmly united. The lateral interrupted sutures were gradually removed, and firm union found to have resulted.

February 26th. The deep union was perfectly sound, about three-quarters of an inch thick, the lateral wounds well contracted; the tumour could not be brought down by coughing.

March 8th. The parts were all firmly healed; the patient was much improved in health, with a very cheerful aspect of countenance. She could walk about without inconvenience, and no amount of exertion produced any prolapse. She could empty her bladder with comfort; and all the leucorrhœal discharge, which was so distressing before the operation, had entirely subsided; the offensive smell of the urine had also disappeared. On passing the finger into the vagina, the os uteri could be felt easily in its normal position, and the ulcerated spots which formerly existed on its surface are healed.

On the 10th, she was discharged cured, and resumed her duties as domestic servant.

a, clitoris; b, meatus; c c, lateral vaginal sutures; d, orifice of vagina; e e, perineal sutures; f, new perineum; g, true clito.

REMARKS. The object sought in this operation was the contraction of the calibre of the vagina, which, as may be imagined, was exceedingly enlarged and flabby. The first step of the operation was the contraction of the vagina laterally, so as to prevent the tumour from falling down from above; the second step of the operation was for the purpose of contracting the vagina posteriorly as well as laterally; and, finally, adding to the extent of the perineum, by contracting the orifice of the vagina at least two-thirds, so that, should the prolapse not be restrained by the lateral contractions, it could not extrude beyond the orifice of the vagina, but must necessarily fall upon the new perineum. As was proved by the result, all the objects

sought had been fully attained; and it was scarcely possible to imagine a more satisfactory result from any operative procedure. It will also be observed, that the benefits derived from this operation for vaginal cystocele, will be equally, if not more applicable to vaginal rectocele, as well as to prolapsus of the entire vagina, and also, with some slight modifications, as to the denudation of the mucous membrane, to prolapsus uteri.

DIPHTHERITIC EXUDATION CONFINED TO THE LARYNX.

BY W. H. WILLSHIRE, M.D.

Dr. WILLSHIRE exhibited the larynx and trachea of a child who had died of croup. The exudation was confined to the larynx: there was some tracheitis. Permission could not be obtained to examine the lungs; but during life they had seemed healthy. He thought that, under favourable hygienic circumstances, tracheotomy might have been successfully performed.

DELIRIUM TREMENS. BY W. CAMPS, M.D.

Dr. CAMPS, referring to the diversity of opinion among authors as to the treatment of delirium tremens, believed that this arose from phenomena having been described under this name, which were indeed similar, but which arose from different causes, and required very different modes of treatment. By the term delirium tremens, he meant those symptoms which occurred in persons long addicted to the abuse of intoxicating liquors, which acted on the nervous system, probably through the blood. The principal symptoms were delirium and tremor; the former being most constant. The disease was divisible into three stages. In the first stage, there were lowness of the pulse; coldness and clamminess of the hands and feet; general debility; diminished temperature; giddiness; nausea (sometimes vomiting); the bowels sometimes relaxed, sometimes constipated; nervous tremors of the hands and tongue; depression of spirits; frequent sighing; anxiety of countenance; restless slumbers. In the second stage, the symptoms were increased: the countenance was wild; the patient was troubled with mental and optical delusions, imagining the presence of things round his bed; he was restless and talkative, especially on the objects of his delirium; the temperature of the body might be increased, while that of the extremities continued low; the tongue was coated, moist, and tremulous; the pulse mostly frequent; the urine scanty; the patient would be free from pain, and in answer to inquiries, would frequently reply that he was "quite well". In the third stage, if the case were about to terminate favourably, there was a disposition to sleep, which was often long and critical. In fatal cases, the symptoms increased in violence: the patient struggled violently; and the depression of the nervous and muscular power became increased, attended with low delirium. Death sometimes occurred during convulsions; sometimes was preceded by a diminution of the general symptoms.

In the treatment, general blood-letting was inadmissible. Local depletion by leeches, or cupping, might be sometimes useful. Emetics might be of service in some cases; and an important indication was to attend to the secretions. Dr. Camps referred to several cases which had been successfully treated with chloroform.

Dr. SEMPLE thought that the author of the paper had made a clear subject obscure. He believed delirium tremens to be a well marked disease; and that some cases described under this name, especially one described by Dr. Pratt, of Baltimore, in the *Amer. Journ. of Med. Science* for Jan. 1852, were really cases of ferocious mania, very different from the quiet bustling delirium in the disease under consideration. Delirium tremens was evidently a disease of irritation; it arose from drink, and also from the influence of depressing psychical or other agencies, as despondency, sudden vicissitudes of fortune, etc. In the treatment, the use of bleeding and leeches was absurd: we must employ opium, or morphia, and stimulants.

Mr. WEEDEN COOKE had administered chloroform by inhalation successfully in several cases; and would henceforward at once proceed to its use.

Dr. BOON HAYES had treated five cases of delirium tremens from laudanum drinking, which is frequently practised in large manufacturing towns to the extent of an ounce or an ounce and a half daily. These cases are most difficult to treat; and yet laudanum must be given if any success is expected. He had also seen cases arising from the abuse of tobacco: as in sailors, who would fill a teapot, and smoke through the spout. He had seen a dry tongue from the outset in delirium tremens. In cases where the patient showed a tendency to injure himself or others, he might be overawed. In the use of chloroform, precaution was necessary, on account of the frequent flabby condition of the heart, as shown by *post mortem* examinations of cases

of delirium tremens. He was, however, not afraid to give chloroform, and had seen it used successfully.

Dr. RADCLIFFE alluded to the sensibility of patients to external influences. A less amount of stimulants could be borne at morning than at night; less in the summer than in the winter. Under these circumstances, twelve hours might produce a difference involving a change from a moist to a dry tongue. He had seen two cases in which chloroform had been given in half-drachm doses, frequently repeated, without opium.

The PRESIDENT, Dr. RYAN, Dr. WINN, and Mr. BULLOCK, briefly addressed the Society on the subject of Dr. Camps' paper.

SATURDAY, APRIL 2ND, 1853.

TYLER SMITH, M.D., Vice-President, in the Chair.

CASE OF MONSTROUS BIRTH: FUNIS WITHOUT UMBILICAL VEIN. BY W. C. DENDY, ESQ.

Mr. DENDY exhibited drawings illustrative of a monstrous fœtus, of which a lady of highly nervous temperament had been delivered on the preceding Monday. There was an enormous gush of liquor amnii; the fœtus was born in half an hour, cried for three or four seconds, and died. It was apparently of the seventh or eighth month. The head was a specimen of the class cat's-head (*katzenkopf* of the Germans); it was thrown back, so that the face looked upwards. From the vertex to the lumbar region extended a red bloody fungous mass, with slight disposition to the formation of a spine. The abdomen felt distended and hard; when it was open, it was found almost entirely filled with the liver; the small intestines being like cords. The anus was a mere slit, without any trace of muscular structure. The funis, of which Mr. Dendy exhibited a portion, appeared to contain no vein. An umbilical vein could not be traced to the liver. A minute examination could not be obtained.

With regard to the question, how, under such circumstances, the fœtus could have been nourished, Mr. Dendy was inclined to believe that this must have been effected by means of the liquor amnii; and suggested that the great quantity of this fluid might have been a compensatory arrangement.

EPITHELIAL CANCER OF THE HAND IN A MAN SIXTY-EIGHT YEARS OF AGE: AMPUTATION: RECOVERY. BY WEEDEN COOKE, ESQ.

The patient, a tall, well-built agricultural labourer, came under Mr. COOKE's care in the Cancer Hospital, suffering from epithelial cancer extending over nearly the whole of the back of the hand, attended with ulceration and profuse purulent discharge. The arm was amputated three inches below the elbow. The case went on well for a week, when inflammation of the stump set in, accompanied with separation of the flaps. At the same time, phlebitis—which Mr. Cooke attributed to the tying of a vein during the operation—appeared in the right leg and foot; but this subsided in a fortnight. The treatment consisted in generous diet, with porter, and cinchona with acids. The stump was healed in a month. Three months after the operation, the stump was looking healthy, and there was only some weakness of the leg.

Mr. Cooke remarked on the tolerance of operations in old persons, some of whom appear to have more vigour at seventy years of age than others have at forty. Such subjects, as a rule, must be well supported and carefully watched; while in the young the inflammation and fever would require to be controlled by antiphlogistics.

THE IMPROPRIETY OF PERFORMING TRACHEOTOMY IN CASES OF EPILEPSY. BY C. B. RADCLIFFE, M.D.

Dr. RADCLIFFE read and commented on the histories of six patients in whom tracheotomy had been performed for the relief of epilepsy, in accordance with the suggestion of Dr. Marshall Hall; and also referred to a case mentioned in *Schmidt's Jahrbücher*, in which a fistulous opening existed in the trachea, from an attempt at suicide made by an epileptic patient. In this case, the fits were equally frequent and violent, whether the aperture were closed or open.

One of the patients, whose case has been related by Mr. Anderson, had died in an attack of epilepsy. On *post mortem* examination, there were found some osteophytic growths on the skull, much congestion of the vessels of the scalp and brain; collapse of the lungs; and the heart was full of blood, and surrounded with fat. Before death, the fits had been more severe than usual.

In some of the cases, the relief after operation was attributable to the occurrence of bronchitis or fever; and it might have been nothing more than the freedom of the

for a time, which previously existed. Epileptic fits are often absent for a time without obvious cause. In six out of the seven cases referred to, the attacks had returned.

Dr. Radcliffe did not believe that there was any proof of the existence of laryngismus. There was no stridulous inspiration following the restoration of the power of breathing, which ought to occur. The laryngismus stridulus of children showed that closure of the larynx might occur without the production of convulsions. It was doubtful, also, whether laryngismus could occur in the adult, on account of the change in the anatomical structure of the parts concerned.

Dr. R. BARNES said that, in the fatal case alluded to by Dr. Radcliffe, a portion of the heart had been found by Dr. Jenner to be in a state of fatty degeneration. Dr. Marshall Hall had not recommended tracheotomy as a cure for epilepsy, but as a means of relieving a symptom which occurred in epilepsy and other diseases. It was not fair to suppose that Dr. Hall had asserted laryngismus to exist in all cases: the recurrence of the fits after operation showed that there was some other cause.

Dr. TYLER SMITH said, that stridulous inspiration would not be expected to occur as in infants. Perhaps, however, the peculiar cry attending epilepsy, and the hissing noise in puerperal convulsions, were of this nature. Lividity of the face, which had been referred to by Dr. Radcliffe, might be produced from other causes than laryngismus—by spasms of the muscles of the neck.

Mr. DENDY was unfavourable to the performance of tracheotomy: the constitutional treatment was the chief point to be attended to.

Mr. HENRY THOMPSON referred to a case on which he had operated three months ago. On visiting the patient this day, he for the first time witnessed him in an epileptic fit. There was loss of consciousness, and slight convulsions; but the patient had recovered in ten minutes. Previously to the operation, coma used to continue for four or six hours. The patient was formerly in a state approaching idiocy; but his countenance had become much improved.

SATURDAY, APRIL 9TH, 1853.

FORBES WINSLOW, M.D., President, in the Chair.

CHRONIC RHEUMATIC ARTHRITIS. BY EDWIN CANTON, ESQ.

This disease affected both the small and the large joints, producing deformity and impairment of functions. It had also been observed in the articulation of the lower jaw, impairing mastication and speech; and in the spine, producing deformity, and interfering with the functions of the viscera. In the joints, exostoses were formed, and ossific deposits in the tendons, irritating the nerves, and impeding motion. It was possible that the ossicles of the ear might be affected. According to Dr. Fuller, the disease attacked weak or unhealthy subjects, or robust persons who have been enfeebled by disease. No age or sex was free; but it mostly occurred from the age of thirty-five upwards. In the female sex, it frequently occurred in connexion with suppressed menstruation.

The morbid appearances were loss of the articular cartilages, and denseness and porcellaneous structure of the bones. This was formerly thought to be due to new deposit; but Mr. Quekett had shown that the extremities of the Haversian canals became filled up and polished by friction. The interarticular ligaments were largely absorbed; and the fringes of synovial membrane much hypertrophied, becoming villous, shaggy, and vascular. Loose bodies, either free or pedunculated, were often present in the joints. The round end of the bone was often expanded, and its socket spread out in proportion; and both were surrounded by irregular osseous growths. The ligaments were partly absorbed, and partly hypertrophied; and the muscles of the limb were atrophied, and often in a state of fatty degeneration. The great distinction between this chronic rheumatic arthritis and inflammation lay in the deposition of bone, as well as removal, in the former disease.

The symptoms were dull, heavy, wearisome pain, stiffness, and impaired motion. The pain was most severe at night; the stiffness in the morning. There was no redness nor heat; but the joint slowly enlarged. Pressure produced no pain; but, as the disease advanced, rotation of the limb gave rise to pain, and was attended with a grating sound, from removal of the cartilages. There was little or no constitutional reaction; the bowels were generally costive. Ulceration, suppuration, or ankylosis, did not occur in the affected joints.

An attack sometimes appeared referrible to violence; and such instances, occurring in the hip-joint, had often, without doubt, given rise to unjust impeachment of the skill of the surgeon for not detecting an intracapsular fracture of the neck of the bone. The case of the late Mr. Matthews, the comedian, related by Mr. (now Sir William) Snow Harris at the meeting of the British Association in 1836, was adduced in example.

Again, a patient already labouring under chronic rheumatic arthritis, may, from injury, have symptoms closely resembling those of fracture of the neck of the femur within the capsule.

Errors of diagnosis, Mr. Canton believed, were more frequently committed in the shoulder-joint, where dislocation upwards was, by some writers, as Mr. Fergusson, said to be common. In these cases, the intra-articular tendon of the biceps muscle was lost, and the head of the bone was hence drawn up against the acromion. Mr. Gregory Smith and Mr. Curling had described alleged cases of dislocation of the joint upwards; but had subsequently admitted the justice of Mr. Canton's explanation.

The indications of treatment were, 1, to correct the faulty state of the assimilating function; 2, to attend to the excretory organs; 3, to employ means to remove and arrest morbid deposits. Imperfect assimilation being the *fons et origo mali*, the diet must be attended to. Blue pill, colchicum, and taraxacum, must be given to improve the function of the liver; and the skin and kidneys must be acted on. Bitter infusions, iron, iodide of potassium, and quinine, should be employed. Local applications, as blisters, dry cupping, and the establishment of discharge in the neighbourhood of the joint, should be more employed than they are at present.

Mr. PILCHER had observed cases of apparent dislocation of the shoulder-joint in old women, and referred them to over-use of the limb and imperfect nourishment. He referred also to the occurrence of pain in the shoulder in persons apparently in health, and without any other indication of rheumatism. It might last for weeks or for years—even through life; and sometimes it subsided in consequence of, sometimes without, treatment.

Dr. OGIER WARD inquired whether Mr. Canton had in these cases found deposits, as in gouty subjects.

Dr. FULLER believed that many cases of enlarged joint could not be referred to rheumatic arthritis, although after death there was no difference in the appearances when rheumatism had previously existed, and when it had been absent. In the treatment, local applications were too much neglected. He had found ointment of iodide of potassium, or of biniodide of mercury, very useful. He had ascribed these cases to defective excretions, as contrasted with those arising from excessive formation of morbid matter. The tongue is often clean, the urine of low specific gravity, and the secretions generally defective; and we must improve the general health, and then stimulate the excretory organs.

Mr. RICHARDSON suggested that the dyspepsia, instead of acting as a cause of the disease, might rather be an effect of the incapacity for exercise resulting from rheumatism.

Mr. ROBINSON recommended attention to the diathesis of the patients in whom rheumatic arthritis occurred. In the phosphatic diathesis, there was great proneness to osseous deposits. The treatment was very difficult, because the disease may have existed for years before revealing its presence by pain. Besides, patients did not often allow sufficient time for treatment to have a chance of doing good.

Dr. RADCLIFFE had found attention to hygienic rules of great service. He had seen several cases relieved by being removed to a light and airy apartment.

Dr. DANIELL had found the most intractable cases of rheumatism in the Bath Hospital to be those which had previously been treated with colchicum and calomel. He had observed great benefit produced by the external application of equal parts of wine of colchicum and compound tincture of camphor.

Mr. CANTON had in all cases found evidence of rheumatic disease in more than one joint. He had not found gouty deposits; but the deposits in the joints and tendons might be their analogues. In intracapsular fracture, there was no change in the head of the bone; and this would in examination of specimens distinguish this injury from a case of rheumatic arthritis.

EPIDEMIOLOGICAL SOCIETY.

JAMES BIRD, M.D., in the Chair.

COMPARATIVE MORTALITY OF LARGE TOWNS AND RURAL DISTRICTS,
AND THE CAUSES BY WHICH IT IS INFLUENCED.

BY JOHN SNOW, M.D.

The shorter average duration of life in large towns, as compared with rural districts, depends on the greater mortality in early childhood, and the smaller number of adults who attain to old age. In Liverpool and Manchester, half the children born die before they are five years of age, the numbers being 52 and 51 per cent. In Birmingham, 48 per cent. of the deaths occur before this age, and in London rather more than 40 per cent.; but in Wiltshire and Surrey only 31 per cent. The greatest number of deaths in any decennial period after the age of five occur, in Surrey, from 65 to 75 in males, and from 75 to 85 in females. In Manchester, Liverpool, and Sheffield, the highest mortality after early childhood is from 35 to 45 in males, and from 25 to 35 in females, or forty years earlier than in the same sex in London. In Leeds, Blackburn, Preston, Stockport, Macclesfield, and some other towns in which textile fabrics are manufactured, the greatest mortality in both sexes, after infancy is passed, occurs from 15 to 25; although in two registration districts, not more than twenty miles from Leeds, the highest mortality in both sexes is from 75 to 85, or sixty years later than in these towns. In London, however, the mortality, at the period immediately succeeding to puberty, is lower even than in the rural districts, more especially in the female sex. This is shown by the tables suspended in the room, which are compiled from the Ninth Annual Report of the Registrar General, and exhibit the deaths in London and Surrey at different ages, in relation to the deaths at all ages to the whole population, and also to the numbers living at each of the ages specified. On comparing some of the worst districts of London, such as St. Giles' and Clerkenwell, with the more distant and rural part of Surrey, the advantage of the town over the country in the small number of deaths at this period of life is more striking. In St. Giles', the annual mortality in the seven years 1838 to 1844, between the ages of 15 and 25, was 50 males and 68 females to 10,000 of each sex living at that period of life, whilst in the Guildford district the numbers were 77 males and 90 females.

On examining the Tenth Annual Report of the Registrar General, all the chief diseases of infancy are found to be more fatal in London than in the adjoining rural districts. Convulsions, hydrocephalus, and diarrhoea, probably owe their greater fatality to improper food and general treatment, whilst the constant presence of various infectious diseases in London increases the mortality by affecting the children at an earlier average age than in the country, where they pay only occasional visits, and thus enable many of the children to escape till a later period, when certain of them, as whooping cough and measles, are hardly ever fatal. A proof of the frequently later attacks of these diseases in the country, is the fact that the mortality from scarlet fever in the South Midland district, from the age of 10 to 20, is much higher than in London, although under 5 years, when the chief mortality occurs, it is greatest in London.

The diseases which cause the mortality of the rural districts to exceed that of London, from fifteen to twenty-five years of age, are phthisis and typhus, which are more fatal at this period of life in the country than in London. Typhus indeed is more fatal at all ages, and in both sexes, and phthisis is much more fatal in the female sex, in whom it occurs also at an earlier period of life than in London. The probable cause of the great fatality of phthisis amongst young females in the rural districts is deficient nourishment, consequent on the difficulty of obtaining employment. Typhoid fever is probably less fatal in London than in the country, on account of the numbers who gain an immunity from it in after life, by passing through it in childhood, when it is less fatal, and generally goes by the name of infantile remittent. It is chiefly to phthisis that the great mortality of both sexes between the ages of fifteen and twenty-five in certain manufacturing towns is due.

The above circumstances show that the high mortality which prevails in most large towns is caused more by the habits and occupations of the people, than by the mere fact of their living in towns. Dr. James Bird, Mr. Pilcher, Mr. Walsh, Dr. Chowne, Dr. Camps, Dr. Burford Carhill, and the author, took part in a discussion which followed the reading of the paper.

ASSOCIATION INTELLIGENCE.

SOUTH WESTERN BRANCH.

On Tuesday, April 26th, a meeting was held at the Devon and Exeter Hospital, for the purpose of receiving the report of the committee appointed by the South Western Branch of the Provincial Medical and Surgical Association, to confer with the promoters of the Medical Reform Bill. The attendance of the profession generally had been requested; and, accordingly, a considerable number of gentlemen interested in the measure were present.

Mr. DE LA GARDE having been called to the chair, said:—I have convened this meeting with the entire concurrence of the committee appointed by you at our last annual meeting, to confer with the central committee, who have taken in hand a Bill for Medical Reform. I have called you together reluctantly, because I know with how great a sacrifice of feeling each individual of our profession quits for a few hours the field of his practice; and I fear you will think I have done so on insufficient grounds, should you judge from the little you may have collected from the organ of the Association. You have, doubtless, seen short editorial notes in our Journal, which, I perceive, has very properly ceased to call itself provincial, leading you to this conclusion, that cordiality alone prevails between ourselves and the central committee. Our suggestions have been so gracefully received, our objections so blandly met, that you could not feel otherwise than satisfied: and you have, probably, said within your own hearts, "here is peace at last—differences end—all are agreed—they leap to anticipate each other's views—*les beaux esprits se rencontrent*". Gentlemen, I must undeceive you. I have to announce with deep regret, that the correspondence has been most unsatisfactory throughout. We found a Bill, the proper title for which would have been "A Bill to authorize certain persons (to be nominated hereafter by some authority as yet undetermined) to levy on medical men sundry taxes, and to apply, or otherwise distribute, the proceeds of the said taxes in such manner as, to them, shall seem best, and for other purposes." I will not allow myself to entertain a doubt of the integrity and benevolence of those who framed that Bill; but such guileless men can hardly legislate for a hard-hearted and censorious world. I really doubt whether they were themselves aware of the oddity of their own scheme, until we drew their attention to this, its characteristic feature, for they gave it up at once. And here terminated the success of our negotiation. Let me ask you to give your earnest attention to the report which will presently be read, and more especially to the following subjects:—A registration, right in its general principle, but vexatious, harassing, and inefficient, is to be maintained.—A scheme of education wholly unadapted to ordinary practice: a scheme which we feel certain will, at an early day, call unqualified persons into open practice, the penalties of this Bill notwithstanding: a scheme which will not so much as inquire whether any instruction can be given, save in colleges, which are to have a monopoly of teaching that which we assert they are not qualified to teach—this is to be maintained. A board whose very inquiry will oppress, and, perchance, ruin the practitioner, whose merited success renders him an object of jealousy; but which will be wholly unable to cope with the supple licentiate who adopts the fashionable delusion of the day: a board which may suppress a failing, but which will itself quail before a thriving quackery—this is to be maintained. As regards the composition of the council itself: the circumstances of medical men in the country differ so widely amongst themselves, and more particularly from those practising in London, that we thought a certain proportion of the council ought to be derived from districts remote from each other and from the metropolis. You will only render me common justice in supposing, that I for one never contemplated that silliest of fantasies, a Medical Parliament, which has, indeed, found vehement partisans, but which must have resulted in our confiding our affairs to those in whom no patient would confide; but I do concur with others in thinking that no bye-law should be passed, no course of instruction established, without consulting those eminent physicians and surgeons who are to be found here and there throughout the land, and whose daily, cordial, and most confidential intercourse with other practitioners—whose high position, and whose independence of those ordinary circumstances which make or mar our prosperity, would render them no less invaluable as advisers in the council than as advocates and expositors of the wishes and requirements of their less dis-

tinguished—perhaps, in some degree, of their less fortunate neighbours. In this matter some little concession has been made. Soft words, fond hopes; but no guarantee, no assurance—we understand such blandishments. Let me entreat you, for the sake of those who come after us, to attend to another and a stranger regulation of this Bill. The candidate, after a collegiate curriculum, determined on all points by the sole authority of the Medical Council, will be required to appear before a Board of Examiners appointed by that Council out of the College of Physicians and the College of Surgeons. By that Board he will be examined as to his fitness to practise medicine, surgery, and midwifery. From that Board he will obtain a license (for which he will pay) declaring him fully qualified to practise those several branches of medicine. But this license will not entitle him to practise without incurring all the penalties of the registration clauses, unless he be registered. Well, then, let him go to the registrar, produce his license, and tender his fee for registration. The registrar's duty is to decline that fee, and to inform him that the license acquired by his examination before the united Board of Physicians and Surgeons, under the authority of an irresponsible Medical Council, is worthless and invalid until he has undergone another examination, at which he may be declared incompetent, either at the College of Physicians or the College of Surgeons, the very bodies whose representatives in the Council's Board of Examiners have already pronounced him qualified to practise. I need not observe that this is an unworthy device to extort a second fee. It was admitted to our committee, when I was present, that this second examination is superfluous and indefensible except on the score of expediency: but that it was necessary to conciliate the College of Physicians and the College of Surgeons, as those time-honoured bodies were found to stand too high in public estimation to be set aside by any medical council that is to be. I think those learned and influential bodies are quite justified in thus resisting any invasion of their rights. They simply perform their duty in defending that which they were constituted to defend; but recollect, the individuals who are hereafter to enter our profession are to be the victims of this compromise. This vexatious and anomalous proposal is to be maintained. There are other and serious objections, but we are less personally concerned in them. Yet, in the face of our protest—and bear in mind, gentlemen, all the principles of that protest were unanimously affirmed at our general meeting, last summer, in this very room (when there were present sixty members, none of whom so much as knew that medical reform would be mentioned—men from all parts of Devon and Cornwall, and of whom seventeen were practising physicians)—in the face of that protest, Lord Palmerston has been assured that “the Bill had received an unparalleled amount of support”—“that it was warmly supported by a vast majority of medical practitioners throughout the kingdom”—a vast majority of those practitioners never having thought, or cared, one iota about the matter; and that, “in fact, no opposition had been made to its principles, though some exceptions might have been taken to its details”. A curious and instructive example how far a sanguine temperament may mislead a mind—kind, candid, and just, I will assume it to be—thus occupied by its own notions to the exclusion of all others. That there are anomalies in our profession, all must admit; though I suspect, as personal grievances, they rarely affect us. Still they ought to be corrected; but they will not be corrected by the present Bill, whilst they would have been by that of Sir James Graham. But his Bill, unhappily, comprised a gratuitous affront, which was resented by the mass of the profession with startling unanimity. Instead of erasing the offensive part (which was merely an excrescence attached to the Bill, and scarcely connected with it), crotchety men interposed with their stupid advice, and soon made it so ridiculous, that its author, like a high-spirited gentleman, withdrew it in disgust—never, we may fear, to be again revived. With the present authorities we have some cause to be dissatisfied. The College of Physicians refused, greatly to their discredit, to superintend the profession when invited to do so; and so it happened that the charge of directing medical education was assigned to a civic corporation in London. As regards the encouragement of medical science and literature, the College of Surgeons have amply redeemed every pledge by their museum, their library, and their lectures; but they have shown little sympathy towards the members of their college generally. Will the new Council show more? Will they not be powerful to annoy, and powerless to protect? Beware of change; remember King Log and King Stork.

Dr. SHAFER, having been called on to read the report, explained that the committee had been appointed at the annual

meeting of the Association at Exeter, in September, to consider a draft bill of Medical Reform, which had been published in the Journal of the Association. The committee had presented a report to the council; and on the 10th November an amended draft appeared in the Journal. On the 24th Nov. the report was also published there, accompanied by a remark from the editor, that the objections it contained had been met in the new draft. The committee were not of this opinion, and had, therefore, drawn up another report, which they now presented. Dr. S. then read the report. After stating that the most objectionable parts of the bill appeared to be still retained, and that, as the construction and management was now removed from the Association to Lord Palmerston, it was necessary that any objections should be submitted to his lordship, the report proceeded to enumerate the objections entertained, which were, in substance, as follow:—

“That the 3rd clause of the draft Bill is deemed objectionable, because, in the appointment of the Medical Council for England, no adequate representation of the provincial medical practitioners is ensured, since it does not direct the appointment of any provincial medical practitioners. It would obviously be useful to the general interests of the profession, that perhaps not less than one-third of the members of the Medical Council should be selected (as equally and fairly as may be) from amongst those medical practitioners who are resident in the various counties of the kingdom. This clause is also objectionable from its entirely passing by all consideration of, and representation by, the Company of Apothecaries.

“That the 12th clause is objectionable, from its not sufficiently securing the monies to be derived directly from the whole mass of the profession; these being, as the clause now stands, vested solely in the council instead of in trustees thereto specially appointed, and separate from the council and examining board.

“That the 14th clause is objectionable, inasmuch as, while (together with schedule A) it confers the name and title of a ‘licentiate in medicine’, and grants a ‘license to practice medicine’, with the express statement that the person so designated and so licensed is ‘duly qualified to practise medicine’; both the title and the license to practise are, by subsequent enactments of the Bill, practically set aside.

“That the 15th clause is objectionable, from its omitting to direct, previously to the commencing of the required collegiate education, some time or form of studentship, together with a matriculation examination, whereby the possession of a previous sufficient elementary medical and general knowledge may be ensured. This clause is also objectionable from its neither recognising nor giving any special privilege to the extensive means of education afforded by provincial hospitals, with the exception of those few to which ‘medical schools’ may be attached. The effect of this enactment and of these omissions cannot fail eventually greatly to retard the attainment of sound practical information, as well as to be prejudicial to the personal interests of the profession at large. Medical education will thus be virtually, if not actually, transferred to the universities, or medical schools, to the subversion of that excellent and extensive means of practical medical instruction afforded by pupilage in provincial hospitals and apprenticeship under private practitioners, which has so long existed, and which has mainly contributed to form the useful and intelligent class of medical men now practising throughout the country. Doubtless ‘universities’ and ‘medical schools’ are most admirably adapted to convey information in medical science; but they must not be deemed the only sources whence early medical information is to be obtained, and if relied on solely, or even mainly, will fail to produce a useful and practically instructed class of medical men, trained to those habits of business which, in the general private practice of this country, are no less indispensable to the success of the practitioner than to the safety and satisfaction of the sick he has in charge.

“That the 17th clause is objectionable from its peremptorily obliging those who have been examined and licensed by the council (under the 14th clause), to undergo, in order to registration, a further examination by the College of Physicians or by the College of Surgeons; especially as the Bill in no way provides that these bodies shall be satisfied with the ‘curriculum’ prescribed by the council as necessary to their own examination. Moreover, by forcibly obliging the ‘licentiate in medicine’ to attach himself to one or the other of these bodies, it subverts the usage of this country, which has established, both nominally and practically, three divisions of the medical faculty, viz., the general practitioner, the surgeon, and the physician. Again, this clause is objectionable from its omitting in

any way to allude to, or to define the position of those who may, subsequently to the passing of this Act, have medical degrees conferred on them by the London or other British universities, with the exception of those of Oxford and Cambridge. The degrees thus derived are treated by this proposed Bill, apparently as regards title, and certainly as regards qualification, as worthless; those holding them being actually disqualified from practice, unless they shall be registered under this Bill, which can only be after an examination by the council, and by the Colleges of Physicians or Surgeons. On reviewing the whole bearings of this clause, it cannot but be regarded as anomalous and unjust; and though its provisions may probably be a means of averting opposition to the Bill generally, on the part of the College of Physicians or Surgeons, by guaranteeing to these bodies their present, or an increased source of income, yet this will be done at the expense of the future candidates for practice.

"That the 18th clause is objectionable, from its obliging medical practitioners annually to apply for, and to pay for, the certificate."

The portions of the report relating to the various clauses were then read over separately, and, after a few remarks, unanimously agreed to.

Mr. JAMES moved as a rider to that part relating to the 17th clause, that "the meeting are of opinion that, in dealing with the preceding objection, the purposes intended now would be much facilitated if the College of Surgeons were relieved from the burden of maintaining the Hunterian Museum, which they should still continue to superintend and govern as they have hitherto so ably done; and a very moderate assistance from the legislature would provide for this."

Mr. EMPSON having seconded the motion, it was agreed to.

Dr. SHAPTER proposed a resolution, expressing the satisfaction of the meeting at the introduction of a measure for the due regulation of medical education, and requesting the chairman to forward the resolution and the objections entertained against the proposed Bill to Lord Palmerston.

The motion was adopted.

On the proposal of Mr. Empson, the following motion was also passed:—"That Dr. Pennell, Dr. Shapter, Mr. Barnes, Mr. James, Mr. De la Garde, Mr. Pridham, Mr. Empson, Mr. Howard, and Mr. Kempe, be appointed a committee to watch the progress of the Bill."

A vote of thanks to the Governors of the Hospital for the use of the room terminated the proceedings.

YORKSHIRE BRANCH.

THE Annual Meeting of the Yorkshire Branch of the Provincial Medical and Surgical Association will be held at the Museum of the Yorkshire Philosophical Society, on Thursday, May 12th, under the presidency of R. Hey, Esq. The members and visitors will dine together after the meeting.

WM. MATTERSON, JUN., *Secretary*.

York, April 25th, 1853.

MEDICAL BENEVOLENT FUND.

THE monthly meeting of the Committee was held on Tuesday, April 26th. Two new annuitants were elected at £15 a-year.

The following cases were presented:—

- I. A general practitioner in the north of England in great distress. Voted £5.
- II. The father of the family is insane, and his children, eleven in number, are reduced to very straitened circumstances. Voted £10, to be placed in the hands of a judicious friend, so that it may be applied as circumstances indicate.
- III. A literary medical man in the country, well known and highly esteemed, reduced to the greatest distress and privation, and having a large family. Voted £15.
- IV. A young man, an assistant, with a very high character, who is obliged to leave his situation, and make a voyage to a milder climate. Voted £10.
- V. An aged medical man of high character, in reduced circumstances, requiring aid to enable him to carry on the battle of life. Voted £5.
- VI. The widow of a highly respectable medical man in the country, with a very large family, five of whom are entirely dependent upon her, and her own health not being good. Voted £10.

Several other cases were discussed and dismissed, some from

a failure of the proper recommendations, others from the absence or deficient evidence of unexceptionable moral character.

Since July 1st, 1852, the sum of £539:15:0 has been received in subscriptions, and £354:16:0 in donations, inclusive of dividends; there has been paid for benevolent aid £519, and in expenses £51:12:5, together £570:12:5, leaving the sum of about £30 due to the Treasurer, which by the grants at the meeting was increased to about £85. It is hoped that the friends and subscribers to the Fund will do their best towards liquidating this debt.

EDITOR'S LETTER BOX.

PRESSURE OF THE ASSESSED AND INCOME TAXES ON MEDICAL MEN.

LETTER TO THE EDITOR.

SIR,—Will you permit me to place before the readers of the ASSOCIATION JOURNAL the case of my friend Mr. James Fagg, surgeon, etc., practising at Pitside, in the parish of Drainless, Cheshire, as I know it is one among hundreds which might be brought forward to prove how unequally the assessed and income taxes press on medical men, compared with those who draw their incomes from property? The following statement is in Mr. Fagg's own words. I am, etc., J. R.

Manchester, April 30th, 1853.

"I am thirty-eight last birthday, thirteen years married, have seven children, and have been a practitioner of medicine at Pitside seventeen years and a few months. As my duties lie over a wide circuit, I have to keep a man servant, a gig, and two horses, one of them partly for the saddle; and the sum on which I have paid income tax, on the average of the last three years, is £505:10. As neither my wife nor myself has private fortune, it was deemed prudent, as children came very fast, that I should assure my life, which I accordingly did, five years ago, for £2,000, the annual payment on which is £52. Besides my man, gig, and horses, on which I pay the assessed taxes as if I were a squire (notwithstanding they are essential to my business), I pay a heavy house tax for a large, straggling dwelling, the only convenient one I can obtain, though double the size I should think of occupying except on account of business. The tax-gatherer, you will observe, makes no difference between what is *necessary* for myself and family merely, and what is necessary, in addition, for business. Moreover, no one, seemingly, takes the trouble to consider that my income is not only not from property, but that it is not even a life-interest—that, while the rector of our parish has his £500, which he holds for life, my income depends on my health and strength: supposing accident or illness, it terminates at once. In speaking of my paying the tax on an income of £505:10, you must observe that I have had to take £52 from this sum for life assurance, and that the £1:10:4 income tax on the £52 is not deducted, but that I pay on the whole of the income.

"Some of these things have galled me a great deal. Before the abolition of the window tax, I was in the habit of paying for twenty-one windows, four of which lighted my consultation-room and surgery; yet these latter were for business purposes alone; whereas our neighbour the grocer, whose corner shop (a part of his house) has three windows, paid no window tax on these. And in like manner I have been reminded of the unequal pressure of the other assessed taxes, when I have seen a number of my patients, opulent farmers, sporting their riding-horses and dog-carts, on which, because they were kept for business, there was no tax. You will perceive, therefore, that the surgeon, whatever his income turns out to be, has to pay the tax upon it, as also too upon the means or implements whereby alone he can earn an income, to be thus taxed, viz., his groom, his vehicle, horses, and house; upon these he has to pay the assessed taxes precisely as if he were an independent gentleman, the squire of the parish himself. Surely this is unjust on the part of government. I am a loyal man, and always will be; but this unequal dealing is very trying to the feelings.

"I have been thus particular in stating the items of my taxation, on purpose to contrast therewith the taxes of a neighbour, Mr. Stockton. This gentleman, formerly a steward, but now retired, fell heir, on the death of an uncle, to £17,000 in three per cents.; and now, with his wife and five children, lives, my respected neighbour, in a tasteful cottage, surrounded by an ample, fruitful garden. I may just remark, that being of a

cautious temper, he allows the money to remain in the funds as his uncle invested it.

"Now what are Mr. Stockton's taxes do you think? For his cottage he does not pay half the house tax I do on my house; his income, from the funds, being £510, he pays only about three shillings more income tax than I; and, besides a dog which he keeps for his own and children's amusement, has nothing that pays a tax. Groom, vehicle, and horses, he does not require any more than I should do except for the purposes of my profession. In addition to this, he has his time at his own disposal, which he uses for the benefit of his family, and the saving of expenses. Thus, I notice the fine crops of early peas and potatoes (of which he is kind enough to send us a dish now and then) raised by his own labour, or rather by way of amusement; and I am persuaded that he grows vegetables of all kinds for the supply of his family, to say nothing of the pigs and poultry which he breeds and rears for profit and use. He has other advantages over me in this complete leisure which he enjoys: he is tutor to his sons, and teaches his daughters music; whilst I, as I sometimes say, am half ruined by school-bills. Then, the care he can take of his health is much to be envied; whilst I, drudge that I am, must toil on, ill or well. I will make this very plain to you. Some four years ago, as I was hastening to a labour, about three o'clock of a winter's morning, along one of our interminable lanes, blinded by the drifting rain, my horse (like myself, half asleep I suspect) slipped into a marl pit (so common on the road sides in this quarter) throwing me into the water. On reaching my patient, duty demanded I should attend to her rather than my own comfort; the consequence was a rheumatic fever, which confined me five weeks to bed, kept me as many more weeks an invalid, and has left, I fear, some affection about the heart. At any rate, I doubt whether, after this, an assurance office would readily accept my life, or indeed, accept of one in three of the lives of our village surgeons. Even now I am a martyr to chronic rheumatism in damp weather, and can hardly dress myself without help; and, added to this, is a touch of the asthma, owing to which I find my night journeys trying to flesh and blood. Very different is it with Mr. Stockton. A couple of years ago, having caught cold in a shower, as he was teaching his daughter to fly a kite, he had rheumatism of the left knee, and since then slight stiffness in the joint; but the care he takes of his health (and can afford to take) is not to be exceeded, and the knee is made a plea for frequent visits to the Buxton baths, from whence he returns, he says, improved—quite a new man.

"Well! I cannot but hope that the Chancellor of the Exchequer will even yet consider the case of us surgeons, and lessen our burdens, or, at all events, treat us equitably. I have heard that financiers assert that an income, say of £500, from one source is just as good as £500 from any other source.—£500 from a profession such as mine, depending solely on the continuance of my health, just as good as my neighbour Stockton's from funded property, which is an income *for him and his family after him*, independent of all contingencies. Now, there is some truth, no doubt, in the assertion: £500 income once in the purse of the owner is as good to the pick-pocket, be it obtained from a profession or from property: the money he finds as good in the one case as it would be in the other; and the Chancellor of the Exchequer appears to be of the same opinion, for he deals alike with the two kinds of income. But the owner of the income *knows better than this*; he is of a different opinion. When I have got my £500 I know it is *all* that I possess, and that I must pay out of it my heavy assessed taxes and for my life assurance, and also put apart a tenth as a provision against unforeseen emergencies if I and mine are to keep clear of the parish. When Mr. Stockton, however, has got his £500 dividends, he knows that this is not *all* that he has, that it is only a thirty-fifth part of his property—in a word, that he has £17,000 in addition. Surely, a child could see through so flimsy a fallacy as this.

"With my wife and seven children, and another in prospect, and no provision but the before mentioned life assurance (if this indeed should not have to be dropped in the long-run from ill-health and consequent inability to pay the premium), I am sometimes almost tempted to emigrate. For, in her fretful moments, my wife says that she anticipates she will yet be obliged, in the end, to keep a boarding-house like the widow of my late friend Mr. B., surgeon; or, like her cousin in Salford, the widow of another surgeon, to hire herself out as a monthly nurse. But these, I tell her, are only 'fears of the brave' unworthy of her fine courage. In the meantime I wait to see what the Chancellor is willing to do for the profession. I am no member of your 'Manchester school' as it is called, but a

loyal subject, willing to pay all just and equal taxes for the support of the Government; and it is under this feeling that I have written what I now have. I fear, dear sir, you will think my case very prolix, not to say tiresome; if so, I cannot help it, it has been drawn up in the best manner I could. In mitigation of any censure you may be inclined to pass on me for this, I will repeat to you the homely negro adage I once heard from a friend many years in the West Indies. The negro, apt to be prosey, will say to any one who attempts to cut short his story, 'Massa, if you won't take time to kill a fly you can't see his guts'. So with this for your edification, I am, etc.,
"J. FAGG.

"P.S. I have said that I pay my assessed taxes out of the income returned, but I quite *understate* my case; because I have, in addition, to pay out of it, the wages of my groom, and the keep of my horses: I am not permitted to deduct these expenses. If I would make oath that I never use horses and gig excepting in professional visits, then the deduction would be allowed. But no surgeon (no country surgeon at any rate) whose life is spent, almost literally, on horseback or in his conveyance, can swear this: he cannot, in the nature of things, do so without perjury. For it will inevitably happen that, in his rounds, he calls at the house of a friend; that his wife has to be taken to and brought home from an evening party in the gig, or that an ailing child, perhaps, is sent for an airing in it, as was the case occasionally of late with one of my children recovering from whooping cough. To saddle the surgeon with income tax on the before mentioned expenditure for groom, gig, and horses, because of such trifling incidental services to his family, is to oppress the *weak*, whilst the *strong* are altogether passed over. Thus Mr. T., a very opulent silk-manufacturer, not far from this, dines daily with his sons and his partners in the counting-house (*quasi* a dwelling-house) at the mill, and yet he has not, for this, been charged with the house tax. And his porters carry his portmanteau to and from the railway station and do many like services for him and his sons, but who ever heard of the *tax on servants* being charged on these? Or, of their wages not being allowed to be deducted from the sum returned by Mr. T. as his income? J. F."

METROPOLITAN COUNTIES BRANCH.

LETTER FROM DR. T. O. WARD, TO THE EDITOR.

SIR,—Having received a notice from Dr. Semple that he intends to bring forward the subject of Medical Reform at the ensuing general meeting of this Branch, on the 10th of May; and also one from yourself, respecting the Vaccination Bill, it appears to me to be desirable that the utmost publicity should be given in the pages of the Journal to these notices, in order that every member of the Branch who is interested in them (and who is not?) may come to the meeting fully prepared for their discussion.

I am anxious to state that no circulars are to be sent to members, the advertisement which appeared in the Journal of April 8th and 15th, being deemed by the Council sufficient notice of the meeting.

I am, etc.

T. OGIER WARD, *Hon. Sec.*

Kensington, May 3rd, 1853.

EXTRA-URBEM LICENTIATES OF THE COLLEGE OF PHYSICIANS, AND THE PROPOSED CHARTER.

LETTER FROM HENRY JOHNSON, M.D., TO THE EDITOR.

SIR,—The readers of our ASSOCIATION JOURNAL, who are also extra-urbem licentiates of the College of Physicians, will have seen, by the draft of the new charter printed in your pages, how it is proposed to deal with that large and respectable body of British physicians. After being examined, and approved of, and declared fit to practise by the College, we are yet to come with certificate in hand, and are to be treated in all respects the same as those who have been practising all their lives in contempt of the charter, and as if we had never been in any way connected with the College.

I hope you will permit me through your pages to invite all members of the *Provincial Medical and Surgical Association*, who are also extra-urbem licentiates, and who have not already joined the ranks of the "associated extra-urbem licentiates", to lose no time in doing so, by sending in their names to the Secretary, Dr. T. Laycock, York.

I am, etc.,

HENRY JOHNSON, M.D.
One of the Committee.

Shrewsbury, April 29th, 1853.

MR. SYME'S OPERATION FOR STRICTURE.

LETTER FROM JAMES MILLER, ESQ., F.R.S.E., TO THE EDITOR.

SIR,—In your report of the discussion at the Royal Medical and Chirurgical Society, on the 26th inst., in the last number of the *ASSOCIATION JOURNAL*, the following passage occurs:—

Mr. Syme stated: "As to the case operated upon by himself in Edinburgh, and published by Professor Miller as an escape from extreme danger, he believed that the nervous symptoms described in his paper had imposed upon Mr. Miller; who, so far as he knew, had had no further experience of the practice than this single instance which he had witnessed as the family attendant. He did not believe that there had been the slightest ground for serious apprehensions in this case; and as the patient, after being for a year under this treatment by Mr. Liston without relief, had been restored to perfect health by the operation, he thought that, instead of being quoted as an objection to its practice, it should rather be regarded as a very favourable example of success."

In reference to this passage, permit me to observe:—

1. I am well satisfied that I was not "imposed upon" by "the nervous symptoms". They ("a curious train, consisting of rigors, bilious vomiting, suppression of urine, and delirium") certainly did occur; and that they did not cause unnecessary or unfounded alarm, was amply shown by their having been followed by perineal abscess which required incision, by pelvic abscess which was opened and discharged very copiously from the rectum, and by a painful as well as protracted and critical recovery.

2. I was not a mere "witness" "as the family attendant". The patient had been under the late Mr. Liston, and afterwards under my care. Extreme irritability of the parts prevented all systematic attempts at cure. At my request, he came to Edinburgh, with a view to consider the propriety of his submitting to the treatment by incision, then coming into use. On his arrival, Mr. Syme was, at my suggestion, called into consultation along with me; and, the operation having been determined on, it fell to be performed by Mr. Syme, as the senior surgeon, and the author of the mode of treatment. The patient was attended by me throughout his entire illness.

3. My personal experience of this operation is limited, simply because I have not found occasion, in all the cases of stricture recently under my care, to adopt any other treatment than that by the bougie. In certain extreme cases, I should not hesitate to resort to the use of the knife; but such cases have not occurred to me.

4. I am sorry to say that the case in question cannot be "regarded as a very favourable example of success". The urethra has now contracted to a considerably smaller calibre than that which was gained by the operation; the bougie is not passed without difficulty and suffering; and it will require much care to prevent decided relapse of the disease.

I am, etc.

JAS. MILLER.

Edinburgh, May 3rd, 1853.

P.S. I should not have found it necessary to intrude thus upon your columns, had the President's caution been duly observed. "He had not judged it proper to allow the usual practice to be departed from, by giving names publicly in the Society. Surgeons referred to by name in that way, in their absence, might with justice complain. It would be unusual and improper."—J. M.

NEWS AND TOPICS OF THE DAY.

MEDICAL ATTENDANCE AND CHARGES FOR MEDICINE.—CIRCULAR OF THE MANCHESTER MEDICO-ETHICAL ASSOCIATION.

THE Sub-Committee of the Medico-Ethical Association, appointed to ascertain the opinion of the profession in Manchester, on the expediency of discontinuing to make specific charge for medicine, have much pleasure in presenting the following analysis of the replies received to their former circular:

FAVOURABLE

UNFAVOURABLE.

72

4

The result of the inquiry gives every encouragement to pursue the matter further, in the confident hope of a considerable reform being effected in the present mode of charging for professional services.

The precise terms of the proposed change have, in a few instances, not been fully understood. The Committee, therefore, beg to repeat, that the object in contemplation is to establish the practice of charging for professional attendance only, the practitioner supplying medicine or not, as may be expedient. Among the large majority who are favourable to the plan, some have expressed an opinion that it would be difficult to carry out with the labouring class. Others have suggested a difficulty in the case where the practitioner having ceased to attend, a repetition of medicine is requested, which would involve a positive loss, particularly if the medicine were unusually expensive.

The Committee acknowledge the difficulty of accomplishing so great a change, without incurring numerous objections on the part of those who may still be prejudiced in favour of the questionable system of remunerating their medical attendant according to the quantity of medicine supplied.

A well directed effort, however, cannot fail of success with the intelligent part of the community, and here is the key to the whole question. Experience teaches that there exists a strong desire to escape from the abuse of medicine being made the means of a pecuniary gain. To this fact may be, in some degree, attributed the success of those practitioners who only prescribe, as well as the mysterious popularity enjoyed by those who eschew the use of medicine altogether.

The Committee desire it may be understood that they do not propose to endanger the plan by injudiciously attempting to carry it out in every instance; and they would repeat that the recommendation is limited by the term, "as far as practicable".

The Committee confidently appeal to the experience of those practitioners who, having tried the system with all classes, declare that the difficulties for the most part are imaginary, and that they vanish at once under the light of explanation.

After the most careful consideration of the whole question, the Committee beg to submit the following proposition, which they consider is well calculated to place the system of medical charges in a position more consonant with the claims of a scientific profession.

"That medical bills be made out as heretofore, merely giving the total amount, and specifying or not, as may be expedient, the charge made for each visit."

The practice of lumping together a long attendance in one amount affords no clue to the principle on which the particular items are calculated; and which, not unfrequently, is regarded as a questionable form of rendering an account.

The proposal to state the amount of the fee, comprehends the twofold advantage of declaring the terms of attendance, and satisfying the patient that he is not taxed with an unnecessary quantity of medicine. On the other hand, if the terms of attendance be not specified on the face of the bill, the Committee are of opinion that it will be incumbent on the part of the practitioner to embrace every opportunity of explaining the principles on which his medical charges are made. In either case the result would be the same, the more intelligent members of the community readily complying with the change, and being impressed with the integrity of the principle, will be found influencing and converting others to appreciate a plan that ultimately must obtain the approbation of all classes.

RICHARD ALLEN, *Chairman*.

NEW SERIES.

ANOMALOUS POSITION OF THE MEDICAL STAFF OF THE NORFOLK AND NORWICH HOSPITAL.

WE have on various occasions, in the course of our remarks upon hospital abuses, referred to the obsequious urgency and undignified diplomacy with which honorary hospital appointments are constantly being canvassed for in many metropolitan and provincial hospitals—learned and highly educated medical men being compelled either to renounce their chance of obtaining such posts, or to beg them cap in hand from a heterogeneous constituency of hundreds of “governors”, the overwhelming majority of whom are unable to form any estimate of the comparative qualifications of the candidates. The disastrous effects upon the medical profession of these hospital elections are becoming more and more apparent every day. Strategy is required to secure the votes of Lord Flummery (who pays his medical bill with patronage only, and who sends his sick servants to the hospital), of Dr. Rubric the rector, the Rev. Edward Whine the dissenting minister, Sneeze the perfumer, Sneak the tailor, Squills the druggist, and other electors of all sorts and conditions. The practice of this strategy must to a greater or less extent destroy the candidate’s feeling of self-respect, and lower at the same time his professional status in public estimation. Unfortunately, it is not only the hospital candidates themselves who suffer from this reckless pursuit of unpaid labour: the whole profession is depreciated in public estimation by the scenes enacted; and in extreme cases, such as that unfolded in the report of the Norwich Hospital meeting (to be found at p. 426), it is snubbed and sneered at, to the great extent possible within the conventional boundaries of gentlemanly language.

The Rev. J. Holmes said:—

“This was the relative position of the Board of Management, and their Medical Staff: the board as the controlling power, and the medical officers as a highly respectable body of men, but nevertheless persons who must, like other men, be controlled and supervised. He was confident that, if ever the medical staff should succeed in obtaining a dominant position in that board, the institution would certainly be ruined.”

Mr. Utten Browne was still bolder in giving utterance to his sentiments. He seemed to think that medical men, when under an accusation before the Board of the Norwich Hospital, had no claim to those ordinary rights of British subjects, which are shared alike in courts of law, by the peer and the peasant. A secret tribunal, on the model of the Spanish Inquisition, is his *beau idéal*. When the accused is a medical man, he would prevent sifting of evidence, or any pleading on his behalf. Here are the words of this man, as reported in the *Norwich Mercury*, and echoed in a leading article of that newspaper:—

“Let them only conceive the state of things which would arise if this proposition were carried. Suppose a question came before the board affecting in any way the conduct of a member of the medical staff. The medical members of

the board could muster in force; and though he was very far indeed from imputing to any one of those gentlemen a desire to take any particular course in order to shield any of their number, yet they knew that the *esprit de corps* was particularly strong among these gentlemen . . . and they would raise a discussion upon the point; and, though it was perfectly true that they would not have the right of voting, yet they would have the right of speaking . . . and it was very likely that they would be successful in inducing the board either to pass over the complaint altogether, or to say, without assigning any reason, that they were satisfied with the conduct of the officer who had been implicated.”

Such are Mr. Utten Browne’s ideas of the proper constitution and course of proceedings of a tribunal, for deciding “a question in any way affecting the conduct of a member of the medical staff”. It is not exactly “Jedburgh justice”;* for at Jedburgh they did try a man, only they unfortunately deferred the trial till after he was hanged. Mr. Utten Browne’s plan has no exact parallel, so far as we know, except in the rules of the “Holy Office”. The inquisition admitted that it was difficult, from its method of proceeding, to prevent many innocent persons from perishing with the guilty; but the *Directorium Inquisitorium* of the Dominican Nicholas Eymeric of Gerona supplies, in the following passage, abundant consolation for all mistakes so committed. “Let no person”, it says, “venture to affirm that he is unjustly condemned; or venture to complain of the censures of the church. But if he be unjustly condemned, let him console himself with the reflection that he has suffered for righteousness’ sake.” Even this comfort will not be left to the Norwich Hospital medical staff, should the present law remain unrepealed. If thwarted, censured, or unjustly condemned by their “supervisors”, they will only be able to console themselves with the reflection that they are suffering the penalties of a system, which they never ought to have allowed to come into existence.

Had Dr. Copeman not withdrawn his motion in favour of Mr. Johnson’s amendment, a much greater degree of importance would attach to the adjourned discussion than can now be the case. When a man takes the field as the champion of a principle, it is more useful to the cause of truth for him to be beaten, than for him to avoid defeat by making a compromise. Dr. Copeman had a good cause; and he supported it in a straightforward and convincing address. He might possibly, upon a division, have been in a minority of votes; but so just and necessary a reform as that which he advocated can never be long prevented, if perseveringly demanded in as moderate and as conciliatory a tone as that which was adopted in the written application and in the speeches of the hospital staff. The majority of the governors, if rightly dealt with, must ultimately discover that the medical staff of an hospital, if it perform its duty to the institution, is its great financial pillar, as well as its ministering arm. They must also sooner or later agree with Dr. Ranking in thinking that the medical officers “should not be placed in the same position as the porter or

* Scottish, “Jethart justice”.

nurse of the establishment, to be sent for by the board when wanted"; and they will not then unite with the *Norwich Mercury* in insulting medical gentlemen by comparing their position with that of menials.

Lest any one should suppose that we are unfairly censuring the newspaper organ of the anti-medical governors, we reprint a passage from the leader to which we have already referred:—

"The *real cause* of the proposition, however, jumped out in the very few words which fell from Dr. Ranking—that the medical men did not like to be placed upon a level with the nurses or the porter, to be sent for when wanted. That this is 'the rub', was evident, and we confess we heard it with regret, for it argues a false feeling, which is not generally the companion of strong intellects and high minds."

Alas! alas! to how low an ebb in social estimation has the hospital system of England brought our profession! It has tarnished the native lustre of medical philanthropy, and changed the voice of public thanksgiving into that of scornful ingratitude:—and who can

"Cover the monstrous bulk of this ingratitude
With any size of words?"

THE CRIMINAL PRODUCTION OF ABORTION BY PERSONS CALLING THEMSELVES SUR- GEONS SHOWS THAT A MEDICAL REFORM ACT IS REQUIRED AS A MEASURE OF PUBLIC SAFETY.

A most disgraceful instance of the criminal production of abortion, in which the characters of a clergyman of pious repute and of two persons calling themselves surgeons are involved, has been several times within the last fortnight brought before the Hon. G. C. Norton, at the Lambeth Police-office, and will soon be tried before the Criminal Court. A Mr. James Thompson Currie, a practitioner in London, has (according to the evidence published in the newspapers) for some time past been acting as the accomplice of a man named Cunningham, *alias* Smith, who was in the habit of seeing pregnant females at Currie's surgery, for the purpose, as it is presumed, of causing them to abort by the employment of mechanical means. The case which led to the discovery of the criminality of Cunningham, and to the implication of Currie subsequently, took place at the house of a Mrs. Halcomb, at 4, Stockwell Road, Clapham Road. A young woman, named Eliza Mardon, took rooms under the guidance of her seducer, the Rev. Mr. Gordon, at Mrs. Halcomb's house, and received medical visits from Cunningham, who informed Mrs. Halcomb that the young lady was suffering from a polypus of the womb, which it would be necessary to remove. On one occasion when Cunningham was alone with the lady, her cries were so loud that Mrs. Halcomb made an excuse to enter the bedroom, where she saw sufficient to lead her to opine that a foetus and not a polypus was being evolved from the womb. Cunningham was seen by her to remove something from the bed, and to take it away with him.

After a time Mr. Darnton Greenwood, of Clapham, was called in. He formed a decided opinion that the patient had recently passed through the process of labour, and gave such information to the authorities as led to the arrest of the two above-named prisoners.

On examining the medical directories, we find no men-

tion of the name of the prisoner Cunningham; but Currie is described in the *British Medical Directory* as L.F.P. and S. Glas., 1839. We should be sincerely glad if time might show that neither of them belonged, by qualification, to the medical profession. Nothing can point out more strongly, than the occurrence of such cases, the duty we owe to ourselves and to society, of applying with renewed zeal for such a measure of medical reform as would draw a line between qualified and unqualified practitioners.

Criminal abortion is, we fear, a much more common crime than many of the good and the just amongst us may suppose; and we therefore deeply deplore that the medical colleges cannot rid the profession of miscreants, who are found out in the commission of this sinful and horrible practice. The conduct of Mr. Greenwood, in the present case, seems to us to have been careful, just, and well deserving the earnest approbation of the profession and of society; but no one can save the medical profession from sharing in the disgrace of such discoveries, till there is a legal register of qualified practitioners, and a medical council, with power to erase from it the names of delinquents. We would earnestly say to our colleagues, that an opportunity at present exists, such as never before existed, for obtaining a useful measure of medical reform; and that, with such scandals as that to which we have now called attention damaging our social reputation, it becomes a duty to meet each other in the spirit of the most liberal concession as regards our class interests, and to rally round Sir Charles Hastings and his colleagues in the Medical Reform Committee of the Provincial Medical and Surgical Association, in obtaining at least an instalment of reform during the present session of parliament. Nothing will tend more to the accomplishment of this object, than our pouring petitions in profusion upon the table of the House of Commons. By signing such a form of petition as that which we published last week, no one will compromise his individual opinions upon matters of detail; and those who have strong views upon any matters of special difficulty, can easily make them known through the medical journals, or through the medical committees which are now being formed throughout the kingdom. At the present crisis, we require on the one hand full and free discussion, and on the other a brotherly and patriotic spirit of mutual concession. The conciliatory spirit in which the discussion of the Reform question was conducted at the meeting of the Metropolitan Counties Branch on Tuesday, is an omen of good. A full report will be found in another part of this number.

ORIGINAL COMMUNICATIONS.

TRAUMATIC LESION OF THE EYE.

By H. HAYNES WALTON, Esq., F.R.C.S., Surgeon to the
Central London Ophthalmic Hospital, Assistant
Surgeon to St. Mary's Hospital, etc.

CASE. SUMMARY:—PENETRATION OF THE LEFT EYEBALL BY A PARTICLE OF IRON: PROLAPSE OF THE IRIS, AND CLOSURE OF THE PUPIL, WITH ALMOST CONSTANT PAIN IN THE ORGAN FOR SEVERAL WEEKS: SYMPATHETIC INTOLERANCE TO LIGHT, AND CONSIDERABLE DIMINUTION OF THE POWER OF VISION IN THE OTHER EYE: REMOVAL OF CORNEA AND GREATER PART OF IRIS FROM THE WOUNDED EYE: ESCAPE OF SEVERAL MINUTE PIECES OF OXIDISED IRON: CESSATION OF THE LONG-CONTINUED PAIN: COMPLETE RESTORATION OF THE FUNCTION OF THE RIGHT EYE. REMARKS.

A **HALE** powerful man, forty years of age, whilst pursuing his avocation of boiler-making, on the 20th of January, 1853, was wounded in the cornea of the left eye by a piece of the metal which he was chiseling. The iris prolapsed, and the pupil was destroyed. There was not any evidence that the splinter of iron had entered the eye; indeed, appearances were rather against such an occurrence. A few days subsequently, there was an accession of pain, which was ever present during waking hours. Mr. Ernest Elliott, the surgeon of the government establishment at Plymouth to which he belonged, resorted to such measures as were adapted to subdue it; but, finding them ineffectual, and discovering that the other eye evinced symptoms of sympathetic disease, he sent the man to London for my advice. I saw him on the 16th of March, admitted him into the Central London Ophthalmic Hospital, and made the following note of his case:—"The left eyeball is much inflamed, and apparently disorganised, inasmuch as it is enlarged; and the cornea, which has been divided, is opaque, and bulges. There is not any perception of light. There is pain, sufficiently intense to disturb sleep. The journey has rendered this symptom more severe. In the right eye, there is slight pain, with preternatural vascularity of the conjunctiva; considerable intolerance of light, so much that a sheet of white paper cannot be looked at without uneasiness. Vision is not sufficiently perfect to enable him to read the type called *English*. There is much general prostration. The tongue is foul. He has no appetite."

From some experience in parallel instances, I had not any doubt that the piece of iron, which had impinged on the eye, had passed to its interior, and was yet incarcerated; and, on the conviction of the correctness of such diagnosis, I excised the front of the eyeball to allow of its escape. The greater part of the iris was also excised—a result that was inevitable, at the same time desirable, from the close apposition of this membrane with the cornea, the result of the prolapse. A large amount of what appeared to be aqueous humour escaped. A little of the vitreous humour was lost. The crystalline lens was absent. The eyelids were closed, and retained shut by a strip of plaster; and the patient sent to bed.

On the morning of the second day after the operation, he removed from the corner of the eye with his finger two pieces of iron-rust, about the size of pins' heads. A day later, a third bit was cast out.

On the 23rd, my note runs:—"His relief is very decided. There is only occasional pain in the eye; and, from his description of it, it is rather darting than dull. It is probably due to the operation. The surface of the vitreous humour is covered over by a greyish-white pulp-like deposit. The conjunctiva is yet very vascular, and bathed with purulent secretion. The other eye is fast recovering itself, is no longer red, and can bear bright light much better. He can

actually read the *Times* newspaper." Soon after this, he left for home; and when I heard from him, on the 8th of April, he stated that all pain had ceased, and that the right eye was daily improving.

REMARKS. While certain affections of the eye are for the most part consigned to those who practise for ophthalmic affections on a large scale; and while some may without detriment have their treatment delayed for awhile, there are several which, from their emergency, require prompt attention, and, which all surgical practitioners should be prepared to undertake. Now, mechanical lesions constitute one class of those which call for general attention. It is a class of much importance, and susceptible of much practical comment; but I must restrict myself to that division of it under which my case falls (foreign bodies within the eyeball), and at the same time maintain a strict reference to the individual example before me.

The first practical lesson here taught is the impossibility of our being able to determine, from the mere appearance of a wound, or, in the first instance, from the sensations that succeed to it, whether a body has or has not passed into the eyeball. Prolapse of the iris does not afford any indication either way; and it frequently happens that, with the presence of a body, there is not immediately any pain. Perhaps, while the vitreous humour is the resting place, sensitiveness is not manifested; but then even one or the other of the chambers of the eye may not directly resent its lodgment there; yet, on the other hand, there may be pain, immediate, intense, and enduring even for weeks, as the effect of a wound alone. Therefore, in traumatic injury, when we cannot see any foreign substance, after attempting to replace the iris, should there be a probability of the attempt being successful, and adopting such measures as are likely to ward off inflammation, we must patiently abide the result. Even with strong suspicion or positive assurance of a body having entered, should it be out of sight (supposing vision not lost), it would be certain destruction to the eye, and therefore malpractice, to seek guideless for it; and it must be borne in mind, that its presence is not necessarily fatal, as some substances may dissolve, and any may become encysted. But should vision be assuredly destroyed, and the cornea or the sclerotica be extensively wounded, the sooner, by the excision of a part of the eyeball, an exit is afforded for its escape, the better. In any case, after inflammation has set in, attended with much pain, and the means to subdue them have failed, and the eye is evidently disorganised, we ought, I think, to act as if sure of there being a foreign body present; and excision should be practised, as a means of averting suffering, and securing the other eye from a sympathetic attack. Certainly it should be executed directly that sympathetic inflammation sets in. In my patient, the sympathetic attack was unusually early.

From these principles of practice not being generally recognised, many eyes are annually sacrificed. On the value of their observance rest the chief merits of this report. For the valuable facts on which they are founded, we are indebted to Mr. Barton (see report by Mr. Crompton, *London Medical Gazette*, vol. xxi); and the reiteration of them here cannot be superfluous. In seven cases, a fragment of copper cap was driven into the eye; and, from the symptoms, it was not possible to determine whether the cap had entered or not. The eyes not wounded became affected; loss of vision was threatened. Mr. Barton, suspecting the nature of the cases, excised the cornea, and applied poultices, in the hope that the fragments of copper would escape, and the cause of irritation, with its threatenings on the other eye, would be removed. In all of the number, the copper passed out, and was found either in the coagulum of the wound or in the poultice; and the effect on the other eye was magical.

Now, concerning the manner of operating, I do not consider it immaterial. I suspect that, to be certain of the result we seek, the iris, i. e., the greater part of it, should be removed, together with the cornea, or else it may be an obstacle to the body coming away. Where it is prolapsed

(and it has been so in all the cases with which I have been concerned), a large portion of it must necessarily be removed. The details of my operation may be thus expressed. After an assistant has retracted the eyelids, I transfix the cornea with a curved cataract needle, and with a cataract knife cut away the required portion.

69, Brook Street, Hanover Square, London, April 1863.

FAILURE OF VACCINE.

By J. A. HINGESTON, Esq.

THE frequent failure of vaccination is now so generally admitted, that statistical proofs are not requisite in order to establish its truth. People look upon it as an equal chance, whether those who have been vaccinated shall be able to resist an attack of the small-pox or not, should they be exposed to it; while some go so far as to surmise, hastily and rashly enough, that vaccination is all but useless. A few vote for a return to the old variolous inoculation; and a few, still more inconsiderate, boldly declare themselves in favour of the small-pox itself, as the only and the surest guarantee of their safety. There is, of course, a great deal of exaggeration and misrepresentation in expressions of this sort; and much more is affirmed against the non-protective agency of vaccine lymph, than, as is usual, a dispassionate inquiry into all the circumstances of the case will justify or imply. The broad and undisputed fact of the actual diminution of small-pox since vaccination has been introduced and practised, is alone sufficient to contradict these wild notions, and to refute the vulgar prejudices aloft upon the subject. For, even during an occasional outbreak, the disease is nothing now to what it used to be formerly, when the old inoculation, which is itself not free from risk, was the only obstacle opposed to its incessant and alarming encroachments. At that time, it was a real plague of terrible malignity, whereas it is now a comparatively mild and transient epidemic. This well-known fact is a satisfactory answer in favour of the protective influence of vaccination, which, if not universally, is at least extensively serviceable and effectual.

To medical men, the occasional failure of vaccine lymph presents itself in a very different light from that in which it is viewed by the public at large; and with vaccinators in particular it is a topic of the deepest interest, which they endeavour to explore to the best of their abilities, and in every possible direction. The various points of inquiry offered to their notice, may be reduced to the few following items.

I. A chief cause is the capital oversight on the part of the vaccinator himself, in transferring lymph from an imperfect pock. There is no doubt that this oversight or carelessness is a copious source of the quantity of bad lymph in circulation, as well as of the ultimate failure of vaccination as a protective agent. For it is a maxim in vaccinating, never to transfer lymph from a pock in the slightest degree abnormal, nor from a normal pock in a constitution evidently disordered or unsound; because, if it be so transferred, the inevitable result will be abnormal pocks and inefficient lymph. It is impossible to restore contaminated lymph to its primitive purity; no subsequent care in its propagation can ever recover its lost or defective virtue. Having once become devious or degenerate, it continues to descend both degenerate and devious, until its power becomes extinct, and it fails to propagate itself, even in a degenerate form. This glaring fact is so unquestionable, that it is necessary to bring it forward, and place it first and foremost among the causes of the failure of the vaccine lymph.

II. Another main cause of failure is, we must candidly own, carelessness in the act of vaccinating. Not only is the good quality of the lymph used not strictly inquired into at the outset, but, what is more unpardonable, the mode of operating is not exactly performed. There is a

right and a wrong way of vaccinating, just as there is a right and a wrong way of amputating, bleeding, or tying an artery. Every surgeon knows the value of performing an operation rightly, and the evil consequences to be apprehended from operating wrongly. It is the same with vaccination, which, in its vital results, takes rank among the capital operations of surgery, and requires, for its proper performance, an intelligence as clear and a hand as dexterous as ever fell to the lot of the best of surgeons. By neglecting, or by not being aware of, the precise way of operating, it happens that so many vaccinations turn out, either eventually or immediately, inefficient. The puncture is made too wide or too deep, or irregular; each of which faults materially affects the shape and character of the vesicle; or else, if it have been properly performed, and the lymph effectually inserted, it is not punctually watched from day to day throughout its progress. Success demands constant vigilance. In performing the operation, the cuticle alone must be raised, and the cutis beneath exposed, but not wounded, or wounded as little as possible. The cutting, or rather the scratching, of the cuticle, should be done lightly and delicately, with the least possible irregularity, and over the smallest extent of surface consistent with the application or insertion of the lymph. Its course must be watched and noted on the third, eighth, and fourteenth days in particular; and no case can be pronounced safe, unless every step in its progress have shown itself to be regular, critical, and complete.

It is very necessary to point out these causes of failure; first of all, because they are frequent, and seem, in a great measure, to have lost of late years something of their due weight and importance in the estimation of medical men.

From the medical pupil never having been hitherto distinctly educated on the subject of vaccination, he is naturally liable to fall into mistakes through inexperience, which can only be overlooked out of tenderness to his unavoidable ignorance, in consequence of his never having been taught, *ex officio*, how to proceed with scientific precision. But, upon public grounds, inexperience is inexcusable, and cannot be too severely censured and condemned.

III. Owing to a want of attention to the proper time for taking it, the lymph is transferred too soon or too late, and the obvious consequence is, that unripe or effete lymph is procured and propagated. Of course such lymph is weak, or altogether inefficient. It ought never to be taken away earlier than the eighth, and sometimes not before the ninth day. At too early a day, it is ichor rather than lymph. Again, it may be taken away too late; that is to say, after the ninth day, when it is becoming purulent, and the vesicle is turning into a pustule. The exact time is eight times twenty-four hours, dating from the hour of the day of vaccinating. The lymph will remain genuine till the ninth day is over, and sometimes even till the tenth; for occasionally the whole course of the pock is stage by stage a day after its time: thus, the inflamed point of the third day is delayed till the fourth, and the inflamed halo of the ninth does not reach its climax till the tenth, and so on. This delay in the progress of the symptoms is regarded as a favourable prognosis; and certainly, in cases disposed to reject the specific action of the virus, the inflammation and vesicle, besides their being abnormal, arise and disappear much too quickly. Lymph taken after the tenth day is universally reprobated; and none but such as are miserably ignorant or indifferent would ever think of transferring it at this late epoch.

IV. It is advisable never to transfer lymph that has become purulent. A prudent vaccinator never does. That that *pus per se* invalidates the lymph any more than blood does; for it may appear on the ninth day mixed with the genuine lymph: nor would its accidental presence weaken or destroy its efficiency; but it indicates more inflammation than is necessary for the production of the vesicle, and it moreover signifies the co-existence of an inflammation different in kind from that which produces the genuine lymph. After the tenth day, the lymph is

mixed up with the contents of the vesicle, which is thenceforth rapidly declining, and ceasing to be prolific. A blow or injury of the vesicle will hurry on the appearance of the tenth day, and consequently render the lymph unfit for transfer. Sometimes the first stages of the pock are suppressed, and then it breaks forth all of a sudden into its normal appearance of the eighth day; but such a pock is invalid.

v. Many parents, especially in the upper classes of society, object to lymph being taken away from their child's arm, lest, as they fancy, it should weaken its ultimate effect. A prejudice of this kind would extinguish vaccination altogether. Nevertheless, there are not wanting acute observers who consider that, if all the vesicles be exhausted of their lymph, the prognosis is thereby rendered unfavourable, and, moreover, that such exhaustion causes local irritation and disturbance. Indeed, it is affirmed that convulsions and death have ensued from such a proceeding. Be this as it may, it is certain that every one concurs in the propriety of leaving one vesicle intact, for the express purpose of judging of the normal progress of the pock from first to last; and no one would, we should suppose, be so imprudent as to irritate the exposed surface with the lancet or an ivory point, merely for the sake of draining it of every drop of its lymph. Yet it may be well to bear in mind, that one of the causes of the failure of vaccination as a protective agent, is imputed to thus draining the exposed vesicle—an error which, if it be one, it is easy enough to avoid.

vi. Lymph should never be taken from any but a primary pock. The pock resulting from a revaccination is not to be relied on. If there is any reason to doubt the vesicle being a primary one, it ought to be rejected.

vii. The actual or suspected presence of scrofula, syphilis, porrigo, etc., is quite sufficient to condemn the subject of it as a legitimate source of fresh lymph. A vesicle on such a subject, however perfect, should be allowed to die out by itself. Indeed, any eruption of the skin is a barrier against vaccination, except under the imminent risk of catching the small-pox; but as to transferring matter from such a constitution, it is out of the question.

viii. The sudden accession of constitutional disturbance during the pock, or the increase and extension of the inflammation around it, should render the validity of the operation more than doubtful. A second vaccination should be attempted within six months from the first, and the sensitive feelings of mothers opposed to such a proceeding should be steadily overruled. Many a vaccinator, not satisfied with a first pock, would wish to repeat it until he felt confident in the normal character of the last produced. But he is seldom permitted to adopt this wise precaution; and this may be numbered among the causes of failure in vaccinating. The forms of society tie our hands, and force us to comply with its own conventions.

ix. The number of vesicles is said to modify the result of vaccination. Some maintain that one alone is sufficient, while others declare that several are requisite, to insure efficiency. There is no proof to support either the one or the other of these two assertions. Pathologically speaking, it would seem, *a priori*, that the existence of a single good pock manifests the saturation of the system with the virus as entirely as any multitude of them would do. But as a matter of fact, there is nothing to help us in arriving at a decisive conclusion respecting it.

x. The most popular notion concerning the failure of vaccine, is that derived from its supposed contamination by passing through so many successive generations of mankind. This is the most popular belief, and the one which appeals most readily to the greater number of minds. Nevertheless, of all the different reasons alleged for accounting for the acknowledged fact of deteriorated lymph, this would seem to be the most untenable. It is an hypothesis built up in the face of facts that directly contravene it. For genuine lymph, dating from the time of its first introduction, continues to produce a genuine vesicle from a genuine vaccination performed on a subject in a genuine

state of health, as exactly now as it at first produced it under the hands of Jenner himself. Lymph, fresh from the cow, is certainly more energetic than such as has been long ago in use; but the pock that it produces is identical, and its immediate and ultimate effects upon the constitution are the same. This hypothesis, likewise, fails in explaining the failures that happened even in persons vaccinated by Jenner. We must look for the cause of deteriorated lymph in other sources than this.

xi. Dry lymph is said to be another cause of failure, and the use of liquid lymph is enjoined. No doubt, liquid lymph, and vaccination from arm to arm, is always preferable, but it cannot always be brought about. Besides, there is no solid ground for supposing that the virus, when dry, upon points, between glasses, or in a crust, is not equally as active as when it is still moist and quite new. Every vaccinator is aware of this. Lymph may be taken to India and brought back again, and still prove energetic and effective.

After all that has been said, the most apparent cause of failure is that of vaccinating with lymph taken from an irregularly formed vesicle, or from an unsound constitution, or at a wrong date of the pock. Independent of all other causes, this inadvertence or carelessness cannot be overlooked.

The signs of an obnoxious or doubtful vesicle ought to be closely studied. They are both constitutional and local. The health may be cachectic, the child suffering from debility, or some congenital infirmity or malformation. In these instances the pock is worthless. Regular vesicles may coexist with an irregular one, which alone is sufficient to invalidate the integrity of all the rest—unless its irregularity can be accounted for by something purely accidental.

The following eight points should be impressed on the memory:—1. Irregularity of form throughout all the stages of the pock. 2. The vesicle not being round. 3. The colour of the inflammation not being fresh and rosy, and that of the vesicle not of a pearly whiteness. 4. Its fluid contents being straw-coloured, instead of colourless and transparent; or else being purulent on the eighth day instead of the tenth. 5. The areola, or surrounding inflammation, not being defined and circular, but, on the contrary, irregular, confused, and, as it were, blended with the vesicle, whereas it ought to be distinct from it. 6. The crust forming prematurely, looking pale or yellowish-brown, and being friable and gritty, instead of dark, round, and compact. 7. The vesicle forming on the fifth day, and rising up of a conical shape, or festering like a small pustule. 8. The areola becoming efflorescent, or scurfy, or shooting out into a figure like the margins of a map. All such cases should be rejected without hesitation, and a second vaccination should be earnestly advised. It is by vaccinating from vesicles, more or less imperfect according to this description, that so many failures are recorded.

Laxity of practice in this respect is owing to vaccination not being hitherto included within the pale of legalized medicine. Any one may vaccinate as he pleases. There is no recognized authority to guide or check him in his pursuit, and no one is responsible for the lymph he uses, nor for what he thinks proper to circulate. Vaccination has slipped out of the guardianship of Jenner's learned successors, and has been allowed to pass into the custody of a so-called inferior grade of the medical profession.

Few know the criterion of a perfect vaccine vesicle—"The pearl in the rose,"—as Jenner admirably defined it. The practised eye alone can descry it. Too often it is looked upon but in a loose way: a pock, more or less perfect, runs through its course in fourteen days; and this is reckoned a sufficient evidence of its authenticity. Far from it: much more accuracy than this is called for, before a certificate of its completeness can be justly drawn up and signed. It must have been minutely correct in each step of its progress, not only apparently correct upon the whole; it requires a studious attention, the most refined in the practice of medicine; and the superficial haste with which vaccination is sometimes conducted and dismissed, is enough to rouse

the shade of its great discoverer from his resting place among the dead.

The manner, likewise, in which the lymph is preserved on points or glasses, is not more praiseworthy. It is carried about in the waistcoat pocket, or laid aside in a warm room, or left in a damp corner, where it spoils or turns putrid. And who can expect that, after being treated in this way, the lymph should take effect, or that, if effective at first, it should prove eventually genuine? It is folly to suppose it.

My much honoured father, who was a careful vaccinator of the old school, "remote from consequence, and unknown to fame", vaccinated from crusts that had been allowed to form and dry up unmolested. He was very particular in his selection of these crusts; for, after rejecting a great many, he would retain but a few for his private practice. He kept them enclosed in a covered box, in a dry place, in the dark, for he had a notion that light and air were prejudicial to them. They were round, blackish crusts, indented in the centre, and greyish on the inside. When he intended to vaccinate from them, he mixed up a drop of distilled water, or water that had been boiled, with the point of his lancet, in the hollow of the inside of the crust until he had stirred it up into a thickish fluid. With the lancet, thus armed, he vaccinated confidently. He used to say that, though it was matter apparently taken on the fourteenth day instead of the eighth, yet the crust comprised the virtue of the entire pock, and that the centre of the crust contained the lymph of the eighth day, undisturbed, and in its utmost vigour. This was the reason why he preferred the crust to matter drawn from the vesicle. Jenner preferred catching the lymph as it oozed out of a vesicle perfectly ripe; and Dr. Walker used to remove the epidermis altogether, and take the matter upon glasses from the exposed base of the ulcer, without any ulterior damage that I can remember; for Dr. W. was an excellent vaccinator, and most punctilious in all his observances.

There are certain signs of a genuine vaccination which are pathognomic. The microscope reveals a small vesicle within forty-eight hours after the insertion of the lymph, while the unaided eye can as yet discern nothing but a tiny scar with a faint blush. By passing the finger gently over it, a small elevated point is perceptible. On the fourth day, the redness, which is more decided, ought to have a dark central point in it, over which forms a small vesicle of a dull white colour. As the surrounding inflammation extends, it should be circular, or only slightly oval, in correspondence with the long axis of the puncture. Its margin must be well defined, and the inflammation itself full, red, and shining. The vesicle ought to be quite round, with rounded edges, and a central depression, as if the finger had pressed it down; but it becomes more elevated on the eighth or ninth day—the centre rises up and the circumference sinks.

The constitutional symptoms ought to be trifling. Adults complain of headache and lassitude, and the pulse becomes quick. A gland may become tender in the axilla. In adults, too, the vesicles are thinner and more easily torn, and the lymph is more yellowish, and the areola broader, than in children. The tendency to lichen, however, is not so great.

The areola should develop into a halo of erythematous character. It should itch, and the adjacent skin should sympathize beyond its margin. Its diameter is one or two inches. A number of little vesicles, filled with an amber coloured serum, sometimes arise upon it. The areola is the discriminative sign of a laudable vaccination. On the eleventh day it declines, its colour fades, and, as it passes away, it leaves behind it one or two concentric rings of a blueish light grey colour. It is almost gone on the thirteenth day; the vesicle hardens, and a circular dark brown crust remains. Beneath this crust, the fluid dries up, beginning at its centre. At the end of twenty-one days, the crust falls off, leaving the skin beneath clean and entire, but at first reddish, the site of the pock being marked with a scar, which eventually becomes flat, shining, and colourless. Its shape is zig-zag, and its area exhibits a number of depressed points corresponding with the cells of which the vesicle had

been composed. For the vesicle, resulting from each puncture, is made up of little cells intercommunicating with each other, and secreting a perfectly transparent colourless lymph, which on the seventh, eighth, and ninth days is at its full maturity, and ripe for transfer. After this crisis, the lymph becomes thicker, less transparent, at last purulent, and unfit for transfer.

These signs are as important as those which indicate a dislocated joint, or a strangulated hernia; and they are as indispensable to the correct diagnosis of its nature as they are to the scientific application of the rules for treating it.

There are, however, some deviations incidental to an efficient vaccination, which do not invalidate its protective quality. The local inflammation may transgress its limits, extending upwards and downwards, from the wrist to the shoulder and thorax. It may become erysipelatous, and an open ulcer may form in the place of the usually fair and placid vesicle; a papular eruption may break out and spread over the extremities and trunk. Such things may happen without damage to the specific action of the virus; and, it has been affirmed, that an eruption of this sort is a favourable sign, by showing the system to be thoroughly imbued with the lymph. It may be so, and the vaccination may be complete; but it weakens our confidence in its results, and certainly the lymph is not the most approved of, if transferred.

In the foregoing short remarks, I have confined myself exclusively to the consideration of the means proper for the transfer of genuine lymph. I have likewise attempted to point out a few of the characters of genuine lymph itself, without which, success is impracticable. There are many other circumstances connected with vaccination, which may be reserved for a future occasion. The main object in view is that of directing attention to an accurate knowledge of the true vesicle (so little appreciated), without which all hopes of keeping up a constant supply of good lymph are delusive and pernicious. The stock from which we derive it may be the most authentic in the world; but only let it fall into the hands of a careless practitioner, and it will be sure to disappoint our reasonable expectations in the second or third removes, and will not fail sooner or later to cease altogether in taking effect, or else go doggedly on in engendering any thing but an approved and perfect pock. Hence it arises, that so many false or imperfect pocks are observed, that the protective power of the lymph is weakened or lost, and that vaccination itself has fallen into so much disrepute and neglect.

Brighton, May 1853.]

AUSCULTATION, WITH REFERENCE TO THE SIMPLIFICATION OF TERMS.

By A. WHYTE BARCLAY, M.D., Medical Registrar to St. George's Hospital.

I TURNED with anticipated pleasure to a paper by Dr. Theophilus Thompson in the *Journal* issued on the 29th of April, the object of which seemed to be to simplify and correct the arrangement and nomenclature of the stethoscopic signs of disease in the lungs. With most of the observations there made, I most fully agree; and I am glad to find one of the physicians of the Hospital for Consumption deprecating that over-refinement, and those excessively minute distinctions, which they must be so constantly tempted to draw in confining their attention so exclusively to one disease; distinctions which few have an opportunity ever afforded them of learning with any degree of accuracy, and which, when learnt, have not a tithe of the value of information obtained with so much more ease and so much greater certainty from the patient's own lips, in the history of the incursion of the malady and the general state of his health.

I find Dr. Thompson set out with the assertion that doubtless much confusion has arisen from the use of inaccurate terms; and he announces that, though what

make any violent changes in nomenclature, he would feel no hesitation in displacing terms that are obviously inaccurate. I was therefore rather surprised to find, as I proceeded, the more inaccurate term "rhonchus" universally substituted for the more allowable one of "râle", which has at least the merit of reminding us of our obligation to that great master-mind who traced out the path in which he now finds so many followers, and which has also the reasonable defence which Laennec himself set up for it when he adopted it,—that it was a generalisation of a well-known and popular phrase, the "death-rattle", as applied to sounds generated by the meeting of air and fluid in the air-passages. Still greater was my astonishment, as I proceeded, to find a justification attempted to be set up for the word rhonchus, ending, too, with a couple of lines from the Greek! I much doubt if there be any analogy between the loud-booming roar of the ocean, as it dashes in its majesty against some headland cliff, and the tiny rattles heard in the minute bronchial tubes. It is evident that Dr. Thompson had in his mind the beautiful description of the aged priest of Apollo, as he wandered weeping along the shore, and heard the splashing of the waters as they broke in foam over the pebbly beach; but how different the language!

A document such as this, coming from one of the physicians of the Hospital for Consumption, issues, as it were, *cum privilegio*, or at least with some degree of authority; and, therefore, I trust my friend Dr. Thompson will forgive me, if I quarrel with his affixing the sterling stamp to baser metal. The pages of Dr. Walsh's most able and comprehensive treatise are crowded with terms infinitely more objectionable; but their very number and variety, their utter defiance of all euphony and philology, will alone prevent their ever coming into general use.

The term crepitation, as happily devised by the author of auscultation, need not be superseded, as it cannot probably be improved upon; but the definition given in the paper we are considering, "numerous, minute, similar, rapid puffs", conveys to my mind no idea of its character. A puff (*vide* Johnson) is a small blast of air; and the term might be not inappropriately applied to the blowing or whiffing breath-sound which often accompanies crepitation, but has no analogy with the minute crackling which constitutes the sound itself. The term "râle sous-crepitant" is in perfect analogy, according to the theory then entertained of the formation of both sounds, with the classical and legitimate employment of the prefix "sub": thus "subraucus" is somewhat hoarse, and subcrepitant would mean somewhat crepitant, and was applied to a mucous rattle which approached to the character of crepitation. I am not sure that Laennec employed the word "sous-muqueux"; but if he did, it stood in the same relation to the "râle muqueux", just as "sub-humidus" is somewhat moist. The "râle crepitant" stood at one end of the scale, the "râle muqueux" at the other, of a series of sounds, which were all supposed to be produced in the same way, and the varieties were described as "crepitant", "sous-crepitant", "sous-muqueux", "muqueux". All this is objectionable, because conveying a theory, which, as Dr. Thompson has shown, our present views lead us to believe to be untrue.

I remember when at school being sorely puzzled by the phrase "simplex munditiis"; its meaning, however, has not been forgotten, and it is much to be wished that physicians, who by their position and their eminence give the tone to our medical nomenclature, would bear it in mind. In the application of auscultation to diseases of the lungs, we have no need to travel beyond our own language; and for some time I have been in the habit of employing terms the most simple, in attempting to convey to the junior students at St. George's Hospital ideas of what they hear in listening to the chest. The word "sound" in its various combinations easily supersedes the more perplexing terms of rhonchus and râle, and the more ugly names of rattle or noise. We have then, the breath-sound, and the voice-sound, the natural, the diminished or the weak breath-sound; or we have it exaggerated, loud or harsh. Then again we have the inspiratory sound and the expiratory sound in all their various

relations: and these may be qualified as shortened, prolonged, blowing, whiffing, loud, very loud and blowing, metallic. Such terms avoid all exposition of a theory, such as are more generally conveyed in the use of bronchial, cavernous, or amphoric, of which the last is the least objectionable. Exactly the same forms of expression may be applied to the voice-sound: it may be weak, exaggerated, or loud; it may have a metallic or an amphoric tone; it may be ringing, squeaking, or quavering. I am afraid we shall not get rid of the term *ægophony*; and yet constant errors in diagnosis are due to its employment.

Coming now to those cases in which the terms rhonchus and râle are used, it appears to me that we cannot improve upon crepitation, expressing thereby that sound which most nearly resembles rubbing the hair between the finger and thumb near to the ear; and if people choose, it may be called fine or coarse, although I have often observed in the same case, that what one man calls fine, another calls coarse. Then, abolishing the terms subcrepitant, submucous, and mucous, we simply substitute the terms fine and coarse moist sounds, which naturally merge into rattling, bubbling, or gurgling moist sounds. Clicks, moist clicks, or clicking sounds, express another variety, where the intervals are more or less prolonged between each individual explosion, which together make up the sum of the moist sound. Crackling and crumpling sounds are also each of them sufficiently expressive. Sonorous sounds are either grave or shrill, and individual observers may indulge their fancy in calling them whistling, cooing, snoring, and the like. Nor is there any difficulty in describing the combination of crepitation and moist sounds, which has given rise to the unintelligible phraseology referred to by Dr. Thompson, of mucocrepitant rhonchus. So also we may have clicks and moist sounds together, or sonorous and moist sounds together.

If Dr. Thompson will allow me to suggest these emendations, I trust he will also allow me to add my small meed of commendation to the attempt he has made to simplify this mode of diagnosis.

Bruton Street, Berkeley Square, May 3rd, 1853.

PERISCOPIC REVIEW.

MIDWIFERY AND DISEASES OF WOMEN.

NEW OPERATION FOR THE CURE OF PROLAPSUS UTERI.

M. DESGRANGES, senior surgeon of the Hôtel-Dieu at Lyons, has published an account of a new operation for the cure of prolapsus uteri in the *Gazette Médicale de Paris* for January 29th, and February 12th and 26th.

He defines a radical cure in such cases to consist in replacing the uterus in the pelvis, maintaining it there without the aid of apparatus, and in doing nothing which may compromise life, or even the functions of the organ; in attempting nothing which, if it fail, would render the disorder more severe than before. These indications he believes he has fulfilled, after three years of observation and experiment.

The author first briefly reviews the various operations which have been proposed for the treatment of prolapsus uteri.

NARROWING OF THE VAGINA. Cauterization. In 1823, M. R. Gérardin proposed to form contractile cicatrices, and thus to narrow the vagina, and increase the resistance of its walls. He went still further, and advised the complete obliteration of the canal. In 1833, Professor Laugier employed cauterisation with acid nitrate of mercury. In 1835, M. Velpeau applied the actual cautery. The objections to cauterisation are, the difficulty, especially with the actual cautery, of limiting the extent of the part acted on; and the danger of injuring neighbouring organs, which renders it necessary to cauterise superficially, and hence often insufficiently. Success, however, may be expected from cauterisation in a few cases; but it requires to be carried further than prudence allows.

Excision. Drs. Heming and Marshall Hall propose the removal of an elliptical piece from the anterior wall of the va-

gina; the edges being immediately united by suture. Mr. Ireland recommends the removal of a quadrilateral flap on each side. M. Velpeau prefers removing pieces both before and behind, so as to treat the rectocele and cystocele, which he observes to habitually accompany prolapsus uteri. In the few cases in which excision has been practised, the prolapsus has returned in a few months. The tediousness and difficulty of this operation, its liability to injure the bladder or rectum, and the chance of purulent infection, are objections to its performance.

Suture. M. Bellini, an Italian surgeon, proposes to include a fold of the vagina in a suture, so as to produce sloughing. But the fold may be too deep; hemorrhage may be produced; or the long presence of the sloughs may irritate the organs, and expose the patient to the risk of purulent infection.

NARROWING OF THE VULVA. Dieffenbach excised a series of longitudinal folds round the orifice of the vagina. But this only converts complete into partial prolapsus; and this would be a great point gained, if the patients were freed from the pain produced by displaced uterus at the same time as from the projecting tumour. The merit of the operation is, however, doubtful. M. Malgaigne believed that the excision of the anterior or the posterior semicircumference of the vagina would be of more advantage than other methods; but the only case on which he operated in this way was unsuccessful.

Fricke of Hamburg proposed to unite the walls of the vulva. He pared the internal faces of the labia majora, and united them by suture, as in perineorraphy. Care must be taken to have an aperture behind for the passage of fluids, and one in front for the performance of the generative functions. The uterus is thus sustained by an artificial floor; but this is too low, and the radical cure is only the substitution of one grave infirmity for another.

All these modes of operation M. Desgranges believes incapable of fulfilling the object intended, while several of them are likely to produce danger. The opinion of M. Moreau, that pregnancy is a remedy for prolapsus, he answers by the statement that he has always seen it augmented after labour in persons in whom it previously existed.

The instruments used by M. Desgranges are small self-closing curved forceps, furnished at the end with projecting teeth; a holder resembling a pair of lithotomy forceps, but having the end of one branch channeled, for the purpose of applying the small curved forceps; a trivalve speculum; a lithotomy gorget; a pessary to distend the vagina; and a double T bandage.

OPERATION. The patient, having been prepared by rest, bathing, gentle purgatives, and an enema, is placed on her back, with her thighs widely separated. The trivalve speculum is then introduced, with the handle turned towards the pubis, and the valves are separated to a circumference of about six inches. The vagina usually projects between the blades; but sometimes, when the tissue is less lax, it remains stretched. The cervix uteri must be carefully looked for, as it may lie between the valves of the speculum, like the portions of the vaginal wall.

Through the speculum, the vaginal forceps, with strings passed through their handles, are introduced by means of the holder; and, by strongly pressing on the handles of the latter, the blades of the forceps are separated. They are then placed on the projecting membrane of the vagina; and, by relaxing the hold of the handles, they are made to take firm hold of the tissues. Each projection between the blades of the speculum, or, as is sometimes found, each flat portion between them, may receive two or three of these forceps, so that from six to nine altogether are applied. The speculum being withdrawn, the pessary is introduced, and is firmly fixed by means of some turns of a double T bandage, of which the vertical bands meet the transverse one at the level of the hypogastrium: each of the vertical bands turns over the upper part of the thigh, to rest on the great trochanter. The string which attaches the pessary to the bandages ought to be rather behind than in front, as the passage of urine may otherwise be impeded or prevented by the pressure of the urethra against the pubis. The strings attached to the forceps are collected, tied together, and fastened to the bandage. The patient is then put to bed, and perfect rest is enjoined. The forceps generally fall off from the fifth to the tenth day, sooner or later, according to the size of the fold of membrane which they have seized.

This operation is repeated on other parts of the vagina, the speculum being employed until the walls no longer project between its valves, or its being opened causes pain or hemorrhage. The gorget or finger must then serve as a conductor. The gorget is passed in on the finger to the part intended to be operated on, and is turned with its convexity towards the vaginal wall. The vaginal forceps, fixed in the

holder, are then introduced along the groove in the gorget. When they have arrived at the end, the conductor is withdrawn, and the forceps are made to seize the membrane. When the finger is used, the forceps are introduced along it, taking care that the finger be not wounded. On arriving at the destined spot, the blades are separated, and pressed against the vaginal wall.

The instrument is most easily applied on the posterior wall of the vagina; with more difficulty on the lateral walls; but, in regard of importance, the lateral walls have the preference. M. Desgranges has never made more than ten applications of the instrument. He says, that the surgeon must be guided by circumstances in judging of the proper number of applications, but that it is better to make too many than not enough.

The pain, he says, is not great, unless the cervix uteri be seized: pain then is severe, radiating to the loins and abdomen. The free extremities of the forceps may cause excoriations, unless the tissues be protected by diachylon plaster.

Results of the Operation. The febrile reaction is slight, and of short duration; and requires no treatment beyond low diet.

When the forceps have fallen off, a small suppurating wound is left. By digital examination, small hemispherical projections are felt, varying from the size of a pea to that of half a nut.

The vagina gradually loses its calibre and its mobility. At a later period, it becomes covered with nodular bands; the narrowing goes on until the finger can scarcely be introduced without a disagreeable sensation. In process of time, the nodosities become smaller, and even disappear; the vagina regains its suppleness, and, with the exception of its calibre, it returns far towards the normal state. The cervix is in the axis of the vagina; and the contraction affords no impediment to coitus or to delivery, as has been proved in one case.

PROLAPSUS OF THE UTERUS AND VAGINA DURING PREGNANCY AND LABOUR.

The *Dublin Quarterly Journal of Medical Science* for May 1853, contains a paper on the above subject by Mr. J. H. Houghton, of which the following is an abstract.

CASE. Mrs. S., aged about 26, had been much neglected in her first confinement, and had since suffered from prolapsus uteri. About November 1850, she had retroversion of the uterus, followed by a miscarriage at the fourth month: since which time the uterus had descended daily, and had prolapsed every day during her present pregnancy, even to the day of her delivery. At times she had had considerable discharge from it; and she was aware of ulceration existing round the os. She had not had any medical advice for the prolapsus.

She was taken in labour with her second child, on November 13th, 1851, at 4 P.M. The pains continued feeble and infrequent till 2 P.M. the next day; and Mr. Houghton saw her at about 4. The head presented naturally; the os uteri was dilated to about the size of a crown-piece; the passages were moist; the membranes had been ruptured twenty-four hours previously. On examination, the os uteri was found close to the outlet; the walls of the uterus, from the margin of the os to that part of the uterus against which the head of the child pressed, formed a cone three inches long, the apex downwards. The lips of the os were very thick, rigid, and unyielding; and indeed the whole of the cone presented the same character. The pains were regular and tolerably strong. As the labour proceeded, the whole mass, uterus and head, came down together, dragging with it the anterior wall of the vagina, and at length obliterating the anterior *cul-de-sac* of the vagina; the tumour thus formed dilated the vulva. The descent continuing, and the os uteri scarcely dilating at all, the uterus came so low down that the anterior lip of the os uteri was pushed outside the vulva, and the anterior half of the os uteri and the posterior half of the vaginal orifice formed an elliptical opening, through which the child's head could be readily felt, and, if necessary, could have been seen. Still the os uteri continued firm and unyielding; and eventually the whole of the os, with an extraordinary *caput succedaneum*, protruded from the vagina.

Tartar emetic was given, and nausea kept up for about three hours. After this, two scruples of laudanum were administered.

At 8 P.M., the os uteri was rather larger than a crown-piece; the *caput succedaneum* protruded; the bones of the head pressed on the margins of the os, which were thick, hard, and very unyielding. The pains were strong. The anterior *cul-de-sac* of the vagina was obliterated with each pain, with a disposition of the whole os uteri to pass externally. For some time after the laudanum was given, the pains became more moderate, but they never ceased, and at 10 P.M. returned strongly. The os was now more disposed to dilate, though still very firm and rigid.

Mr. Houghton determined to wait for dilatation, and in the mean time to prevent total inversion of the vagina. To effect this, he proceeded in the following manner. Having replaced the uterus and vagina as well as he could, he watched carefully for each pain; and when it was about to commence, he passed the fingers of his right hand into the anterior *cul-de-sac* of the vagina, and the thumb of the same hand into the posterior *cul-de-sac*. The fingers and thumb thus embraced the os and the child's head; and while the latter was allowed to press on and dilate the former, he supported the whole mass in position, or nearly so. For some time the dilatation continued very slowly, and he could feel, from time to time, that abrasion of the anterior and posterior lips of the os had taken place. The os now very tightly embraced the head, the posterior lip being softish, the anterior very hard and thick. At about half-past 11 p.m., during a very strong pain, Mr. Houghton felt something suddenly give way, and the child was almost immediately born alive; laceration of the posterior lip of the os uteri having taken place to the extent of about an inch. No flooding followed. The uterus and vagina were prolapsed when the placenta was expelled. The uterus was easily returned; the patient was much exhausted; a stimulant and a dose of opium were given, and she was allowed to rest.

The patient went on favourably; but remained subject to prolapsus, which returned every time she sat up.

Prolapsus of the uterus during pregnancy and labour is a rare disease. Mr. Houghton collects six cases from a paper published by Dr. Merriman in the *Medical Times*, six related by Dr. D. D. Davis, in his *Principles and Practice of Obstetric Medicine*, and two cases recorded by Dr. Ashwell, one of which is from Capuron.

From a review of these fourteen cases, Mr. Houghton finds:

That two cases were primiparae; four multiparae; while in eight the number of pregnancies was not named. That in two cases the head presented; in twelve the presentation was not named. That in four cases there was great rigidity of the os; in ten, the state of the os was not mentioned. That in thirteen the prolapsus was complete; in one, this was not mentioned. That in one case venesection, tartar emetic, and opium, remedies calculated to remove rigidity, were used with benefit; in four, counter-pressure was used; in four, dilatation; in four, the mode of proceeding is not clearly related; in two, incisions were practised; in one, turning. In twelve cases the patients recovered (probably with prolapsus uteri remaining); in one, death occurred; in one, recovery without prolapsus. Rupture of the cervix uteri took place in one case.

The accounts of treatment of the disease are very meagre. Counter-pressure, dilatation, and incision, were the means most practised.

Counter-pressure seems applicable in all cases of prolapsus during labour; for on seeing the uterus and vagina protruded, and reflecting how the uterus is naturally suspended in the pelvis, it follows that by supporting the vagina with the tips of the fingers, and thus maintaining its *cul-de-sac*, a point is afforded from which the child or the membranes may press on and dilate the os.

Mechanical dilatation is objected to by Mr. Houghton, on the grounds that by its performance a risk is incurred of stimulating the reflex function of the uterus, and hence producing violent uterine action, and laceration of the cervix or body of the uterus.

Incision of the cervix is recommended by Mr. Houghton to be employed, after counter-pressure has been continued some time, and rigidity continues in spite of the ordinary means of overcoming it.

STOMATITIS MATERNA: ITS CAUSES, VARIETIES, AND TREATMENT.

In the Periscopic Review of our number for March 11th, p. 218, we brought together the substance of several very interesting papers on the symptoms, anatomical lesions, and treatment of stomatitis materna; and, in consequence of our remarks, Dr. Cullen published, at p. 333 of our number for April 16, a case of the disease in question which occurred in his practice. We now return to the subject for the purpose of introducing to the notice of our readers a paper "On Stomatitis Materna," by W. H. BYFORD, M.D., Professor of Medicine in Evansville Medical College, U.S., which appears in the April number of the *American Journal of the Medical Sciences*.

Dr. Byford regards the inflammation of the mouth as a symptom of a general disorder of the whole system, depending most

probably on an abnormal condition of the blood. On this point he remarks:—

"Could we see all the vital and chemical changes produced in the blood—for changes there must be—by the efforts of the mother's system to sustain the child *in utero*, and the necessary mutation after the process of gestation is completed, compared with its condition in health and during lactation, we might receive some light upon the subject. I apprehend that we should be taught that the character, in some respects, of change in the blood itself, would be continuously the same from the commencement of gestation to the termination of lactation; and that the effect upon the mother's energies would correspond with the quantity of the peculiar change growing out of the increasing wants of the being dependent upon her for support. And as anæmia is one of the results of protracted lactation, this tendency may begin with the commencement of pregnancy. Patients not very competent to the task of childbearing and its consequences, however, often become enfeebled and thin in gestation, and continue to become more so until they succumb, or are relieved from the discharge of these duties. The same nourishing principle called for to sustain the child *in utero*, is still demanded to nourish it at the breast; and it may be a secretion in the first place, similar in character (possibly identical) to what it is in the last. This demand increases as the child grows in size and vigour, and must consist of the proximate elements of nutrition so nearly vitalized as to require none in the first instance, and, in the second, but feeble powers of digestion to render them subservient to their appropriate uses. If the pathological condition of the system is that of anæmia resulting from pregnancy and lactation, there must be some peculiarity about it, judging from its effects, differing from anæmia arising from other causes. And this may be the peculiarity, viz., a greater paucity comparatively, perhaps, than in any other case of anæmia of the material elements expended in the process of nutrition. And this may be the case without any of the ordinary signs of anæmia. From what has been said above, it may be inferred that pregnancy, as well as lactation, is regarded by me as one of the causes of stomatitis materna."

Dr. Byford considers extreme youth, the scrofulous diathesis, and debility, as predisposing conditions; and he also attributes great importance to extrinsic causes, namely, epidemic and endemic influences. The remarks upon this branch of the subject are of peculiar interest as general pathological observations, as they show the fundamental error which special pathologists commit when they labour to establish the characteristic distinctions of fevers, without at the same time pointing out what is equally important, their essential identity, and the meteorological and other causes which induce in them a change of features. This line of thought we hope to pursue on future occasions. In the mean time, the reader is requested to mark the general application of the following extract, as well as its bearing upon stomatitis materna:—

"By the epidemic influence, I mean the extensive change which has taken place in the general cast of the diseases of the West, especially along the course of the large rivers, from the ordinary endemic bilious fevers, and other miasmatic diseases, to the typhoid or continuous type, attended for the most part with affections of the mucous membranes, particularly of the alimentary canal. This typhoid diathesis is so remarkably developed in many parts of this extensive tract of country, that it has usurped the place of the former diseases, or moulded them into a different type. The western physician of many years' experience can remember that in many extensive sections of country nothing was known from observation, until within a few years past, of the typhoid or continued fever. Taking these things into consideration, I think it may be inferred that a widespread epidemic influence has been for some time exerting its force upon the inhabitants of this portion of the country, producing a condition of the system in which there is a strong proclivity to disease of the mucous surface; and operating upon the maternal system, its effects are the tendency to this disease, just as in particular seasons, and under certain circumstances, there is a tendency to puerperal fever."

VARIETIES. Dr. Byford describes three varieties of the disease; and the following is a summary of his descriptions.

First variety. It is characterized by an erythematous inflammation, which may be either confined to one spot, or more or less diffused over the mucous surface of the mouth and fauces. This may pass away in a few hours, but it more generally continues for some days, after which it generally subsides, leaving the patient apparently quite well, with the exception of a little debility. Sometimes there is only a remission, and not a com-

plete relief from the soreness and distress. After an uncertain interval, a similar train of symptoms occur.

Second variety. It seems to engraft itself upon and to alternate with the first variety. A crop of vesicles is scattered over a part or the whole of the inflamed surface. The vesicles are sometimes transparent, and easily overlooked; sometimes aphthous, and quite obvious. The paroxysm is more severe, and more protracted. The respite from suffering is commonly shorter, and less complete.

Third variety. The whole force of the paroxysm is concentrated upon a small part of the surface; always, in Dr. Byford's experience, upon the tongue. Either upon its side or inferior surface, he has seen it begin by a fissure, gradually leaving an ulcer, from a hardened tubercle, from the bursting of a vesicle, or simply from an inflamed point. A rapid ulceration deeply notches the tongue: suddenly the ulceration ceases, and the cavity granulates; but the tongue is left distorted. Fresh paroxysms occur, as in the former varieties. Notwithstanding the severity of the ulceration, the constitutional symptoms are milder in the third than in the first and second varieties.

In our former notice, we mentioned that authors described the extension of the inflammation from the buccal mucous membrane to the bowels, as giving rise to diarrhoea, and we quoted a case reported by Dr. Hubbard, in which the following sentence occurs: "She complained of heat in the stomach, and colicky pains. The fecal discharges were solid, but more or less coated by a jelly-like substance, and that often spotted with dots of blood." We find in Dr. Byford's paper more precise statements as to the migrations of the inflammation from the mouth. He says:—

"The two first varieties are migratory, travelling from the mouth along the surface of the mucous membrane to all the neighbouring cavities, down through the pharynx and oesophagus to the stomach; and thence through the whole extent of the alimentary canal, frequently finding permanent lodgment in some section of this extensive tube, and destroying the patient by originating chronic gastritis, duodenitis, ileitis, etc., or passing through the larynx, trachea, and into the bronchia. And if it does not, by establishing inflammation in some portion of these tubes, exhaust the patient, it may awaken into existence the more fatal affections of the substance of the lungs. It has also followed the nasal passages into the different cavities of the skull, or maxillary antrum, and there induced permanent inflammation. At other times it travels through the Eustachian tube to the tympanum, and thence to the mastoid cells. And I have seen one case where permanent deafness of one ear, and exfoliation of bone from the mastoid process, occurred. The most common course for it to take is into the alimentary canal and lungs. It is very prone to fasten fatal disease upon the lungs, when it is allowed to run on for any considerable length of time."

TREATMENT. Ferruginous tonics, nutritious diet, and cod-liver oil, are the best remedies in the opinion of Dr. Byford. Change of residence, and weaning (in common with most authors), he considers more conducive to recovery than any medicines. With regard to weaning, he says: "In some cases weaning will not in itself cure, although this is the general rule."

TRANSVERSE PRESENTATION: DELIVERY BY EVISCERATION AND DECAPITATION OF THE FÆTUS.

Blundell [ed. 1840. p. 153], speaking of Embryotomy, says:—"We may attempt the abstraction of the child in two ways: by decapitation, or by disruption of the different cavities. For opening the cavities, the best instrument, I suppose, is a long and large perforator. It is to be introduced at the thorax in the arm presentation, which is the most common;—the viscera being afterwards removed at the opening, so as to make room for the introduction of the hand, and the seizure of the feet. But although a fetus may be removed in this manner, I suspect that extraction by decapitation, when this can be accomplished, is decidedly to be preferred—a practice first recommended by Horne, and recorded, I think, by Heister. For this purpose I should prefer (to a semilunar knife with cutting edge) a blunt hook of soft iron (not of steel) mounted on a stem, firm yet flexible, so that in operating, the curve might be accommodated to the situation of parts. This hook is to be fixed over the neck; and then by drawing resolutely but rationally, the head is to be torn from the body. The body of the fetus is then to be abstracted by the arm; and the head afterwards removed separately from the uterus."

The points of importance connected with decapitation are the

difficulty of removing the separated head; and the danger of injuring the mother by using a cutting instrument of improper construction. In the following case the scalpel was probably employed from necessity, and not from choice. We quote from the "Proceedings of the Records of the Boston Society for Medical Improvement" as reported at p. 372 of the *Amer. Jour. of the Med. Sciences* for April 1853.

"CASE REPORTED BY DR. GRAY. A patient, somewhat over thirty years of age, was taken in labour of her first child in the early part of November 1852. At the end of thirty-six hours, the left hand and arm were found protruding externally, and the head which was in the hollow of the sacrum was forcibly pressed against the sternum. Under these circumstances, turning being out of the question, evisceration was at once resorted to. The presenting arm, nearly filling the vulva, was removed at the shoulder; a cord wound round the finger, and thus passed completely over the neck, served to bring the child sufficiently low to render evisceration of the thorax comparatively easy. This operation being finished together with the removal of several bones, the child, even though propelled by violent pains, made but little progress; and after assiduous efforts for a period of two hours, decapitation was decided on. The neck being drawn fully into view by the cord, was readily divided by a scalpel. The body by means of the remaining hand was easily withdrawn, and the head as readily followed from the vagina—the operator's fingers being introduced without difficulty to bring it away. The head was of the usual size, and the child was a large one."

"Dr. STORER thought this a remarkably favourable result. He alluded to the great difficulty uniformly experienced in removing the separated head. He knew of but two cases, besides the one reported by Dr. Gray, having occurred in Boston: one was attended by Dr. Channing, and for a long time efforts at removing the head were unsuccessful. Dr. C. removed it on the succeeding day. In his own recently reported case, Dr. Storer had stated that he used great exertions for half an hour after the attending physicians were exhausted, and only continued his efforts from a desire to free them from any odium likely to follow were the head left in the uterus. He had then succeeded."

THE DISASTROUS RESULTS OF IGNORANT AND VIOLENT INTERFERENCE WITH THE PROCESS OF PARTURITION.

In this country, we have still to deplore an unnecessary mortality among puerperal women, from the violent interference of ignorant midwives and untaught practitioners, during natural as well as during preternatural labour. This subject has been forcibly brought before the readers of the *ASSOCIATION JOURNAL* by Dr. MURPHY, in his Lettsomian Lectures, published in the numbers for March 25th, April 8th and 15th. The following account, by Dr. W. S. KING, of the native midwifery of Monterey, in California, presents a more appalling picture, and on a larger scale, of meddlesome midwifery, and its direful consequences, than anything which we can recollect having read of in any other work. We quote from a paper on the "Medical Topography, Climate, and Diseases of Monterey, California," in the *American Journal of the Med. Sciences* for April, p. 301:—

"The diseases peculiar to females are far more common in Monterey than any other class of disorders. Of these, the most usual are leucorrhœa, prolapsus uteri, and deranged menstruation. Those affections are more numerous in proportion to the population in Monterey than in any community I have ever known."

"The two first mentioned are, I believe, owing to the mode of treating parturient women practised by the natives of this place. It is the custom in Monterey, when labour begins, to place the woman on a chair in the middle of the room; a rope is fastened to the rafters above her head, which she is directed to pull. Round her abdomen a broad towel or rebosa is passed, the ends crossed behind, and intrusted to assistants, who are instructed to tighten it when the abdominal tumour descends during the pain, and *belay there* (as it were) until the arrival of the next, when it is *hauled taut* again, so as to hold on each time to the progress made, and not permit the usual ascent of the tumour after the subsidence of the pain. With the same view, a strong man is frequently seated behind the woman, who, with his hands placed on her abdomen, makes strong pressure downwards at each pain, with the idea of assisting, by mechanical force, the contractions of the uterus. All this time, the midwife (generally some old woman) is seated in front with one, and, if possible, both hands in the vagina, making all the

traction in her power. When the woman and assistants are somewhat fatigued, she is placed upon her knees on the floor, but without relaxing any of the means and appliances which would cause them to lose the advantage already gained.

"These measures often prove fatal to both mother and child; usually, on the termination of the labour, the female is completely exhausted. From the injury done to the soft parts by the long and rough handling, ulceration and inflammation often ensue; thus laying the foundation of uterine and vaginal diseases, with displacement of the uterus.

"Immediately after the delivery, and when the poor woman is nearly worn out, and in a more or less excited state, and the nervous system in an exceedingly susceptible condition, and disposed to receive strong impressions from slight causes, it is the universal custom for all acquaintances, however slight, to visit, with one accord, the new mother; so that her room will resemble an evening party, being filled with numerous guests, who do not hesitate to sit for hours, in loud conversation, and regale themselves in smoking paper cigarettes. When we consider how much lying-in women often suffer from not being kept in a tranquil and quiet state after confinement, and how important to her well-doing is rest and exclusion of company, we may readily conceive the unfortunate result of an opposite course, and understand why more untoward circumstances happen with such women here than ordinarily.

"Within the last four years, the influence of the intelligent physician, and a few American families, have made some improvement in these matters; but, as this part of the profession is still in the hands of the Californian midwife, much ignorance and superstition still exist throughout the country, to an extent that could scarcely be credited in other portions of the United States."

ASSOCIATION INTELLIGENCE.

MR. SYME AND THE CENTRAL COUNCIL.

At a meeting of the Central Council, held at Worcester, on the 30th April, was read the following letter from Mr. Syme, of Edinburgh:—

"Edinburgh, April 22nd, 1853.

"SIR,—I beg to direct your attention to the 158th page of the 19th volume of the Transactions of the Association just published. As it is impossible for me to remain connected with a body which could tolerate such a statement, or sanction its publication, I must desire my name to be withdrawn from the list of associates.

I am, etc.,

"JAMES SYME."

To the President.

It was then resolved—

"That this Council receive with regret the resignation of Mr. Syme; but at the same time they beg to impress upon him that the passage complained of in the address was read at the anniversary meeting by Mr. Hester; and that, therefore, this Council have had no choice but to carry out the instructions of their superior body, viz., the members assembled in general meeting."

JAMES P. SHEPPARD,
Secretary to the Association.

April 30th, 1853.

ANNUAL MEETING OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

The members and friends of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION are informed that the Twenty-first Anniversary Meeting of the Association will be held at SWANSEA, on WEDNESDAY, the 10th, and THURSDAY, the 11th of August next.

Full particulars will be forwarded to the Editor for publication in an early number of the Journal.

JAMES P. SHEPPARD,
Secretary to the Association.

May 7th, 1853.

METROPOLITAN COUNTIES BRANCH.

A meeting of this Branch was held on Tuesday, the 10th instant, at 4 P.M., at 37, Great Queen Street, Lincoln's Inn Fields. It was summoned by the Council, to consider Dr. Cormack's proposal to hold Quarterly Meetings of the Branch, and also for the consideration of general business.

MEETINGS OF THE BRANCH: ALTERATION OF RULE XI.

Dr. CORMACK proposed a resolution providing for three general meetings during the year, in addition to the annual general meeting.

Mr. RICHARDSON seconded the resolution.

Mr. BOWLING doubted very much the judiciousness of Dr. Cormack's proposal. Medical men left home with difficulty; and he did not think that good meetings could be obtained, if they were held so frequently. He urged Dr. Cormack to reconsider his proposal. When there was business to be transacted, the Council could at any time call a meeting. Would Dr. Cormack be satisfied with two meetings?

Mr. COLLYNS, from his experience in the South Western Branch, to which he formerly belonged, was convinced that it would be difficult to get a good quarterly attendance.

Dr. G. WEBSTER said, that these were stirring times, and that the profession expected the members of this Branch, who could assemble so much more easily than those living scattered at great distances in the country, to meet for the discussion of the questions of the day. There was no other society in London where the economics of the profession could be debated. He would support Dr. Cormack's motion.

The PRESIDENT thought that, without business, quarterly meetings would involve needless expense. Unless notices were sent, members forgot that there was to be a meeting; and notices involved a large postage expenditure. He had only accidentally remembered to-day's meeting from seeing an allusion to it in the Journal of last week.

Mr. CHARLES hoped that Dr. Cormack would neither withdraw nor modify his proposal. There were several most important questions of professional polity upon which the Branch ought to deliberate, not once only, but frequently. "Advice gratis" and "hospital abuses," which had been so well handled in the Journal, ought to engage the attention of an early meeting of this Branch.

After some conversation, the motion was ultimately passed in the following modified form:—

"That the following do stand in place of Rule XI.

"That the annual general meeting be held on any Tuesday in June or July, and at any time or place which the Council may appoint, provided that not less than twenty-one days' intimation of the day, hour, and place of meeting, be given in the Journal; and that, in addition to the annual general meeting, two other general meetings be held annually in London, viz., on the second Tuesday in February, and the second Tuesday in May."

The object of appointing these meetings on the particular days specified was, that they would best afford the members an opportunity of considering with advantage any measures affecting the medical profession which might be before Parliament. By the days of meeting being fixed, members would be able to remember them, and make their arrangements accordingly.

MEDICAL REFORM.

Dr. SEMPLE thought it very necessary that members of the Association should take part in matters of importance connected with the profession. At the present moment, two measures were under consideration by the ministry, both of which affected very materially the interests of all practitioners of medicine and surgery. The first was the proposed new Charter of the Royal College of Physicians; and the second was the Medical Reform Bill proposed by the Association. With respect to the first measure, it was one of internal reform; and as such, the Association had probably little concern in its enactments; but it was nevertheless quite evident that, if it passed into a law, it would affect not only the members of the College of Physicians, but, in connexion with any coming measure of general medical reform, likewise all the practitioners of medicine throughout England and Wales. It was therefore necessary that a Committee should be appointed to examine how far the new Charter of the College would influence the great mass of the profession.

But the Association is more particularly interested in the Bill of Medical Reform brought forward by itself. Admitting as he (Dr. Semple) did the necessity for some measure of medical reform at the present crisis, he thought that there might be some parts of the bill liable to objection; and, at any rate, that its provisions should be open to discussion. A draft bill was drawn up last year; and it was generally understood that some modifications had lately been introduced; but the nature of these modifications has not yet transpired. It was also necessary that public meetings should be held, and that the views of the members of the Association, and of the profession gene-

rally, should be clearly understood. It was quite possible that some such meetings had taken place; but he (Dr. S.) had not heard of them, with the exception of one of the South Western Branch, an account of which was printed in the ASSOCIATION JOURNAL and *Medical Times* of last week. That Branch had expressed some strong objections to the Bill. Believing that something must be done, but that at the same time we should guard against hasty and rash legislation, he thought that the appointment of a Committee, to watch the progress of the reform question in general, would be the means of putting the Association in possession of every important step which might be taken by the government, or by the Houses of Parliament; and also of inviting an expression of opinion, both individually and collectively, on the part of the members of the Association, as well as of other members of the medical profession. He moved the following resolution:—

“That a committee be appointed to watch the progress of the Medical Reform question in the Houses of Parliament; to communicate with the Reform Committee of the Parent Association, and with other Medical Reform Committees; and to report its proceedings to this Branch.”

Dr. GEORGE WEBSTER seconded the motion. He thought that the more the Bill was discussed the better. He concurred in the suggestion of communicating with other Committees; and he thought that the Committee of the South Western Branch ought to be invited to meet the Committee of this Branch, or to correspond with it. From some experience in the subject of medical reform, he was convinced that, without full, cordial, and frank discussion, the opinions of the medical profession could never be brought into sufficient harmony to enable any bill to meet with general support. He, therefore, speaking as a member of the Medical Reform Committee of the Parent Association, would say—let every part of the bill be discussed here and throughout the kingdom; and if it contain any parts which are objectionable, let them by all means be altered. He would, however, remind the meeting that the subject is involved in immense difficulties. It is not as if they were legislating for the profession *de novo*: they were obliged to purchase the support of powerful interests by making concessions; and he felt assured that any one who had had any experience of the difficult negotiations which a settlement of this question involved, would pause before they blamed the Committee for in one or two points sanctioning what was not intrinsically best.

Dr. CORMACK proposed that Mr. G. Hastings, though not a member of the Association, being the Secretary of the General Reform Committee, be requested to take part in the discussion.

This proposition having been put by the President, was carried unanimously.

Dr. O'CONNOR thought that it would greatly facilitate the discussion, were Mr. Hastings at once to state to the meeting the present position of the Bill. He would ask, Is it likely to be introduced into the House of Lords, as intimated in the Journal for last week?

Some conversation ensued between Dr. O'Connor, Mr. Bowling, the President, and others; in the course of which it was stated, that many members of the Association were embarrassed from not having had it in their power to peruse the bill in its altered form.

Dr. DAVIES (of Hertford) would like to see the amended Bill printed in the Journal.

Mr. HASTINGS, having been called upon by the Chairman, then rose, and gave a history of the present position of the reform question, and of what had been done since the Oxford meeting.

He would reply to two statements made by Dr. Semple. In the first place, Dr. S. had stated that meetings of the Branches had not been held. Now, every one of the branches had met, and discussed the bill, and all except one had reported in its favour. The subject had also been brought forward at the last general meeting of the Association at Oxford. So that, so far from the bill not having been discussed, it had been extensively discussed. Secondly, Dr. Semple had said that very little had been done by the Committee since the draft bill was published in November 1852. This was a mistake. The Committee had exerted themselves in various ways—by correspondence with various bodies, and by deputations to the Scottish Colleges; in fact, they had done everything which they could with the view of rendering the bill acceptable to the corporate bodies, and to the mass of the profession. He did not, therefore, think that the Committee could be reproached with having been idle.

With regard to the present state of the bill, it had been found impossible for the Committee so to alter it as to meet the wants of all concerned within any reasonable time; and, under these

circumstances, it had been thought best to give it into the hands of Lord Palmerston in its existing condition, as it was published in the *Provincial Medical and Surgical Journal* for 10th November, reporting to him such alterations as might be from time to time suggested by the colleges and the profession. Lord Palmerston had expressed himself impressed with the importance of the subject; but he had since stated to Mr. Hastings that he had not time, being much occupied with Irish and other important parliamentary business, to give proper attention to it. He (Lord Palmerston) was willing that a deputation should wait upon Lord Aberdeen, and ask him to introduce the bill into the House of Lords, which was less occupied than the House of Commons. If introduced there, the bill would be discussed, and sent down to the Commons in a state which would probably give them very little trouble. He (Mr. Hastings) had written to Lord Aberdeen, requesting him to fix a day for receiving a deputation; and his lordship had fixed Thursday, May 12th, at two P.M., for that purpose. He would advise petitions of the form published at p. 390 of the Journal for last week, as an effectual means of bringing the subject of medical reform before the notice of the House of Lords. It would show to them that the subject was attracting the notice of the profession in general.

He agreed with the remarks of Dr. Webster, that the Association was in a different position from having to legislate *de novo*. Varying interests, and corporate bodies tenacious of their rights, had to be legislated for. It was evident that the Committee could not have everything as they liked; and the question was, whether the profession would accept a compromise. A bill opposed by all the corporate bodies could certainly not pass. But the present bill was supported by the College of Physicians; and this Mr. Hastings stated, notwithstanding assertions made to the contrary, on the faith of a letter which he had received from Dr. F. Hawkins, the Registrar of the College. The College of Surgeons had not acted so cordially: it evidently did not wish for any reform measure; but he did not think that parliament could throw over a bill which, though it did not meet all the views of the Council of the College of Surgeons, still proposed nothing injurious to it, and was acceptable to the mass of the profession.

It had been stated that the bill did not provide for the general practitioner. It did all that can be fairly asked for. When the bill became law, every one, even though only possessing the license of the Society of Apothecaries, would be entitled to be registered as a surgeon. Again, in future, every person admitted under the new act would be a member either of the College of Surgeons or the College of Physicians; and this would do away with any third grade—which, he believed, had been desired by the Association. The bill abolished a third grade, merely retaining the distinction between physicians and surgeons. With regard to education also: all members of the profession will have to enter through the same portal. Here again the system of equality is recognised; and the *status* of the general practitioner is raised.

In the formation of the Council, he allowed that there were points to which objections might be raised, and in which improvements might be introduced. It had been objected, that the Council was to be formed of the Regius Professors of Medicine in the Universities of Oxford and Cambridge, a member designated by the Senate of the University of London, the Presidents of the Royal Colleges of Surgeons and of Physicians in England, five physicians to be chosen by the College of Physicians, five surgeons to be chosen by the College of Surgeons, and of six other members, who may or may not be general practitioners. It would not be possible to place more members of this class on the Council; and he thought that the plan which had been proposed, of electing members of the Council by the whole profession, could not be adopted. It might work well for a year or two, but would ultimately lead to cliquism and other evil consequences. The committee thought that, as a compromise between the two systems, the Secretary of State should nominate the Council.

A great difficulty in all attempts at medical legislation had hitherto been the presence of clashing interests. Until the present occasion, he believed that England and Scotland had differed on the subject of medical reform. The Scottish bodies now propose to have, instead of a separate Council for each division of the kingdom, a single Council for all; and that their examiners should be chosen from the Colleges of Physicians and of Surgeons in Edinburgh, and the Faculty of Physicians and Surgeons in Glasgow; and that practitioners should be registered on passing the examination of the Board thus appointed.

The Colleges of Physicians and of Surgeons in Edinburgh had deputed their Presidents to attend the deputation which waited upon Lord Palmerston, and to express their concurrence in the bill. The Faculty of Physicians and Surgeons in Glasgow at first opposed the bill; but that opposition had now ceased. In Ireland there had been no objections raised: he did not therefore expect much opposition from that quarter.

In order that the bill should pass, an united effort on the part of the profession was necessary, and he hoped that the recommendation to petition, contained in the Journal of last week, would be extensively acted upon.

In reply to an observation from Mr. BOWLING,

Mr. HASTINGS said that the College of Surgeons had objected to the measure because the examiners to be appointed by the Bill would examine in surgery. They wished that all candidates should present themselves both before the College of Physicians and the College of Surgeons. He had, however, heard that the College of Surgeons would not object to a Board appointed jointly by the two Colleges.

Mr. BOWLING said that Mr. Hastings had not referred to the Society of Apothecaries; and he was anxious to know if the Committee had had any communications with them. It was of no small importance to know the sentiments of so influential a body.

Mr. HASTINGS said that he had sent different communications to the Society of Apothecaries; but he had not received from them in reply any expression of opinion as to the bill.

Dr. HALLEY said that the Society of Apothecaries had always expressed a willingness to give up their rights whenever they should be called upon to do so.

Mr. BOWLING said—yes, but only upon certain conditions; and they would never do so voluntarily, unless some machinery were provided that would equally, or to a greater extent, maintain the high standard of education of the general practitioners. He wished to ask Mr. Hastings whether the six practitioners on the Council were to be general practitioners?

Mr. HASTINGS said that the term employed was, "medical practitioners".

Dr. WEBSTER said, this was a point upon which there had been a good deal of discussion; and he thought it had been understood that the six practitioners were to be general practitioners. He would like to see a Council elected by the profession at large; but if that could not be obtained, he would much prefer that the Council was nominated by the government than by the medical corporations.

Mr. BOWLING said that there were various points of difficulty, and one of them was the registration as surgeons of persons who were only Licentiates of the Apothecaries' Society.

Dr. O'CONNOR was convinced that the examination at Apothecaries' Hall was more conducive to public safety than that at the Royal College of Surgeons. The examination of the College was no test of fitness for the discharge of any duty connected with the profession. A slight examination in surgery and anatomy was no protection to the public. The object of the College of Surgeons appeared to be to form two distinct classes; the one a superior grade, the consulting surgeons; the other an inferior grade, men to make and find work for the superior. Mr. South had told a candidate, that in a case of hernia it would be his duty, not to operate himself, but to send for a hospital surgeon.

Mr. RICHARDSON said that if the Branches had discussed the medical reform question, he had seen no reports of the proceedings. No such reports had appeared in the ASSOCIATION JOURNAL, or in the other medical periodicals.

Dr. WEBSTER. You will find reports of many discussions in the Journal of last year.

Mr. RICHARDSON said that might be quite true; but since these discussions had taken place a new bill had been brought forward; and, excepting the discussion reported in the Journal of last week of the proceedings at the meeting of the South Western branch, he had not seen a report of any Branch meeting at which the bill now in the hands of Lord Palmerston had been considered. He much feared that the promoters of this bill were too impatiently bent on pushing it through parliament; for he knew that in many parts of the country the principles of the bill were not comprehended; nor was there an adequate sense entertained of the numerous changes which would be effected on medical practice, should it become law. He thought that the best thing that could happen to the profession, would be a refusal on the part of Lord Aberdeen to proceed with the measure during the present session of parliament. So far as he understood the bill, its tendency would not be to elevate, but to degrade the general practitioners.

Dr. CORMACK wished to recal the meeting to the nature of the proposition which was before it, and which probably they were all disposed to sanction. The topics upon which Mr. Richardson had entered would, as a matter of course, receive ample consideration from any committee which might be this day appointed; and might afterwards be fully discussed at a general meeting, when a report of the Committee was given in. He therefore thought that, unless some objections could be urged to Dr. Semple's motion, much valuable time might be saved by passing it at once. He could not at all agree with what had fallen from his friend Mr. Richardson, as to the question not having been fully discussed by the Association. Since ever he (Dr. C.) had been a member, it was one of the topics which had most frequently met his eye in the Journal of the Association. It had been debated in all the Branches, and at various annual meetings. At the Oxford meeting, the bill had been very minutely considered; and the result of an animated discussion had been the unanimous conviction that it was the duty of all classes of medical reformers to merge their individual differences. It was upon this basis that the present Medical Reform Committee was selected: it was a committee which fairly represented all—even extreme—opinions; and for that very reason the results of its deliberations were peculiarly entitled to respect. He fully admitted, with previous speakers, that it would only be just and right that the profession should elect its own Council; but his conviction was, that any attempt, in the first instance, to insist upon this legitimate claim, would produce no other practical effect than complete obstruction to medical reform. The Colleges would not concede this point; and the Colleges were too strong to allow any measure to pass in opposition to their combined exertions. The Colleges were, however, every day becoming more liberal. The question then was, not what was theoretically best as regarded the composition of the proposed Council, but whether a compromise might not be accepted. He thought that the nomination of the Council by the government was a very fair compromise; and that it was a method which even had some advantages. However, as he had already said, the question before the meeting was the appointment of a Committee; and he would therefore suggest that the further discussion of the merits of the bill should be delayed till the report of that Committee was before them. In the meantime, it should be well understood that the General Reform Committee had been engaged in arrangements of the greatest difficulty and delicacy, and that many of them were sacrificing their own peculiar interests to secure the co-operation of the profession, in behalf of the best measure which could in the circumstances be obtained. The Committee represented all opinions; and upon that ground it commanded confidence. The exertions of its members deserved the gratitude of the profession.

Dr. SEMPLE's motion was put and carried.

Dr. SEMPLE then moved, that the following gentlemen be appointed members of the Committee, with powers to increase their number to twenty-five:—

The PRESIDENT.	R. P. COTTON, M.D., Clarges Street, Piccadilly.
The SECRETARY.	JOHN DAVIES, M.D., Hertford.
HENRY ANCELL, Esq., 3, Norfolk Crescent.	PATRICK FRASER, M.D., Guildford Street.
J. RISSDON BENNETT, M.D., 15, Finsbury Square.	ALEX. HENRY, M.D., Alfred Street, Bedford Square.
T. SNOW BECK, M.D., Langham Place.	C. F. J. LORD, Esq., Hampstead.
JOHN BOWLING, Esq., Hammer-smith.	WM. O'CONNOR, M.D., George Street, Portman Square.
CHARLES T. CARTER, Esq., Hadley.	B. W. RICHARDSON, Esq., Mortlake.
T. CHARLES, Esq., Holborn.	C. SHILLITO, Esq., Putney.
WM. COLLYNS, Esq., Harlow, Essex.	F. SIBSON, M.D., Brook Street, Hanover Square.*
J. R. CORMACK, M.D., Putney.	

Dr. FRASER seconded the motion; and in doing so proposed that Dr. Semple's name should be added to the list; and that he should be Chairman of the Committee.

Dr. O'CONNOR moved:—

"That the Committee now appointed be empowered to call a general meeting of the members of the Branch, when they think it expedient, to report the result of their labours."

Mr. CHARLES seconded the motion.

The PRESIDENT had some doubts as to such a motion being in order: but after some discussion, it was put, and unanimously carried.

* When the Committee is completed, we will publish the additional names.

COMPULSORY VACCINATION BILL.

Dr. CORMACK said that the lateness of the hour would oblige him to omit much of what he had intended to state on the subject of the Vaccination Bill: but he thought that he could in a brief space of time say more than enough to justify the meeting in adopting the resolutions which he was about to propose. It was known to all present that Lord Lyttelton had introduced a compulsory vaccination bill into the House of Lords; and that it had actually passed the House of Lords, and was now before the House of Commons. He was willing to give the fullest possible credit to the philanthropy and patriotism of Lord Lyttelton, Lord Shaftesbury, and Lord Ellenborough, the noblemen who had most identified themselves with the measure; but patriotism and philanthropy were practically useless, unless they were supported by knowledge; and unfortunately, as regarded the vaccination bill, this was not the case. The promoters of the bill had become strongly impressed with the necessity of legislating for the repression of small-pox and the extension of vaccination; and they had startled the medical profession, from one end of the kingdom to another, by launching the present sweeping measure without affording to the profession any opportunity of expressing its opinion upon the complicated questions, political and medical, which were inseparably connected with it. If the medical profession had been consulted, it would most certainly have declared that, whether the principle of compulsion be politically sound or unsound, practicable or impracticable, there was another principle of far greater moment—an essential principle—which had been entirely overlooked. There was no provision in the bill to ensure efficient vaccination: and that was the first point to which legislation undoubtedly ought to be directed. A scheme must be devised for the abundant supply of good lymph: and for the conscientious and intelligent performance of the duty of vaccination. If time permitted, much more might be said upon this point: but he would just remark, that efficient vaccination could never be provided for except by obtaining the cordial support of the profession; whereas the effect of Lord Lyttelton's coercive measure was to irritate the profession.

If the measure was objectionable in principle, it was not less faulty in its details; which were, in some particulars, absolutely ridiculous. For example, in clause 1, we read as follows: "And such guardians and overseers shall require such medical officer and practitioners in all practicable cases to perform such vaccination in the presence of the parent or other person by whom any child may be brought to such place for such purpose *from the arm of a healthy child there present*; and where any such medical officer or practitioner shall not so perform vaccination as herein-before directed, he shall forthwith report the same, together with the reason thereof, to such guardians or overseers, who shall thereupon, if they shall not be satisfied with the reason so assigned, proceed, subject to the approval of the Poor Law Board, to take such measures as to them may seem fit for vacating the contract entered into with such medical officer or practitioner for the purpose of vaccination, or for enforcing the payment of any penalty provided for such case in such contract." No one who knew anything about vaccination could read the clause without smiling. A general system of vaccination can only be carried out by the use of dry lymph; and then, who are to be the umpires in disputed cases as to the healthy arm? The poor law guardians, forsooth, the cardinal point of whose sanitary creed is cheapness.

We might naturally suppose, that the House of Lords, in their liberal allotment of work and penalties to the medical profession, would at least not have excluded the idea of remuneration; but there is a special clause, (clause v,) which provides that there is to be no remuneration legally due for the highly responsible and very troublesome duties imposed by the act—duties which unquestionably require skill, patience, and integrity; qualities which ought to have some money-value in the eyes of the British Parliament; and which must in the end be so acknowledged, if the profession prove true to itself.

Clause VIII refers to the imposition of fines upon the parents and guardians of the unvaccinated: but what would be the result of enforcing fines upon poor people, who are generally the parties who show backwardness in having their children vaccinated? Why, if their goods were distrained, and they were cast into prison, the only result would be, that they would be converted into paupers; and there would be no economy in making such persons stipendiaries of the state.

Dr. CORMACK then moved the following resolutions:—

1. That the bill now before the House of Commons ought to be opposed by the public and the medical profession, upon the

grounds of its making no provision for efficient vaccination, and being crude and unworkable in its machinery.

2. That the following petition be sent for signature to the various towns within the bounds of the Metropolitan Counties Branch of the Provincial Medical and Surgical Association.

To the Honourable the Commons of Great Britain and Ireland in Parliament assembled.

The petition of the undersigned legally qualified medical practitioners resident in _____ and its vicinity, humbly sheweth,—

That your petitioners have learned that a Bill has been introduced into your honourable House for the extension of vaccination, by making it compulsory.

That your petitioners humbly beg leave to represent to your honourable House that a measure of so much importance to the community, so difficult of execution, and so intimately connected with medical science and medical interests, requires and deserves the most careful and enlightened consideration.

That the success of any measure of that nature must mainly depend upon the cordial concurrence, and the zealous co-operation of the medical profession.

Your petitioners, therefore, humbly but earnestly hope that neither the bill in question, nor any other of a like tendency, may receive the sanction of your honourable House, until the medical profession shall have had ample opportunity for considering its provisions, and expressing its feelings and opinions thereon.

That your petitioners beg leave most respectfully to urge on your honourable House the expediency of arresting further legislation on this subject, until a full and complete inquiry shall have been made into the causes which have led to the failure of the present Vaccination Extension Act, and into the best means of extending vaccination to the public, with a due regard to its efficiency, and to the just rights, feelings, and interests of the medical profession.

And your petitioners, as in duty bound, will ever pray, etc.

3. That a deputation from this Branch be appointed to wait upon the Secretary of State for the Home Department, to request him to refuse his support to any vaccination measure, till the medical profession has been consulted regarding its provisions, and till more information has been laid before the country upon the subject.

It was, he (Dr. C.) thought, peculiarly the duty of the profession to come forward at this juncture to stop the progress of this objectionable bill. It was, above all, incumbent on members of the Medical and Surgical Association to take every means in their power to prevent discredit being cast on the discovery of the immortal Jenner, and dishonour and injustice being done to the medical profession. The report of the Vaccination Committee of the Association was, up to this hour, the most valuable document which had yet appeared upon the vaccination question; and the body under whose auspices such a paper had been published, was well entitled to tell its sentiments to the government, the parliament, and the public.

There were also other bodies who could supply much useful information on the subject of vaccination, such as the Epidemiological Society, and other societies. The College of Physicians of Edinburgh had published a statement relating to the deficiency of medical practitioners in the Highlands and Islands. From this interesting document, (ordered to be printed by the College on the 3rd August 1852,) it appears that there is no machinery for vaccination which can be called into operation in the Highlands and Islands of Scotland, unless government came forward with a grant. Dr. Cormack then read the following passages, from the statement of the College of Physicians of Edinburgh, to which he had referred:—

"According to the population returns of 1841, the number of persons who never receive, and cannot, without great expense, at any time receive the benefit of medical aid, amounts to about 34,300; while those who receive it occasionally are in number about 90,000, making a total of 124,300 persons inadequately supplied. Doubtless, the numbers of these are almost daily becoming less by emigration; but it may be presumed that about 116,000 people, scattered over wide and rugged districts, are, at this moment, most imperfectly provided for in sickness.

"This destitution is at once a consequence and a proof of the miserably depressed social state of the Highlands. With the economics of that state, a College of Physicians has not a direct concern; but, whether the physical well-being of the people at large be considered, or the interests of the pro-

professional brethren who share the privations of the poor Highlanders, and help them to the best of their ability, it is conceived that the simple facts now brought out afford a sufficient apology for the College having made this attempt to bring the subject under the consideration of the public.

"The past history and present circumstances of Highland destitution forbid the hope that any such improvement in the social state of the people will be brought about within the present generation, as will enable them to provide medical aid for themselves; and, therefore, if relief is to be given at all, it must be from without.

"The scourge of small-pox may be kept in check by an increase of vaccinators in the Highlands, as it appears that many of the inhabitants are not protected by vaccination, so that, when they come into the Lowlands, they are peculiarly liable to suffer from small-pox: which fact is so well known to them that it not unfrequently prevents the poor from leaving home to seek for employment."

Dr. CORMACK concluded by urging his resolutions upon the meeting, upon the grounds that the profession had not been consulted, and that elements for enlightened legislation did not yet exist.

Dr. SEMPLE seconded the motion; which was unanimously carried.

Dr. CORMACK then proposed that the deputation to Lord Palmerston should consist of the President, Dr. Fraser, and Dr. Semple.

The PRESIDENT expressed his inability to form part of the deputation; and at his suggestion, his name was withdrawn, and that of Dr. Cormack substituted.

Dr. O'CONNOR seconded the motion in its amended form; and it was carried unanimously.

SCOTTISH UNIVERSITIES TEST BILL.

Dr. CORMACK thought that the Scottish Universities Test Bill, which had been brought into the House of Commons by the Lord Advocate (Moncrieff), was well entitled to the support of the medical profession; inasmuch as it would enable laymen to occupy the lay chairs of the Scottish Universities without subscribing allegiance to the doctrines and discipline of the established Church of Scotland. It was no argument in favour of these tests, that they were often subscribed by episcopalians and other dissenters in Scotland; and he thought that the medical profession were much indebted to the Lord Advocate for bringing in a measure which would open up the Scottish universities to members of the Church of England and of other churches, who are too conscientious to subscribe a creed which they did not believe. He therefore moved the adoption of the following petition:—

To the Honourable the Commons of Great Britain and Ireland in Parliament assembled.

The humble petition of the undersigned members of the Metropolitan Counties Branch of the Provincial Medical and Surgical Association,

SHKWEETH—

That your petitioners observe with much satisfaction the introduction of a bill into your Honourable House, "To regulate the admission of professors to the lay chairs in the Universities of Scotland".

Your petitioners earnestly pray your Honourable House to pass the same into a law.

And your petitioners will ever pray, etc.

Dr. HALLEY expressed concurrence in what had fallen from Dr. Cormack, and seconded his motion.

Dr. O'CONNOR said that every right feeling man must feel grateful to see a measure brought into Parliament, which would do away with great temptations to religious hypocrisy.

The PRESIDENT expressed his approval of the Lord Advocate's measure.

The motion was put and carried.

The meeting then separated, after passing by acclamation a vote of thanks to Dr. Forbes for his conduct in the chair.

EDITOR'S LETTER BOX.

THE JENNER MONUMENT.

LETTER FROM RICHARD TURNER, Esq., TO THE EDITOR.

SIR,—I fully concur in your remarks in the Journal of to-day respecting the Jenner Testimonial. We have heard too little of it; for a matter brought before us only once or twice, and at long intervals, is almost sure to be forgotten in the midst of our pressing professional and domestic duties.

The appeal of the committee should indeed come home with peculiar force to members of the medical profession; for, although the general public are the greater gainers, we can sympathise more fully with our departed brother (if, indeed, he should not be called a father in physic) the never-to-be-forgotten Jenner. But I do not remember seeing an appeal.

I suppose the statue is already almost paid for by the subscriptions, and this may be a very good and proper way of testifying the respect of the wide wide world for this good man; but I must acknowledge that if, while marking our sense of his value, we could carry forward his philanthropy by devoting a fund to some equally perpetual and more really useful purpose, I should with much more pleasure contribute, and expect others to do so likewise. I am not prepared to suggest any particular way of carrying out such an idea, but shall be glad by this letter to call the special attention of our Associates to the subject, and so to support your remarks at the latter part of the second paragraph of the leading article alluded to. I would propose the appropriating a small portion of vaccination fees to this object, and perhaps soliciting another small sum from the parents of the child vaccinated. This itself would, in the aggregate, furnish a goodly sum; and those who can afford it—and who cannot in some small measure?—might add to it at their pleasure.

Might not this fund be applied to establish an institution for the gratuitous vaccination of the poor, and the ready furnishing of lymph to medical practitioners by letter or application, the appointed vaccinator going, from time to time, to the original source for a new supply? I am, etc.,

RICHARD TURNER.

Tunbridge Wells, May 6th, 1853.

MR. FAGG'S REMARKS ON THE INCOME TAX.

LETTER FROM R. U. WEST, Esq., TO THE EDITOR.

SIR,—Your correspondent Mr. Fagg (a capital name, by the bye, for a country doctor) has put the case of the *working* income tax payers most admirably; but he has omitted one point, which his statement makes perfectly obvious. If his wealthy neighbour, Mr. Stockton, "grows vegetables of all kinds for the use of his family"—"fine crops of early peas and potatoes raised by his own labour"—"to say nothing of the pigs and poultry he breeds and rears for profit and use"; if, too, "he is tutor to his sons, and teaches his daughters music"—ought he not to pay income tax on more than the £510 he derives from the funds? Poor Richard says, "a penny saved is a penny got", and so it is. If Mr. Stockton saves by teaching his children, and by growing and raising his own vegetables, pigs, and poultry, he has more left to spend on other things. He has clearly *earned* the amount thus saved, and ought to pay the tax for it. I am, etc.

R. U. WEST.

Alford, Lincolnshire, May 7th, 1853.

CAUSTIC POTASH IN MALIGNANT DISEASE OF THE UTERUS.

LETTER FROM C. HOLMAN, M.D., TO THE EDITOR.

SIR,—In your number for May 6th, Dr. Oke makes such a sweeping condemnation of all patients affected with malignant uterine disease, that I must beg to be allowed to draw attention to the subject.

During my pupillage at Guy's, I saw several cases of hard cancer of the cervix, as well as one of fungous disease, successfully treated by the application of caustic potash. I have notes of the case of one patient in particular, the subject of carcinoma of the cervix, whom I saw some considerable time subsequent to the operation; she not only appeared well, but no trace of malignant disease or tendency to its return could be discovered in her.

The method of operating I have usually seen adopted, has been to include the part to be destroyed within the field of the speculum; to defend the healthy tissues by cotton-wool saturated with dilute acetic acid; and, after having thoroughly destroyed the diseased portion, to mop the part freely with the dilute acid. In some instances it may be advisable not to destroy the whole of the diseased portion at one sitting.

If taken in time, when the cervix is only affected, before the vagina, the body of the uterus, the inguinal or lumbar glands, have become the subject of the disease, I think it will be found that destruction of the diseased portion by potassa fusa or solid chloride of zinc, can be depended upon, as much as any of the operations for the removal of malignant disease from the other parts of the body.

I am, etc.,

C. HOLMAN, M.D.

Reigate, May 1853.

NEWS AND TOPICS OF THE DAY.

BILL [AS AMENDED ON RE-COMMITMENT] INTITULED "AN ACT FURTHER TO EXTEND AND MAKE COMPULSORY THE PRACTICE OF VACCINATION".

ARRANGEMENT OF CLAUSES.

Parishes or unions to be divided into districts for the purpose of vaccination, and places appointed for the performance of vaccination, sect. 1.

Children born after 1st August 1853, to be vaccinated within three or four months after birth, 2.

Certificate of successful vaccination to be delivered by medical officer, 3.

If the child be not in a fit state for vaccination, the medical officer to deliver a certificate to that effect, to be in force for two months, and to be renewed until vaccination be successfully performed, 4.

No fee to medical practitioner for duties under the act, 5.

Child's incapacity to receive the vaccine disease to be certified, 6.

A register of cases of successful vaccination to be kept, of which searches and extracts may be made, 7.

Notice to be given of the requirement of vaccination.

Penalty on parent or guardian failing to cause vaccination to be performed, 8.

Fee to registrar, 9.

Registrar-General to provide books and forms for carrying out the provisions of this act, 10.

Recovery of penalties, 11.

WHEREAS an act was passed in the fourth year of the reign of Her present Majesty, intituled "An Act to extend the Practice of Vaccination": And whereas an Act was passed in the fifth year of the same reign, intituled "An Act to amend an Act to extend the Practice of Vaccination": And whereas it is expedient that the practice of vaccination should be still further extended: Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords spiritual and temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. Within six weeks after the passing of this act, the guardians of every parish or union, and the overseers of every parish in which relief to the poor shall not be administered by guardians, in England and Wales, shall, subject to the approval of the Poor Law Board, divide such parish or union, if need be, into convenient districts, for the purpose of affording increased facilities for the vaccination of the poor; and shall appoint a convenient place in each such district, which shall in all practicable cases be not more than one mile from the furthest limit thereof, for the performance of such vaccination, and shall take the most effectual means for giving from time to time to all persons resident within such district due notice of the days and hours at which the medical officer or practitioner contracted with for such purpose will attend at such place to vaccinate all persons not already successfully vaccinated who may then appear there, and also of the days and hours at which such medical officer or practitioner will attend at such place to inspect the progress of such vaccination in the persons so vaccinated; and such guardians and overseers shall require such medical officer and practitioners in all practicable cases to perform such vaccination in the presence of the parent or other person by whom any

child may be brought to such place for such purpose from the arm of a healthy child there present; and where any such medical officer or practitioner shall not so perform vaccination as herein-before directed, he shall forthwith report the same, together with the reason thereof, to such guardians or overseers, who shall thereupon, if they shall not be satisfied with the reason so assigned, proceed, subject to the approval of the Poor Law Board, to take such measures as to them may seem fit for vacating the contract entered into with such medical officer or practitioner for the purpose of vaccination, or for enforcing the payment of any penalty provided for such case in such contract.

11. The father or mother of every child born in England or Wales after the first day of August in the year of our Lord one thousand eight hundred and fifty-three shall, within three calendar months after the birth of the said child, or in the event of the death, illness, absence, or inability of the father and mother, then the person who shall have the care, nurture, or custody of the said child, shall, within four calendar months after the birth of such child, take or cause to be taken the said child to the medical officer or practitioner appointed in the union or parish in which the said child is resident according to the provisions of the first-recited act, or to some other duly qualified medical practitioner, for the purpose of being vaccinated, and the said medical officer or practitioner so appointed, or such other duly qualified practitioner, shall and he is hereby required thereupon, or as soon after as it may conveniently and properly be done, to vaccinate the said child.

III. Upon and immediately after the successful vaccination of any child, the medical officer or practitioner who shall have performed the operation shall deliver to the father or mother of the said child, or to the person who shall have the care, nurture, or custody of the said child, a certificate under his hand, according to the form of schedule hereinafter inserted, marked (A.), that the said child has been successfully vaccinated, and shall also transmit a duplicate of the said certificate to the registrar of births and deaths of the sub-district in which the operation was performed; and such certificate shall, without further proof, be admissible as evidence of the successful vaccination of such child in any information or complaint which shall be brought against the father or mother of the said child, or against the person who shall have had the care, nurture, or custody of such child as aforesaid, for non-compliance with the provisions of this act.

IV. If such medical officer or practitioner be of opinion that any child which shall be brought to him for vaccination is not at the time when so brought for the purpose aforesaid in a fit and proper state to be successfully vaccinated, he shall postpone the vaccination until such time as he thinks the operation may be safely and successfully performed, and he shall, in the event of such postponement, thereupon and immediately deliver, without fee or reward, to the father or mother of such child, or the person having the care, nurture, or custody of the said child, a certificate under his hand according to the form of schedule hereinafter inserted, marked (B.), that the child is in an unfit state for successful vaccination, and such certificate shall remain in force for two calendar months from its delivery as aforesaid; and the father or mother of the said child, or the person having the care, nurture, or custody of the said child, shall, within two months next after the delivery of the said certificate as aforesaid, and if the said child be not vaccinated at or by the termination of such period of two months then during each succeeding period of two calendar months until such child has been successfully vaccinated, take or cause to be taken to the said medical officer or practitioner such child to be vaccinated by him; and if the said medical officer or practitioner deem the said child to be then in a fit and proper state for successful vaccination, he shall forthwith vaccinate it accordingly, and shall deliver to the father or mother of such child, or person having the care, nurture, or custody of such child, a certificate under his hand according to the form of schedule hereinafter inserted, marked (A.), that such child has been successfully vaccinated; but if the said medical officer or practitioner be of opinion that the child is still in an unfit state for successful vaccination, then he shall again deliver to the father or mother of such child, or person having the care, nurture, or custody of the said child, a certificate under his hand, according to the said form of schedule (B.), that the child is still in an unfit state for successful vaccination; and the said medical officer or practitioner, so long as such child remains in an unfit state for vaccination, and unvaccinated, shall at the expiration of every succeeding period of two calendar months deliver, if required, to the said father or mother of such child, or person having the

care, nurture, or custody of such child, a fresh certificate under his hand according to the said form of schedule; and the production of such certificate shall be a sufficient defence against any complaint which shall be brought against the said father or mother, or person having the care, nurture, or custody of such child, for noncompliance with the provisions of this act.

v. No medical officer or practitioner appointed as aforesaid shall be entitled to any fee or remuneration for the duties imposed upon him by this act other than is provided for by the said first-recited act.

vi. In the event of any medical practitioner acting under the provisions of this act being of opinion that any child that has been taken to him for the purpose of being vaccinated as hereinbefore provided is insusceptible of the vaccine disease, he shall deliver to the father or mother, or person having the care, nurture, or custody of such child, a certificate under his hand according to the form of schedule hereinafter inserted marked (D.); and the production of such certificate shall be a sufficient defence against any complaint which may be brought against the said father, mother, or person having the care, nurture, or custody of such child for noncompliance with the provisions of this act.

vii. The registrar of births and deaths in every subdistrict in which the operation has been performed shall keep a register of the persons of whose successful vaccination a certificate shall have been transmitted to him as above provided by the said medical officer or practitioner, and shall at all reasonable times allow searches to be made of any such register book in his keeping, and shall give a copy, certified under his hand, of any entry or entries in the same, on payment of the fee hereinafter mentioned; (that is to say,) for every search extending over a period of not more than six months, one shilling, and one shilling and sixpence for every additional year, and the sum of sixpence for every single certificate.

viii. The registrar of births and deaths in every subdistrict shall, on or within seven days after the registration of the birth of any child not already vaccinated within the said subdistrict, give notice in writing in manner hereinafter directed, and according to the form of schedule hereinafter inserted, marked (c.), to the father or mother of such child, or in the event of the death, illness, absence, or inability from sickness or otherwise of the father and mother, then to the person upon whom the care, nurture, or custody of such child shall have devolved, that it is the duty of such father or mother, or person having the care, nurture, or custody of such child as aforesaid, to take care that the said child shall be vaccinated in the manner directed by this act; and the registrar shall deliver such notice at the time of or within seven days after the registration of such birth to the father or mother of such child, or to such other person as aforesaid upon whom the care, nurture, or custody of such child shall have devolved, and shall together therewith deliver to such person a notice of the days, hours, and places within the district of such registrar at which the medical officer or practitioner as hereinbefore provided will attend for the purpose of vaccination; and if after such notice the father or mother of the said child, or the person so having as aforesaid the care, nurture, or custody of the said child, shall not accordingly cause such child to be vaccinated, then such father or mother, or person having the care, nurture, or custody of such child as aforesaid, so offending, shall forfeit a sum not exceeding one pound upon the first complaint, to be afterwards increased at the discretion of the justices imposing the penalty as hereinafter provided, in case of repeated complaints for non-compliance with the provisions of this act in respect of the said child; provided that the whole amount of such penalty shall not exceed five pounds.

ix. A fee of threepence shall be paid to such registrar for each child vaccinated in respect of which he shall have performed the duties required in this act; and he shall keep a book, to be provided as hereinafter directed, containing a minute of his having duly given such notice as hereinbefore directed; and the said fee shall be payable in the same manner as the fee now payable to such registrar for registering the birth of such child as aforesaid is paid.

x. The registrar general for England and Wales shall, and he is empowered and directed, within two months after the passing of this act, to frame and provide such books, forms, and regulations as he may deem requisite for carrying into full effect the provisions of this act, and shall transmit the same to the superintendent registrars of each district in England and Wales, who shall deliver to the medical officers so appointed as aforesaid, and other duly qualified medical practitioners in the said district, such of the said books, forms, and regulations, as they

may require for the performance of the duties imposed upon them by this act; and the expenses to be incurred by the Registrar-General under the provisions of this act, shall be defrayed in the same manner as the expenses under the act of the sixth and seventh years of William the Fourth, chapter eighty-five.

xi. All penalties by this act imposed, shall be recovered before any two justices of the peace for the county, city, or place where the offence shall have happened, upon the information or complaint of any person; and if on the conviction of the offender such penalties, with the costs of conviction, shall not forthwith be paid, the same shall be levied by distress and sale of the goods and chattels of the offender, by warrant under the hand and seal of such justices.

Schedules referred to by this Act.

SCHEDULE (A).

I, the undersigned, hereby certify, that _____, the child of _____, aged _____, of the parish of _____, in the county of _____, has been successfully vaccinated by me.
Dated this _____ day of _____, 185 .

(Signed) A.B.,

Surgeon of the Union or Parish (or other Medical Practitioner, as the case may be).

SCHEDULE (B).

I, the undersigned, hereby certify that I am of opinion that _____, the child of _____, of the parish of _____, in the county of _____, aged _____, is not now in a fit and proper state to be successfully vaccinated, and I do hereby postpone the vaccination until the _____ day of _____.
Dated this _____ day of _____, 185 .

(Signed) A.B.,

Surgeon of the Union or Parish (or other Medical Practitioner, as the case may be).

SCHEDULE (C).

I, the undersigned, hereby give you notice, and require you to have C.D. vaccinated within three (or four, as the case may be, according to the Second Section of this Act) months after the birth, pursuant to the Provisions and Directions of the Act of the 16 Victoria, cap. _____. As witness my hand this day of _____, 185 .

J.B.,

Registrar of Births and Deaths for the _____ sub-district (as the case may be).

SCHEDULE (D).

I, the undersigned, hereby certify that I am of opinion that _____, the child of _____, of the parish of _____, in the county of _____, is insusceptible of the vaccine disease.
Dated this _____ day of _____, 185 .

(Signed) A.B.,

Surgeon of the Union or Parish of _____ (or other Medical Practitioner, as the case may be).

NORFOLK AND NORWICH HOSPITAL.

The Anniversary Meeting of the Governors of the Norfolk and Norwich Hospital was held on Saturday, April 9th, at the hospital, Sir THOMAS B. B. BEEVOR, Bart., in the Chair. The attendance of governors was numerous.

QUARTERLY REPORT.

"The Board of Management beg to present to the governors their quarterly report. The internal condition of the hospital, and the conduct of the officers and servants, continue to give satisfaction. The usual quarterly inspection of the building and premises has been made by a committee of the board, and every part appears to be in good and efficient repair. The following donations have been received by the treasurer, and are thankfully acknowledged: Charles Lombe, Esq., £100; Lord Henniker, fully acknowledged: Charles Lombe, Esq., £22:9:0. £10; Col. Oakes, £10; Grand Jury of Lent Assizes, £22:9:0. A legacy of £19 has been bequeathed to the hospital by Mrs. Archer, late of Coltishall. The poor boxes have been opened, and the sum of 5s. found therein, which has been paid over to the treasurer."

Mr. E. HOWES, Chairman of the Board of Management, moved the adoption of the report. Mr. MARSHAM seconded the motion, which was carried *nem. con.*

ANNUAL REPORT.*

"The Board of Management present to the governors their

* We have omitted a few sentences of no general interest.

Fifth Annual Report, together with the financial statement for the year 1852.

"The attendance of the members of the board of management during the year has averaged something over eleven weekly; the plan of house visiting still continues to be most useful, and the reports of the visitors on the internal state of the house most satisfactory.

"In addition to the usual statement of the number of patients discharged during the past year, the medical staff have prepared a statistical table of diseases and results during the year 1852, which will be regularly continued.

"A microscope has been obtained for the hospital, for which £35 was contributed from the hospital funds, and £32, the rest of its cost, by anonymous donors.

"The receipts during the year 1852 amounted to £4338:5:0, which included the following items:—Balance in the hands of the treasurer at the end of the year 1851, £1064:16:2; annual subscriptions, £1600; benefactions, £117; dividends on stock, £647:17:5; and legacies, £769:10:0. The disbursements amounted to £3301:11:2, including the following items:—Expenses of housekeeping, £1656:8:10; salaries and wages, £594:16:0; expenses of dispensing, £259:8:5; repairs, £186:19:9; linen and furniture, £76:4:4; incidental expenses, £127:13:10; and purchase of £406:12:2, 3 per cent. consols, £400; leaving a balance of £1036:14:7.

"1275 patients (including 596 in-patients and 679 out) had been admitted during the year by recommendations, and 443 (including 149 in, and 294 out) as casualties; 477 patients remained on the books at the end of the last year, which made a total of 2195 persons who had received relief from the hospital from December 31, 1851, to December 31, 1852. Of these, 711 had been cured, 294 had been relieved, 28 had been discharged as not likely to receive any benefit, and only 8 as incurable. The daily average number of patients in the house had been 112, and the average number of days each in-patient had remained on the books was 48½ days. 680 patients at present remained on the books, of whom 97 were in-patients, and 583 out-patients. 77,519 patients (including 43,967 in, and 33,552 out) had been relieved by the hospital since the opening in the year 1772."

The report was adopted unanimously, on the motion of the Rev. E. POSTLE, seconded by Mr. W. C. HOTSON.

EXCLUSION OF THE MEDICAL STAFF FROM THE MEETINGS OF THE BOARD OF MANAGEMENT.

The CHAIRMAN read the following communication from the medical officers.

"TO THE GOVERNORS OF THE NORFOLK AND NORWICH HOSPITAL.

"We, the undersigned, medical and surgical officers of the hospital, solicit the attention of the governors to our position with respect to the board of management. According to the hospital rules, as altered in 1848, the honorary medical officers are precluded from taking any part in the proceedings of the board of management; and we believe such exclusion to be injurious to the interests of the institution, by preventing that free and beneficial cooperation between the managing bodies of the hospital, which existed without interruption for more than seventy years.

"W. H. RANKING, M.D. "ARCHIBALD DALRYMPLE, Surgeon.
"E. COPEMAN, M.D. "W. P. NICHOLS, Surgeon.

"B. H. NORGATE, Surgeon. "G. W. W. FIRTH, Assist. Surgeon.

Norfolk and Norwich Hospital, March, 31st, 1853."

Dr. COPEMAN believed that it was very desirable that the medical officers should be allowed to take part in the conversations and discussions at the board, and had no doubt that their presence would often facilitate business and obviate unfavourable impressions. In proof of a similar feeling having been entertained by the board, he would read the following resolutions, passed on the 16th of August, 1851: "Resolved, that the chairman be requested to invite the medical staff more frequently to avail themselves of their privileges as governors of attending the weekly meeting of the board." The chairman on that occasion addressed a very courteous letter to the medical staff; and he (Dr. Copeman) alluded to the circumstance to show that something was then felt to be wanting at the board which could be supplied only by the attendance of the medical officers. They would ask, perhaps, why, after such an invitation, did not the medical officers attend? The answer sent by the medical staff would partly explain the reason, and at the same time would show that the medical officers were anxious to cooperate with the board for the benefit of the institution.

"The undersigned medical and surgical officers of the Norfolk and Norwich Hospital have the honour to thank the chairman

of the Board of Management for the courtesy of his letter of the 16th inst. They beg leave to state in reply, that they have hitherto felt themselves precluded by rule 15, from any useful attendance upon the meetings of the board over which he presides, since they would have been subject to the same consequences of its infringement as those which occurred to their late eminent colleague, Mr. Crosse; and they hesitate still to avail themselves of their privilege while that rule remains unmodified. They beg to assure the gentlemen of the board that they entirely appreciate the motives which dictated their nomination on this subject, and that they anxiously desire increased opportunities of cooperation with the board of management, sincerely believing that the interests and harmony of the hospital will be thereby much promoted.

(Signed) "R. HULL, W. H. RANKING, E. COPEMAN,
"B. H. NORGATE, G. W. W. FIRTH."

The allusion to the late Mr. Crosse referred to a transaction which took place at the board on March 10th, 1849. There was some demur about a bill for instruments; Mr. Crosse, who was concerned in the matter, offered an explanation, but was refused a hearing; and although he was the only person who could explain the matter, he was compelled to make his communication through a member of the board. On a more recent occasion, a member of the board objected to hear a communication from one of the medical officers, on the ground that he had no right to volunteer a statement, or take part in the proceedings. He (Dr. Copeman) did not bring these cases forward with a view of casting any reflection upon those who objected; on the contrary, he thought that they acted entirely in accordance with the rules of the hospital; but he mentioned them to convince the meeting that the medical officers had grounds for declining the invitation of the board, and that by their legal exclusion they were placed in a false position—a position uncomfortable to themselves, and injurious, he did not hesitate to say, to the institution itself. The medical staff had hoped that the board of management, after receiving their answer, would have carried on the work they had begun, and taken steps to remove the difficulty which prevented the medical officers from accepting the invitation of the board; but no further notice of the matter had been taken by them, and the obstruction remained. This was the first year that they had had a published tabular statement of diseases, accidents, and operations, or that scientific record of such matters had been kept in the hospital. As a medical man, he (Dr. Copeman) was aware of the deficiency, and had proposed that such documents should be established. He was at that time a member of the board, with perfect liberty to make any proposition he pleased. Now, however, that he was one of the medical staff, and in a better position to understand matters connected with the hospital, he found himself trammelled by an exclusive law, and deprived of the right to enter into any discussion at the board.

He would now direct their attention to the practice pursued in other hospitals in such matters. He would begin with the sole precedent for the rule observed in this establishment:—In the Nottingham Hospital the medical officers were not members of the board, *ex officio* or otherwise; at Bath, the senior physician and surgeon were elected members, the other members of the staff having the privilege of attending the meetings, but having no votes; at Liverpool, there was a separate medical board; at Birmingham, there were six honorary medical officers, two of whom were appointed to the board of management by the Queen's College, and there was no law to prevent the whole of them being on the committee of council; at Gloucester, they were eligible for election, and were allowed to attend and give their opinion, but not to vote unless elected; at Bristol, Berkshire, Stafford, Salop, and Canterbury, there was no law to prevent their being elected; at Leeds and Bedford, the honorary medical officers had the same privileges as other governors; at Chester, Derby, Worcester, Oxford, Manchester, Newcastle, Lincoln, Sussex, Bury, Ipswich, Northampton, Cambridge, Hull, and Sheffield, the medical officers were members *ex officio*; at the York and Colchester hospitals, it was not stated whether they were eligible or not. Thus, then, in other provincial hospitals the medical officers were, in a great majority, *ex officio* members of the board of management; in most others they were eligible for election; and in scarcely any were they excluded altogether. (Hear, hear.)

He would now refer to the practice of their own hospital from its commencement to the year 1848. For a period of more than seventy years the medical officers were more or less concerned in the business of almost every board, and formed part of almost every committee. No alteration of importance, no transaction of

consequence took place without the assistance of one or more of the medical officers; and, lest it should be said that this mutual co-operation was found objectionable, he would quote a resolution, passed unanimously at a general board of 104 guardians, which proved it to have been highly beneficial: "October 10th, 1827. Moved by Rev. J. D. Borton, and unanimously carried, That the thanks of the board be given to the medical officers for their constant and unvarying attention to the interests of the Norfolk and Norwich Hospital; for their readiness to communicate information upon all subjects laid before them, involving either the management or the credit of this highly valuable institution." On the ground, therefore, of the desire expressed by the board that the medical officers should be more frequently present at their meetings; the willingness of the medical staff to assist in the proceedings of the board; of the very general practice of other provincial hospitals; and of their own for more than seventy years; on these grounds, and for the sake of the advantages which he conscientiously believed would result from its adoption, he begged to move the following resolution:

"That the following addition be made to rule 15: Except the honorary medical and surgical officers, who shall be honorary members of the board of management, with liberty to take part in the proceedings, but not to vote upon any question before the board."

Mr. WEBSTER thought that it was not dignified for the profession to which he belonged, to depart from the practice pursued in all unions, where it was an established rule that no interested parties should have any power in the management of the institution with which they were officially connected. It might be said that, though they might be allowed to take part in the proceedings of the board, yet that they could not vote; but he knew that it was easy for them to whisper, and he had been there frequently enough to see that there were on that board friends of the medical officers, or otherwise he could not conceive how certain matters had occurred there with regard to himself. He had found some relative or friend of one of the staff make observations at that board which were as uncalled for as they were uncourteous. Having been in the profession some thirty-seven years, he might perhaps have been competent to have formed an opinion on many matters relating to the hospital; and he declared that he had never entered it except with the spirit and intention of being useful. He admitted that if the medical officers were allowed to take part in the proceedings, they might be able to explain a great many matters to the board; but at the same time they would also be able to make explanations as to other matters, when parties who were implicated would not have the opportunity of removing impressions which had been created. He was decidedly opposed to the medical gentlemen taking any part in the proceedings of the board, except when solicited; and as they could, by the present regulations, always be present, he confessed he did not see the drift of this motion, unless there were something attached to it which did not appear in the naked proposition.

The Rev. E. POSTLE said that, with reference to the resolution of the board in 1851, inviting the medical men to exercise oftener their privilege of attending the meetings, Mr. Howes, who was then the chairman, would probably explain whether these gentlemen were invited merely to show themselves at the board, without taking any part in its proceedings.

Mr. E. HOWES said that the communication alluded to was addressed to the medical staff with the view, principally, that by attending at the board they should be a little more conversant with the reasons on which the board acted on several occasions, and also in order that the board might put to them inquiries which might be much better answered *vis à voce* than by letter.

The Rev. E. POSTLE said that he thought, then, that the medical officers had quite sufficient privilege already.

The Rev. J. HOLMES had the greatest respect for the medical staff of that establishment, and he thought that few men deserved greater regard for their professional ability and their private character. He could not help thinking, however, that there was a place for the persons who had to manage, and there was another place for the persons who were to be supervised; and he thought, also, that there was a marked distinction between medical officers of that establishment, and medical gentlemen in their private character. When they accepted office in the institution, they rendered themselves liable to the same control, supervision, and fault-finding, as any other officers in the establishment. The intention of the rules laid down for the well-working of the establishment was to provide a controlling power. The great controlling power was the meeting now assembled; subordinate to it was that of the board of management. Having sat on that board for four years, he could

say that its members felt it their duty to supervise everything connected with the establishment, and, where fault was to be found, to find it, it mattered not how high might be the character or position of the person. He (Mr. Holmes) did not pretend to say that the board of management should say, "You shall do this or that"; or, "You shall not do this"; but he insisted that it was their duty, if they anticipated anything improper, to say, "If you do so and so, we shall interfere; we shall represent your conduct to the governors, and obtain your dismissal". Now, he put it on this broad ground, whether it was right that the medical officers, whose conduct, he unhesitatingly affirmed, might be called in question before that board, should be allowed to sit there, and have their conduct canvassed, and take part in the discussion on it. The laws of the hospital at present gave them power to attend. The present motion only asked for power to take part in the debates; yet, hereafter, they would ask also for the power of voting. He thought that the medical officers were trying to place themselves in a very improper position, as, if they were granted the privilege which they sought to obtain, they would be frequently obliged to hear very unpleasant remarks, or else to "cut" the room. This was no hypothetical case. One of the medical officers very lately, by a visitation of Providence, completely lost his memory, but, not being aware of his infirmity, continued to prescribe for the patients, and if they had not had a careful and skilful house-surgeon, serious consequences might have resulted. The board determined accordingly to make a representation to this gentleman, and request him to resign, which, after a great deal of reluctance, he consented to do. The governors would understand, therefore, that there were cases in which the board felt they were justified in interfering with their medical officers; and it was not merely a mental infirmity that might give rise to a similar circumstance hereafter; but there were many circumstances, which the meeting might easily comprehend, which might compel the board to act in the same manner again. This, then, was the relative position of the board of management, and their medical staff—the board as the controlling power, and the medical officers as a highly respectable body of men, but, nevertheless, persons who must, like other men, be controlled and supervised. He was confident that, if ever the medical staff should succeed in obtaining a dominant position in that board, the institution would certainly be ruined—not that the medical gentlemen were not highly honourable, but because it was, as he believed, essential for the well-being of the hospital that its affairs should be managed by an independent body. He had observed in the long experience he had had at the board, that there was too much of an *esprit du corps* among medical men, which rendered them unfit to be either the prevailing or dominant influence there. There was quite enough of the medical element in the board.

Mr. D. DALRYMPLE said that Mr. Holmes had given several unanswerable reasons why medical men should be entitled to take part in the proceedings at medical boards. If the medical staff were allowed to be present at the board, what practical benefit was there in restricting them from taking part in the proceedings? The board had always, in revising the two-monthly list, to ascertain from the medical officers the state of health of certain patients, the benefit they had derived, and the period it was anticipated they would have to remain in the hospital, and this would be much better ascertained were the medical officers present at the board, than by the present stereotype communications. Mr. Holmes had not shown one reason why the power of the governing body of the hospital would not be exercised with as much efficiency if every one of the medical staff had the privilege of sitting at the board, and taking part in the proceedings; nor did he think that any one could be prevented, by the presence of the staff, from animadverting on the conduct of that body, since nothing, he thought, would be more likely to lead to a proper investigation of any complaint than the presence of the parties implicated. As belonging to that profession, he (Mr. Dalrymple) believed that they should like everything to be open, and that the proposition made by Dr. Copeman would promote a better feeling, and a closer intercourse between the medical staff and the board of management. Those who opposed the measure should show good cause why a rule which had worked well for so lengthened a period, should ever have been altered so as to exclude the medical officers from taking part in the proceedings of the board. As to the equality in position of the medical staff and the governors, both could attend the meetings of the board of management, and watch their proceedings, but the governor could be elected on the board to which the medical officer was not eligible. He was not, therefore, on the same footing with other governors. They thus de-

prive themselves of the assistance of those very persons who, by their daily and hourly intercourse with the patients of this hospital, and the management of it, were best calculated to bring the knowledge which was most wanted. When they reviewed the list of the members of the board of management, and observed that the greater part of them were entirely unacquainted with the routine business of the establishment, or with those little *minutiae* the attention to which was of such importance in that institution, they would readily appreciate the advantage of having at least a portion of the medical staff to assist in the administration of affairs. They were bound to place in their proper position a body of gentlemen who devoted to the benefit of the hospital their time, their services, and their money; for it was, he assured them, no small diminution from their professional incomes.

The Rev. Mr. HOLMES said that the medical officers acquired position and character from their connexion with the hospital.

Mr. TUCK felt most strongly that the proposition of Dr. Copeman would confer great benefit upon the institution.

Mr. UTEN BROWNE had not heard, either from the gentleman who moved the resolution, or from those who supported it, a single good reason in its favour. The governors of this hospital, until the alteration took place by which the board of management was elected, were all competent to take part in the administration of the affairs of the hospital. The medical men, as governors, under the old constitution, exercised the same right; but by the alteration in the constitution, the governors had been deprived of that right. They might, it was true, enter that room, and observe the proceedings of the board of management, but if they ventured to make any observation, they should—no doubt with great politeness—be told, like the medical men, to “hold their tongues”. Now, he did not think that that of which no governor complained, should be complained of by the medical men. It might be said that the governor was eligible, but that the medical man was not. The medical men, however, enjoyed, in common with the other governors, the right of electing the board; and it was quite clear, therefore, that the medical staff had it in their power, by making legitimate use of that power, to elect a board of management, of whom the majority should be composed of persons whom they considered to be best calculated to promote the interests of the institution.

Let them only conceive the state of things which would arise if this proposition were carried. Suppose a question came before the board affecting in any way the conduct of a member of the medical staff. The medical members of the board could muster in force, and though he was very far indeed from imputing to any one of those gentlemen a desire to take any particular course in order to shield any of their number, yet they knew that the *esprit de corps* was particularly strong among these gentlemen, and that they always took a favourable view of any matter which affected themselves, or those with whom they were in the habit of intercourse, and with whom, as in this case, they had a bond of brotherhood; and, therefore, he thought that the medical staff would come to the board impressed—and honestly impressed—with the conviction that whatever might be said, the person who said it was wrong; that whatever charge might be made, it was utterly unfounded, and they would raise a discussion upon the point, and though it was perfectly true that they would not have the right of voting, yet they would have the right of speaking, and they would speak at a considerable length too—(laughter)—and it was very likely that they would, by the influence, and the proper influence, which they possessed, be successful in inducing the board either to pass over the complaint altogether, or to say, without assigning any reason, that they were satisfied with the conduct of the officer who had been implicated. Now, that was the state of things which he thought would be very likely to exist if these gentlemen became *ex officio* members of the board of management.

Dr. RANKING did not rise to speak in support of Dr. Copeman's motion, because he thought it more in accordance with the position of the medical staff that their case should be taken up by others than themselves; but he wished, in reply to Mr. Browne's statement that he could not conceive any case in which benefit could arise to the hospital from the presence of the medical officers at the board of management, to assure them that such cases did frequently occur, and that a vast number of questions of a purely medical and surgical nature, which could only be answered by medical men, were frequently required to be published by the board. That he considered a sufficient ground and necessity for the presence of the medical staff. And he certainly thought that the medical man should not be placed in the same position as the porter or nurse of the establishment, to be sent for by the board when wanted.

The Hon. and Rev. Lord BAYNING made the suggestion with an earnest desire of promoting the best feelings between the medical gentlemen and the board, whether one physician and one surgeon should have seats at the board. To a proposition of that sort, he should lend a ready consideration; but his objections to the whole medical staff taking part in the proceedings of the board were not removed.

Mr. J. G. JOHNSON said, that having been formerly one of the medical officers for nearly twenty years, he might be allowed to make a few remarks, without laying himself open to the imputation of having any personal interest in the question under discussion. It had been very properly put by those opposed to Dr. Copeman's proposition; first, whether any inconvenience had been felt, and secondly, what would be the inconveniences felt by the proposed change, and which of the two inconveniences would be greater. Now, with respect to the inconvenience which had been experienced under the present system, two instances were alleged in which medical officers had been impeded in taking what he considered to be a proper part at a meeting of the board of management, and he was quite sure that no gentleman belonging to his profession, would ever, after such treatment give the board an opportunity of occasioning a third instance. The present system was a general inconvenience; and the rule which prevented the medical staff from attending at the board in the position which they had a right to occupy, should, therefore, be altered. He did not hesitate to say that his principal reason for retiring from that board, was because he saw steps taken with relation to the conduct of some of his medical brethren, and without their knowledge, which, had he been at the time on the staff, would have been exceedingly disagreeable and repugnant to his feelings. According to the present rules, a medical officer had no opportunity of making any explanation on matters which none but medical men could understand, unless he attended before the board, at the summons of their chairman, like the porter, or the nurse of the establishment, and his explanation might, even then, be objected to by any members of the board. Now, that did happen to one of the most talented officers of the institution, Mr. Crosse, and had also happened since in the case of Mr. Firth, and he must tell them that such treatment was most repugnant to the feelings of the medical gentlemen connected with the hospital. He concurred with the suggestion made by Lord Bayning, but would propose that instead of a physician and a surgeon being elected for a certain period, the medical and surgical officers of the week preceding should be *ex officio* members of the board of management. Mr. Browne had observed that when the constitution of the institution was altered, the governors were excluded from the board. The conduct of the governors, however, did not come under the consideration of the board of management, whereas the conduct of the medical and surgical officers must and should and always would continue to be brought under their notice. To take a very ordinary instance—a complaint was made by a patient, and the patient and nurse were called and made their statements to the board, but there was no medical officer there to hear it, and consequently no explanation. An impression, very often unfavourable and unjust to the officer, was thus formed by the board, which the slightest explanation would have removed. Mischief of an extensive character arose in this manner, and would always continue to arise until some alteration was made in the rule. He would move, therefore, “That the medical and the surgical officer of the preceding week, or the assistant surgeon if they be absent, be *ex officio* members of the board of management.”

Lord BAYNING seconded the amendment.

The Rev. Mr. HOLMES considered the amendment so important, and so entirely different from the motion of which Dr. Copeman had given notice, that it was impossible for them to make up their minds upon it suddenly. He hoped, therefore, that the discussion would be adjourned.

Mr. TUCK apprehended that they had not the power to entertain the amendment, because the 10th rule provided—“That no motion, which has for its object the repeal or alteration of any existing law, or making any new law, shall be entertained, unless notice shall have been given at the previous quarterly board.” The motion of which Dr. Copeman had given notice referred to rule 15, while Mr. Johnson's amendment related to rule 14.

The Rev. A. W. KEPPEL moved, and Mr. D. DALRYMPLE seconded, the adjournment of the discussion.

Dr. COPEMAN having withdrawn his motion in favour of Mr. Johnson's amendment, the discussion was adjourned to the next quarterly board.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XX.

LONDON: FRIDAY EVENING, MAY 20, 1853.

NEW SERIES.

HOSPITAL ABUSES, ADVICE GRATIS, AND MEDICAL BENEVOLENCE.

LETTERS have, for months past, poured in upon us in rich abundance, denouncing the mischievous tendencies, and deploping the evil consequences, of our hospital system, and of the equally injurious and meaner system of giving "advice gratis" of a morning, as a bait for popularity and practice. There is a profusion of compliments bestowed upon our humble efforts to awaken the profession to emancipate itself from the evils which these systems inflict upon it; but very few indeed of our applauding allies allow us to authenticate their disclosures with their names. This timidity on the part of hospital reformers, we cannot help thinking, is culpable, and scarcely to have been looked for in those honourable men by whom it is manifested. It is impossible, however, not to feel some degree of sympathy with many excellent colleagues, who, in the present state of professional and public apathy, shrink from hazarding their all in a warfare which they know cannot be conducted successfully by small parties of skirmishers, and which demands, as the only hope of victory, a numerous, resolute, and well-disciplined army. It is a pity, however, that those who, in private letters and conversations, admit, with us, that a tide of social and professional degeneration is, under the guise of charity, flowing over the kingdom with rapid though stealthy wave, should feel so much hesitation or so little power to stem the current; and that they should think they have contended manfully for the cause, by addressing to us "private" communications, or, in some quiet coterie, applauding the boldness and the honesty of those who do not shrink from bearing the burden of the opening battle between real and spurious medical philanthropy. These reflections arose as we perused a letter marked "private", which we received a few days ago, and from which, as it is a fair sample of many which have been addressed to us, we quote a paragraph, omitting names and allusions which might lead to the identification of the writer.

"Do show up the public abuses and medical intrigues which are now going on at Blaque Hospital. If you will promise not to name me as your informant, I will give you the very fullest particulars of the mischief which that institution works upon us under the names of charity and benevolence. I will give you some pretty little histories. The whole system ought to be exposed,—root and branch it is corrupt; and most of the medical men in the town and neighbourhood are of opinion that, under the present management, the hospital is a great public evil, as it diverts practice from many deserving general practitioners who are struggling to support their families, and generates a devil-me-care spirit of improvidence among the artisans and petty tradesmen. The hospital and the lying-in society, I am certain, check every prompting to lay aside, from the weekly earnings, a reserve fund for sickness; and the money which would go to the doctor, were there no indiscriminate hospital aid in this place, goes to the publican and the betting-office. The most disgusting part of the affair is this, that our gentry and hospital-staff are not satisfied with demoralizing the people, and defrauding the medical profession, but they

must have their names boastfully published in reports and newspapers as charitable donors! Now some of these persons subscribe to the hospital chiefly that they may send their sick servants to it, and thus avoid a medical man's account for attendance on them. As I am not attached to the hospital, I am obliged, every morning, to give 'advice gratis' to all who come in shabby attire, or in the dress of working-men. If I did not do this, the parties would go to the hospital, and Dr. —, in place of me, would have his skill and kindness advertised."

While we feel discouraged by the evidence which such letters afford of the timidity and thralldom engendered by the present hospital system, we are not inclined to despair. Reforms, which no man is strong enough to achieve single-handed, may be accomplished by a league. If every town had its hospital-reform committee, and if there were a central conference formed of delegates from these committees, the nature and extent of these universally-deplored abuses could be ascertained, and placed in an authentic shape before the public; and hospitals might even, in our day, become sources of good, and not of evil. We have here broached the idea of a Hospital Reform Society, because we have been assured by many that such an institution only requires to be founded, to be sure of great support. Undoubtedly, if such a society could be established, and conducted on the broadest principles of charity, conciliation, and justice, its efforts would not long be without their reward.

The letter of "Observator", at p. 447, is calculated to carry conviction to the minds of many, but especially to those unlucky though often accomplished men, who, year after year, are stranded in their pursuit of the emoluments of metropolitan practice, after having spent health, mental serenity, and fortune, in a vain and desperate struggle of many years duration. In London, the amount of fees which are unjustly filched from the profession by the hospital system, is enormous. A rich farmer from Somersetshire, some years ago, entered a London hospital for the purpose of having a necessary operation performed. On his return to the country, he boasted of having had "the best advice" for nothing; and, by his suggestion, several rural friends, able to pay for advice, became both out-patients and in-patients of the same institution. A few years before the death of the late Sir Astley Cooper, a general practitioner (our informant) made an arrangement with that eminent surgeon to operate upon a patient who had stone in the bladder. The stipulated fee was eighty guineas. When Sir Astley entered the room, an immediate look of recognition passed between him and the patient, who, it turned out, had long been in the habit of attending as an out-patient at Guy's. This person lived comfortably, and left to his heirs upwards of £40,000. Nothing could be easier than to multiply anecdotes of this kind; but as no one denies that hospitals are often made the means of depriving the profession of its legitimate rewards, and of ministering to the mean avarice of many, we are unwilling to occupy more space by giving additional illustrations. We cannot, however, leave this topic without laying before our readers an

advertisement which, a few days ago, we cut from the *Times* newspaper,—as we think it ought emphatically to proclaim the necessity of no time being lost in reforming hospital abuses, and placing “advice gratis” within the confines of benevolence. The following is an exact reprint of the advertisement to which we have referred :—

“UNIVERSITY COLLEGE HOSPITAL.—A patient, who has been cured by surgical treatment, at University College Hospital, offers £50 towards a sum of £60,000, for the purpose of endowing that hospital with eighty more surgical beds, in perpetuity; and proposes, as essential conditions with the same, that such beds shall be free to deserving patients, and that the medical officers of the hospital shall subject themselves to re-election every five years for the future. If the proposal is approved, he will subscribe the first £50 of each £10,000.”

The rapid multiplication of hospitals for the treatment of special diseases, to which Mr. Arrowsmith alludes at the close of his letter (p. 447), is too extensive a subject for us to enter upon at present. We must, however, commend his letter to the favourable attention of our readers. Mr. Smith's communication, at p. 446, has also within it the germs of useful suggestions; and his long and disinterested labours in the cause of medical philanthropy, as opposed to indiscriminate medical relief, commend his views to the respectful consideration of his brethren. Our duty is to lay such documents before the members of the profession, and to urge them to unite, for the purpose of devising and carrying out the necessary reforms. There may be a practical difficulty in carrying out any universally applicable scheme of amendment; but there are several objects which a united profession might accomplish, and which, if accomplished, could not fail to be productive of great and immediate benefits. We may mention three important objects, which are undoubtedly attainable by means of cooperation and energy on the part of medical practitioners :—

FIRST: An active share being taken in the management of medical charities, by the whole body of the medical practitioners residing within the towns or districts within which these charities are situated.

SECOND: The fearless exposure of those persons who subscribe to hospitals and dispensaries as a cheap means of procuring medicine and medical attendance for their servants.

THIRD: The enlightenment of the sincerely Christian and charitable public in methods of giving their bounty with discrimination; and the impressing upon them the necessity of making their gifts conditional upon a machinery being provided by hospital committees, such as is adequate to ensure the judicious application of the money with which they are entrusted.

If the first object be well carried out, the other two are likely also to be secured. In support of this view, we may mention that, through the influence of the medical element in the executive board of St. Mary's Hospital, an efficient system of registration of the out-patients has been prominently brought forward in the report for the year 1852, which is now before us. The fulfilment of such a measure must prove a corner-stone of hospital reform. Careful registration would make it impossible for sixty cases to be entered and prescribed for in an hour, as is actually stated of some hospitals, in the reports of which the number of cases prescribed for is the leading argument in favour of public liberality. Medicine would thus be relieved from the dis-

credit which it now endures, through much of the advice given at our hospitals being worse than useless, from the reckless haste with which it is administered.

THE PROSPECTS OF MEDICAL REFORM.

It is with sincere pleasure that we announce that in all parts of the kingdom an active movement has commenced in favour of the Medical Reform Bill of the Association. Petitions have already been sent up from many towns, and many more, we understand, are in course of signature. At a meeting of medical practitioners held in London, on Wednesday last, a Committee was formed, “for the purpose of obtaining an act of Parliament during the present session of Parliament, for the better regulation of the medical profession”. Dr. LANKESTER is chairman, and Dr. D. JONES and Mr. W. M. POWELL secretaries, of this Committee. At the meeting referred to, the principles of the Medical Bill of the Association were fully considered and unanimously approved. As this Committee has power to add to its members, and proposes to meet weekly for the furtherance of its objects, we earnestly recommend to all legally qualified medical practitioners to co-operate with Dr. Lankester and his colleagues. We anticipate that an immense impetus will be given to the medical reform question by this combination of metropolitan reformers, which is admirably organized, and full of zeal. Our advertising columns contain the official announcement of the formation of this Committee. Next week we hope to be able to communicate additional particulars.

We are glad to find, amongst other indications of the state of feeling on this subject, that the *Daily News* is again devoting its columns to the advocacy of the immediate settlement of the great question of medical reform. We have often lamented the popular apathy on this subject, which, combined with the differences of medical men, has so long delayed any just or comprehensive settlement of this question. In an article commenting on the deputation, which on Thursday, the 12th inst., waited on Lord ABERDEEN, the *Daily News* thus speaks of medical reform as a question not simply affecting medical men, but as one of general state policy.

“We have never agreed with the successive governments of this country who have thought that nothing should be done to reform the laws of the medical profession till its members are all agreed that those laws shall be. If we had waited for all the landlords to agree about the corn-laws, when should we have got free trade? Medical law is not a question of the internal organization of the profession, but a question involving the relation of a body of men to the State. The less the law interferes with the professional organization of the medical body, the better will it be both for the profession and the State. What is now wanted is rather that the State should relax the chains of law with which it has tied down so many medical institutions, than that it should construct new special laws. In short, what is wanted, is an introduction of the free trade principle into physic. Let all medical men be properly educated and properly examined, but, having once gained a legal diploma, let them practise what branch of their profession they please, in whatever part of the kingdom they like. Previous Governments have asked for an impossible unanimity amongst medical men before any step was taken. This was absurd; but just now the nearest attainable approach to that unanimity is presented by the medical profession.”

We cordially congratulate the Association and the friends of medical reform generally, upon having the enthusiastic support of so influential an organ of public opinion as the *Daily News*.

ORIGINAL COMMUNICATIONS.

A CASE OF INTESTINAL OBSTRUCTION
ARISING FROM INTERNAL STRANGULATION:
WITH A TABLE OF CASES.

By JOSEPH HINTON, M.R.C.S.L.

(Read before the Bath and Bristol Branch of the Provincial Medical and Surgical Association, March 24, 1853.)

THE increasing importance of that class of diseases commonly styled Intestinal Obstruction, and the large mortality which still attends these disorders, must be my excuse for occupying the time of this branch of the Association by the brief detail of a solitary case. Still, as isolated cases may yet contain some facts leading to the more successful treatment of the disease, I would direct attention to the case itself, and to the remarks appended to it.

CASE. About six months previous to the fatal attack, W. P., aged 16, a collier, suffered from an attack of constipation, attended by serious symptoms of inflammatory action in the caecal region. These symptoms were relieved by leeches, calomel and opium, etc., the opium being exhibited freely.

On the night of Monday, October 1st, 1852, having had a slight motion during the evening, he went to bed in perfect health, but was roused during the night by a sudden attack of severe pain in the bowels, and almost immediately he vomited. He took some brandy, without relief; and early in the morning his mother came to my surgery, requesting some aperient medicine, which my assistant gave her. Recollecting his old attack, I called; and finding that the aperient had not acted, but that the vomiting had rather increased, I ordered it to be immediately discontinued. The boy's appearance was anxious; his tongue was coated, and already becoming dry; and his pulse was quick. The abdomen was tense, and slightly tender in the caecal region, which appeared, if anything, more prominent than on the opposite side; there was no dullness on percussion, but rather resonance. Mustard poultice, followed by poppy fomentation, was applied to the abdomen. And

Rx.—Pulveris ipecac. compositi gr. x.
Hydrargyri chloridi gr. ij.

Ft. pulvis omni hora sumendus.

Sumat olei ricini 3 iij mane.

I will not detail the progress of the case. Suffice it to say, that under the plan mentioned, he improved in every respect. The vomiting abated and disappeared; the tongue became moist; but although the oil was not rejected, it did not act. On the following day, I ordered him three grains of solid opium; and, about three hours afterwards, an injection of castor-oil, with eight or ten drops of croton oil, was given. This speedily returned, bringing with it a very large, bulky, feculent motion, giving great relief, which lasted throughout the day. Small doses of opium were continued.

During the following day, October 20th, partial motions, less copious, and one containing blood (as reported), followed the use of injections; but towards evening, pain returned slightly, and although he did not vomit, his countenance was more anxious, and his tongue drier. From this time he gradually became worse. Opium was given freely whenever he was in pain, and relieved him for a time. Purgatives were omitted, and the vomiting did not return. Croton oil, tartar emetic, and other injections were employed without avail. The abdomen was more tense; and the quantity of urine passed was scanty. On the fifth day of the attack, seeing that he did not improve, I began seriously to think of an operation, and expressed my opinion plainly to the parents, who consented to let me perform any operation I chose. The next morning, therefore, I sent for my friend Mr. Scott, of Newport, determining that, if his view of the case in any way coincided with my own, I would hesitate no longer. I found my patient considerably worse

on that morning; much weaker; delirious at times; and before Mr. Scott arrived, death terminated my hopes.

EXAMINATION OF THE BODY. On the day after death, I opened the abdomen, as I had intended doing during life, by an incision about nine inches in length, from above the umbilicus to the pubes. The distended intestines immediately filled up the opening; and among the convolutions I noticed one considerably darker than the rest. Having, however, determined to search for the healthy contracted intestine below the obstruction, I turned the convolutions on one side, and soon found the colon contracted, and white. I endeavoured to trace it backwards, but the distended small intestine interfered. Returning, therefore, to the dark convolution, I found that it was a portion of small intestine, about eight or ten inches in length; and on turning it aside from the others, the disease was easily exposed. A thin band of membrane ran from the termination of the appendix, and appeared attached to the caecum. On gently touching it with a bistoury, it was divided, and the intestine released, and the strangulated bowel was directly filled with the gaseous contents of the intestine above.

REMARKS. *Diagnosis.* Without discovering the character of the obstruction, our diagnosis is incomplete. I am not going to enlarge upon this most important topic, but shall merely notice those symptoms which appear to direct us towards a class remediable, with very rare exceptions, by operative interference alone. For practical purposes, internal strangulation, intussusception, and twist or malpositions of the intestines, resemble each other in symptoms, especially in the character of the attack. In all it is *par excellence* sudden. Health and disease closely approach each other: the past has been health, its future a state of extreme suffering. Thus many cases resemble strangulated hernia; and, in fact, the diseases are often the same. Not only is there a change perceptible to the patient, but vomiting, as in the case related, may occur at the very moment of seizure, showing that some of the actual consequences of the disease supervene immediately: and vomiting generally is an early symptom. From my own limited experience, added to the examination of reported cases, I am compelled to think that the period when vomiting presents itself in the course of the attack, depends not, as some have supposed, upon the height of the obstruction in the alimentary canal, but upon the character of the obstruction itself; that when the disease consists in one of the three alterations just mentioned, there it is pre-eminently the *early* symptom, and *vice versa*. The reason is perhaps uncertain; but may it not be accounted for by supposing that, in these alterations, the vermicular action is arrested at once; and that, this returning upon itself, vomiting ensues? As ileus, the disease most likely to be confounded with these, is, if I may be allowed the term, a constitutional disorder, the symptoms altogether, and vomiting especially, are less sudden. In the table will be found a few cases where vomiting appeared early; but they do not belong to this class. Such are cases 118 and 136; but the previous history shows that the cause of its early appearance was rather connected with disordered stomach than obstruction of the bowels. A few other instances of sudden attack will be found in the table, but generally with some distinguishing feature denoting their character.

The history is an important help in diagnosis. Here inflammatory action had existed previously at the same spot; and it is very probable that membranous bands were then formed. The urine was scanty. By some this is supposed to denote the height of obstruction in the canal; but even allowing this, it does not inform us of the situation where the obstruction exists, and hence is of little value. The previous history, the prominence, and the pain, all pointed to the caecal region. The latter symptom, however, cannot be relied on. In strangulated hernia, for example, how frequently is the pain referred rather to some point in the abdomen than to the hernial protrusion. In some cases, as No. 15 in the table, the pain has even existed on the opposite side to the seat of obstruction; and in opera-

ting, it is now generally considered that the pain should not lead us to prefer one part of the abdomen to another.

The sex of the patient has been considered to have some weight in the diagnosis of membranous bands; it being thought that the female sex are more exposed to their formation, from the mobility of the contents of the abdomen. Of forty-two cases mentioned in the table, thirty were males, only twelve females.

There is another important point in the case, which certainly misled me in the prognosis for some hours: I mean the copious action of the bowels, which followed the administration of the croton-oil injection. I am well aware that, in intestinal obstruction, the bowels are frequently relieved, the inferior portion alone evacuating its contents; but the relief, if any, is transient. It will be found by reference to the table, that where mention is made of the bowels, it is rather the exception than the rule that they should remain unacted on; but that relief does not attend their action. Here, however, relief was most marked. It was far from transient, lasting over twenty-four hours; and the motion was so copious, that it led me to hope that the obstruction was removed. Further, several less copious motions followed. The *post mortem* examination proved how fallacious had been the hope. From this, may we not deduce the general rule, that, when the relief following an evacuation in intestinal obstruction is not permanent, the disease is probably still unremoved; and that our treatment has been hitherto unsuccessful?

Treatment. Purgatives were omitted, experience daily proving this the more rational plan. Opium was freely given, and from it alone did the patient experience much relief. The vomiting diminished after the omission of purgatives; nor does it generally appear to be urgent where these are avoided. When it is so, total cessation from swallowing anything in bulk, so that the stomach may not be excited to action; the free exhibition of opium; ice, on which two or three drops of dilute hydrocyanic acid may be placed, with an occasional mustard poultice to the epigastric region,—appear to be the plans which meet with the greatest success. All kinds of aperients must especially be omitted, and all attempts at moving the bowels be confined to the lower portion of the canal. On the various remedies which have been adopted, and which from time to time have been successfully (?) employed at this portion of the tube, I will not enlarge. All the different remedies, from tobacco to simple warm water, have had their advocates. Of the depressing class, tartar emetic is the safest and most easily managed, having all the advantages without the deadly effects of tobacco. The gradual injection of large quantities of warm water has often relieved the patient; but still, in the successful cases, it is not always easy to determine the character of the obstruction. Nor should this portion of the tube be forgotten as a receptacle for nutriment, in the shape of strong beef-tea injections; sufficient opium being added to prevent their return. They may be given at regular intervals of a few hours, according to circumstances.

If we can be in some measure certain as to the diagnosis of these cases, the proposed operation appears to offer the sole rational grounds of success; and in this case I regret that it was delayed so long. As the *post mortem* examination proved, the diagnosis was correct; the case was comparatively easy. In performing the *post mortem* examination, I acted as if operating. The contracted intestine, though easy to discover, was difficult to trace backwards. Here, however, it would not have been necessary; for the strangulated intestine, being large, was easily brought into view, and its dark colour distinguished it at sight. In less favourable cases, the only guide to be depended upon is the collapsed intestine, which must be carefully and patiently traced until the obstruction is reached.

The following table contains a brief outline of the histories of 137 cases, collected from various sources. In all, either the disease was discovered by *post mortem* examination, or was otherwise evident. The exceptions to this are

the case of Mr. J. Soden's, No. 60, which, as he was present, I thought he might explain his own impression; and No. 61, a case of my own, in which I state my own impression. I may also state that many cases are not mentioned, which are elsewhere reported, merely because the character of the symptoms is so indistinctly portrayed in the author's remarks. The cases are arranged for convenience in three classes:—1. Cases in which the obstruction arose from causes exterior to the intestine; 2. Cases where the intestine itself formed the obstruction; 3. Cases in which obstruction was produced by faeces or foreign bodies within the intestine.

These cases may also be divided into those in which the symptoms appeared suddenly, and those in which the disease came on gradually. Of the sudden cases, no less a number than sixty-nine were cases of intussusception, internal strangulation by peritoneal bands or adhesions, or malposition; and many of the remainder have the sudden attack explained by the remarks appended. Of the gradual cases, nine belong to the class mentioned, but many are scarcely cases of obstruction.

Abstract of the Table.

	Internal strangulation.	Ileus.	Intussusception.	Enteritis, etc.	Stricture.	Scirrhus.	Foreign bodies.	Total.
Sudden	49	4	20	2	2	3	4	86
Gradual	7	5	4	2	22	7	6	51
Total	56	9	24	4	24	10	10	137

Of the cases of ileus, three, Nos. 57, 58, and 59, reported by Dr. Abercrombie, have an indistinct history of the attack; and it appears to me that he has described their condition when he was called in to see them, not the history of the attack. No. 54 had nothing to distinguish it. Of the four cases of foreign bodies, one, No. 133, was attended by jaundice; the others, Nos. 134 and 135, were accompanied by paroxysmal pains, as in the passage of biliary calculi. No. 136 might probably have been diagnosed by attention to the history. Of the cases of scirrhus, etc., No. 118 owed its sudden nature to food swallowed unmasticated; in No. 123, the disease could be felt; No. 99 had hernia also; while Nos. 117 and 122 were not to be distinguished.

Of the gradual cases, those of invagination were remarkably chronic; while of the five cases of strangulation, No. 114 had stricture of the rectum also, possibly the cause of death, while some of the others might also be distinguished.

In concluding these hasty remarks, I would ask, Is not the treatment of hernia most applicable to these cases? Release the intestine, and you destroy the disease. True it is, we may not destroy its consequences; but do not these frequently, if not constantly, arise from the delay? Such is the conclusion at which I have arrived; and, were I in the position of the patient, I would say, "Defer not that operation; call it not a *last resource*; for it is not so much its intrinsic danger as its tardy adoption that renders it worthy of this name." There is no longer that intense objection to opening the abdominal cavity which formerly existed. Women recover from operations for ovarian disease, and after the Caesarean section, in which an important viscus is also wounded: why should they not also recover from operation for intestinal obstruction? Nor has success been altogether denied to those who have thought it expedient to give the patient the benefit of this *ancient remedy*. Case No. 19 is a case in point; a case in which the operator considered it less injurious to puncture the intestine in three different places, than to confine the contents

[Continued at page 433.]

Table of Cases of Intestinal Obstruction, shewing the Character of the Symptoms and the Nature of the Obstruction.

A. OBSTRUCTION FROM CAUSES EXTERNAL TO THE INTESTINE.

No.	Sex and age.	Character of symptoms.	Action of bowels.	With or without relief.	Cause.	Result.	Nature of disease.	Duration.	Authority.	Treatment: and remarks.
1	F. 50	Gradual: attack sudden.				D.	Obturator hernia.	4 wks.	Mr. Stanley, Lancet, May 1851.	History indistinct. While coughing, felt sudden descent of hernia in left groin. Operation without relief.
2	F. 55	Sudden.				R.	Obturator hernia.		Mr. Obrè, Med. Chir. Soc., June 24, 1851.	Oper. in femoral region: reduction of strang. bowel.
3	F. 49	Sudden.	Yes.	No.		R.	Obturator hernia.	4 days.	Mr. B. Cooper, Med. Times, Jan. 29, 1853.	Explor. oper. in femor. reg.; accidental reduct. during. exam. Died subsequently of bronchitis. Health ailing since fall; but attack sudden.
4	M. 74	Gradual: attack sudden.			Fall.	D.	Diaphragmatic hernia.	9 days.	Mr. Erichsen, Lancet, Feb. 9, 1850.	Health ailing since fall; but attack sudden.
5	M. 14	Sudden.			Wnd.	D.	Diaphragmatic hernia.	2 days.	Med. Times, Feb. 5, 1853.	Usual remedies.
6	M. 27	Sudden.	No.			D.	Mesocolic hernia: jejunum and ileum between layers of left mesocolon: ileum constricted 2 inches above ileo-caecal valve, by sharp edge of mesocolon.	41 hours.	Dr. Peacock, London Journ. of Med., Oct. 1849.	Usual remedies to procure action of bowels and relieve vomiting. The hernia evidently of long standing.
7	F. 24	Sudden.	No.			D.	Mesocolic hernia: mesocolon falling over and strangulating jejunum.	2 days.	Mr. Charlton, Med. Gaz., Sept. 12, 1851.	Aperient enemata. Had several attacks.
8	M. 25	Sudden.	No.		Fall.	D.	Strang. of jejunum in slit of mesentery.	2 days?	Mr. Bailey, Prov. Med. and Surg. Journ., April 14, 1852.	Bleeding, opium, etc.
9	M. 15	Sudden.				D.	Strang. of ileum through rents in mesentery.	10 days.	Dr. Biaggini, Lancet, June 5, 1847.	
10	M. 21	Sudden.	No.			D.	Strang. of ileum by mesentery and bands.	9 days.	Mr. Robinson, London Journ. of Med., July 1851.	Calomel and opium, etc.
11	M. 22	Sudden.	Yes.	No.	Indigestion	D.	Omentum partly strang. ileum.	6 days.	Mr. B. Phillips, M. Gaz. Aug. 8, 1851.	Bleeding, leeches, cal., and opium.
12	M. 32	Sudden.	Yes.	No.		D.	Ileum twisted and strang. by omentum: hernia also.	4 days.	Mr. Paget, Med. Times, Sept. 18, 1852.	Explor. oper. in inguinal region without relief.
13	M. 58	Sudden.	No.			D.	Growth of omentum round knuckle of ileum.	3 days.	Mr. Robinson, London Journ. of Med., July 1851.	Aperients: enemata.
14	M. 50	Sudden.	Yes.	No.	Blow.	D.	Partial hernia: one side of intestine undiscovered.	30 hours.	Mr. Hey, Med. Gaz., Oct. 28, 1849.	Bleeding, leeches, etc.
15	M. 46	Sudden.	Yes.		Strain.	D.	Intestine strang. by appendix. Pain on left side.	7 days.	Mr. Gay, Ibid., Aug. 29, 1851.	Castor oil enema: calomel: explor. oper. in median line, div. of band, and release of intest.: d. in 22 hrs.
16	F. 37	Sudden.	Yes.			D.	Intestine strang. by appendix.	5 days.	Dr. Abercrombie, Dis. of Stomach, etc.	Usual remedies.
17	M. 31	Sudden.	No.			D.	Intestine strang. by appendix.	4 days.	Mr. Hancock and Mr. Willing, London Journ. of Med., March 1851.	Cal. and opium. Oper. was proposed, but refused.
18	F. 24	Sudden.	Yes.	No.		D.	Diverticulum of ileum twisted round intestine, and attached in right iliac fossa.		M. Bouvier, Gaz. Méd. de Paris, April 12, 1851.	Old adhesions: acute peritonitis after delivery: death.
19	M. 24	Sudden.	No.			R.	Portion of ileum strang. by small intest.		M. Reali, Révue Méd.-Chir., Janvier 1851; Prov. M. and S. Journ. June 11, 1851.	Oper. in med. line: div. of stricture with success.
20	M. 31	Sudden.	Yes.	No.		D.	Portion of ileum strang.	5 days.	Dr. Abercrombie, Dis. of Stomach.	Usual remedies.
21	M. 31	Sudden.	No.			D.	Portion of ileum strang. Diseased mass also existed in abdomen.	3 days.	Dr. Abercrombie, Dis. of Stomach.	Usual remedies.

No.	Sex and age.	Character of symptoms.	Action of bowels.	With or without relief.	Cause.	Result.	Nature of disease.	Duration.	Authority.	Treatment: and remarks.
22	M. 78	Sudden.	No.			D.	Hernia strang. high up. Blighted testis.	4 days.	Dr. Turley, Prov. Med. and Surg. Journ., April 15, 1851.	Opium. Refused explor. oper.
23	M. 30	Very sudden.	No.		Supper.	D.	Internal strangulation by band.	14 days.	Dr. Oke, <i>Ibid.</i> , July 7, 1852.	Opium: beef-tea injections: bleeding, etc.
24	F. 50	Sudden.				D.	Intern. strang.: umbilical hernia.	24 hours.	Mr. Paget, Med. Times, July 31, 1852.	Explor. oper. at umbilicus without relief.
25	M. 16	Sudden.	Yes.	No.		D.	Intern. strang. by band at cæcum.	6 days.	Mr. Hinton, Present paper.	Cal. and opium: aper. injections.
26	M. 11	Sudden.				D.	Internal strangulation.	14 days.	Dr. Druitt, Med. Chir. Soc.	Oper. in med. line: bowels gave way during manipulation. D. in 24 hours.
27	F. 19	Sudden.	Yes.	No.		D.	Internal strang.: band fr. mesent. to fundus uteri.	20 days.	Mr. Fergusson.	Oper. in median line: relief of strict.: but death in 17 hours.
28	M. 20	Sudden.				D.	Internal strang. of ileum, by small intest. and membranous band.	13 days.	Dr. Bird, Mr. Hilton, Med.-Chir. Trans., vol. xxx.	Oper. in median line: d. in 10 hours. Attack very distinctly marked; but sympt. not urgent, vom. appearing on 5th day.
29	M. 60	Sudden.				D.	Constricted condition of cæcum: fresh morbid matter had formed tough band strangulating intestine.	20 hours.	Mr. Brown, Association Medical Journal, Feb. 11, 1853.	Usual remedies.
30	F.	Gradual.				D.	Strangulation of ileum by old bands.	10 days.	Mr. Brown, <i>Ibid.</i>	Usual remedies. Patient had for some time complained of pain across umbilicus; also in cæcal region, where circumscribed hardness could be felt: frequent constipation.
31	M. 35	Sudden.	No.			D.	Internal strangulation.	7 days.	Mr. Curling, Lancet, July 20, 1850.	Explor. oper. in groin without relief.
32	M. 21	Sudden.				D.	Internal strangulation; also hernia.		Mr. Solly, <i>Ibid.</i> , July 13, 1850.	Explor. oper. in groin; disease not discovered.
33	F. 50	Sudden.	Yes.	No.	Over-reach.	D.	Apparent hernia. To internal ring portion of ileum was attached firmly, and opened during operation. A band stretched from omentum to right groin, immediately under which was the small coil of intestine connected with internal ring.	17 days.	Mr. B. Phillips, Med. Gaz., August 8, 1851.	Explor. oper. in inguinal region: escape of purulent matter, followed by relief. Three days before death, symptoms returned and ended fatally.
34	M.	Sudden.				D.	Intern. strang. of ileum by band.	24 hours.	Mr. Callaway, Lancet, vol. for 1830, p. 743.	Bleeding, calomel, etc.
35	M. 63	Sudden.	No.			D.	Intern. strang. of ileum; also old hernia.	3 days.	Dr. Crisp, <i>Ibid.</i> , May 20, 1847.	Usual remedies.
36	F. 24	Sudden.				D.	Strang. of ileum by band, from appendix to another portion of ileum.	3 days.	Mr. Marshall, Lancet, Jan. 9, 1847.	Bleeding, calomel, opium, etc.
37	M. 16	Gradual.	No.			D.	Intern. strang. by band of three feet of intestine.	15 days.	Dr. Beilby, Edin. Med. and Surg. Journ., 1835.	Mercury. Attack came on after diarrhoea for one day. Large amount of intestine strangulated may account for gradual character.
38	M. 12	Sudden.			Strain in wrestling.	D.	Band from umbilicus strang. intestines.	7 days.	Dr. Berncastle, Lancet, Feb. 15, 1845.	Various remedies: injections, etc.: frictions with croton oil.
39	F. 20	Sudden.	No.			D.	Ileum strang. by band from colon to spine. Peritonitic effusion; intest. very vascular.	19 days.	Mr. C. R. Thompson, Med. Gaz., July 12, 1851.	Bleeding: purgatives, injections. Exciting cause of attack was wet feet and suppressed catamenia.
40	F. 23	Sudden.	No.			D.	Two feet of ileum strang. by band from mesentery to another portion of ileum. Bowels agglutinated by recent lymph.	4 days.	Mr. C. R. Thompson, <i>Ibid.</i>	Injections: wine: beef-tea, brandy.
41	M. 40	Sudden.	Yes.	No.		D.	Strang. of lower part of ileum by bands.	6 days.	Mr. Robinson, London Journ. of Med., July 1851.	Purgatives: enemata: opiate, etc.

No.	Sex and age.	Character of symptoms.	Action of bowels.	With or without relief.	Cause.	Result.	Nature of disease.	Duration.	Authority.	Treatment: and remarks.
42	M. 34	Sudden.	No.		Strain.	D.	Ileum bound down to iliac fossa by bands.	8 days.	Mr. Robinson, London Journ. of Med., July 1851.	Bleeding: leeches: calomel, etc.
43	M. 17	Sudden.	No.		Several attacks.	D.	Ileum bending down and attached to pelvis.	5 days.	Dr. Abercrombie, Diseases of Stomach, etc.	Bleeding: blisters, etc. Each separate attack sudden.
44	F. 14	Sudden.				D.	Lower portion of ileum involved in old disease, and completely confined by false membrane.	3 days.	Dr. Abercrombie, <i>Ibid.</i>	Usual remedies. Had never complained before the sudden attack.
45	F. 61	Sudden.	Altern. with diarrhoea.			D.	Cæcal ulcers and fistulæ; colon and ileum firmly agglutinated.	3 mths.	Dr. Jenks, Association Journal, Feb. 11, 1853.	Camphor relieved extreme flatulence: diarrhoea uncontrollable.
46	F. 32	Gradual: rather sudden.				D.	Bowels agglut. together.	10 days.	Mr. Erichsen, Lancet, Feb. 9, 1850.	Bleeding: leeches: injections.
47	M. 28	Sudden.				D.	Old disease of bowels. Intest. matted together strang. loop of ileum.	4 days.	Dr. McCarogher, Med. Gaz., Aug. 24, 1849.	Injections, etc.
48	F. 14	Gradual.	Diarrhoea.	No.		D.	Intest. matted together.	5 mths.	Mr. I. B. Brown, Lancet, July 13, 1850.	Hyd. c. cretâ, Dover's powder, etc. Solid tumours in abdomen had been mistaken for ovarian tumour; but disappeared on discharge of feces.
49	M. 4	Sudden.	No.			D.	Intern. strang. by another portion of intestine.	2 days.	Mr. Simon, Prov. Med. and Surg. Journ., Oct. 13, 1852.	Aperients, etc.
50	F. 60	Very gradual.				D.	Diseased mass round rectum causing stricture; intestine itself apparently healthy.	Several weeks.	Dr. Abercrombie, Diseases of Stomach, etc.	Usual remedies.
51	M.	Gradual.				D.	Tuberc. dis. of mesent. glands. Calculi making exit through abdom. parietes.	Months.	Dr. Oke, Prov. Med. and Surg. Jour., July 7, 1852.	The case resembled more strict. rect.
52	F. 65	Gradual.				D.	Diseased uterus.	Years.	Mr. Gay, Lancet, June 7, 1851.	Amussat's operation.

B. OBSTRUCTION PRODUCED BY THE INTESTINE ITSELF.

53	M. 50	Gradual.	Yes.	No.		D.	Ileus: dilated and contracted portions.	2 weeks.	Mr. B. Phillips, Med. Gaz., Aug. 8, 1851.	Calomel, colocynth, etc. Explor. oper. in umbilical region without relief.
54	M. 5	Sudden.				D.	Ileus: three contracted portions: undigested food.	3 days.	Dr. Cholmley, Guy's Hosp. Rep., and Prov. Med. & Surg. Journ., April 16, 1851.	Aperients: cal.: leeches: bleeding. Twisted about in bed as from colic.
55	M. 40	Gradual.	Yes.	No.		D.	Ileus: small intestines uniformly distended.	10 days.	Dr. Abercrombie, Diseases of Stomach, etc.	Usual remedies.
56	F. 20	Gradual.	No.		Cold.	D.	Ileus: small intestines distended.	10 days.	Dr. Abercrombie, Dis. of Stomach.	Bleeding, warm bath, etc.
57	F. 70	Sudden?	No.			D.	Ileus: small intestines distended.	2 days.	Dr. Abercrombie, Dis. of Stomach.	Bleeding, warm bath, etc. Though attack was apparently sudden, bowels had been confined some days.
58	M. 19	Sudden?				D.	Ileus: colon gangrenous.	4 days.	Dr. Abercrombie, Dis. of Stomach.	Bleeding, etc.
59	M. 19	Sudden?	Yes.	No.		D.	Ileus: small intestines gangrenous.	10 days.	Dr. Abercrombie, Dis. of Stomach.	Bleeding. Characters of this and of preceding case very indistinct: merely "was affected thus, and had been ill so many days."
60	M. 60	Sudden.	Yes.	No.	Crush.	R.	Ileus?	14 days.	Mr. Soden, Prov. Med. and Surg. Journ., March 17, 1852.	Expectant treatment: opium: ice: nutritive enemata.
61	M. 45	Gradual.	Yes.	Yes.		R.	Ileus.	4 days.	Mr. Hinton.	Bleeding: leeches: inject. of tart. em., cal., and op.
62	F. 60	Sudden.	No.			D.	Intussuscept. of ileum into colon.	4 days.	Dr. Abercrombie, Dis. of Stomach.	Usual remedies.
63	M. 60	Sudden.	No.			D.	Intussusceptio.	3 days.	Dr. Abercrombie, Dis. of Stomach.	Usual remedies.

No.	Sex and Age.	Character of symptoms.	Action of bowels.	With or without relief.	Cause.	Result.	Nature of disease.	Duration.	Authority.	Treatment: and remarks.
64	M. 2½	Sudden.	Yes, blood.	No.		D.	Intussusceptio: the intussuscepted portion protruding at stool. It commenced from the middle of arch of colon.	3 days.	Dr. Abercrombie, Dis. of Stomach.	Usual remedies.
65	6 mts.	Sudden.	Yes, blood.	No.		D.	Intussusception of cæcum into colon.	4 days.	Dr. Abercrombie, Dis. of Stomach.	Usual remedies.
66	M. 37	Sudden.			Dose of rhubarb.	D.	Intussusception.	8 days.	Mr. R. Jones, Lancet, Dec. 20, 1851.	The attack apparently induced by action of rhubarb.
67	6 mts.	Sudden.	Blood.			D.	Intussusception: ileum into cæcum.	4 days.	Mr. Clark, Lancet, Aug. 25, 1850.	Pulv. Doveri.
68	8 mts.	Sudden.				D.	Intussusception: the intest. protruding at anus.		Dr. Steele, Lancet, June 23, 1849.	
69	4 mts.	Sudden.				D.	Intussusception of colon into rectum.	2 days.	Dr. Steele, Lancet, June 23, 1849.	Castor oil, etc.
70	M. 4ms.	Sudden.				D.	Intussusception of colon into rectum.	2 days.	Mr. Nind, Lancet, June 23, 1849.	Castor oil, etc.
71	Inf. 4ms.	Sudden.	Blood.			D.	Intussuscept. of ileum and cæcum into colon.	3 days.	Dr. Alex. Monro, Med. Gaz., March 2, 1833.	Injection of castor oil.
72	M. 28	Gradual.	Diarrhœa.			D.	Intussuscept. of ileum and cæcum into sigmoid flexure.	Weeks.	Mr. B. Phillips, Med. Gaz., March 2, 1833.	Peculiarly chronic case: no obstruction.
73	Inf. 5ms.	Sudden.	Blood.			D.	Intussuscept. of ileum and cæcum into colon.	3 days.	Mr. Blizard, Med.-Chir. Trans. 1815.	
74	M. 9ms.	Sudden.	Blood.			D.	Intussuscept. of ileum and cæcum into colon.	3 days.	Mr. Cunningham, Med. Gaz., Sept. 15, 1838.	Leeches: enemata.
75	M.	Sudden.	Yes.	Yes.	Supper.	R.	Intussusception: 23 in. passed at stool.	15 days.	Dr. Thomson, Edin. Med. and Surg. Journ., 1835.	Remedies not mentioned.
76	M. 23	Sudden.	Yes.	Yes.		R.	Intussusception: intestine discharged.	18 days.	Dr. Thomson, Edin. Med. and Surg. Journ., 1835.	Remedies not mentioned.
77	M. 45	Sudden.	Yes.	Yes.	Strain.	R.	Intussusception: 18 in. passed.	14 days.	Dr. Thomson, Edin. Med. and Surg. Journ., 1835.	Remedies not mentioned.
78	M. 37	Sudden.	Yes.	Yes.		R.	Intussusception: 18 in. passed.	20 days.	Dr. Thomson, Edin. Med. and Surg. Journ., 1835.	Remedies not mentioned.
79	M. 40	Sudden.	Yes.	Yes.		R.	Intussusception: intestine passed 10 inches.	14 days.	Dr. Thomson, Edin. Med. and Surg. Journ., 1835.	Mercury.
80	F. 40	Gradual.	Yes.	Yes.		R.	Intussusception: intestine passed.		Dr. Thomson, Edin. Med. and Surg. Journ., 1835.	Remedies not mentioned.
81	F. 56	Sudden.	Yes.	Yes.		R.	Intussusception: 40 in. passed.	7 days.	Dr. Thomson, Edin. Med. and Surg. Journ., 1835.	Remedies not mentioned.
82	M. 6	Gradual.	Yes.	Yes.		R.	Intussusception: intestine passed at stool.	5 days.	Dr. Thomson, Edin. Med. and Surg. Journ., 1835.	Remedies not mentioned.
83	F. 30	Sudden.	Yes.	No.		D.	Intussusception: 2 ell in length passed away.	8 days.	Dr. Thomson, Edin. Med. and Surg. Journ., 1835.	Remedies not mentioned.
84	F. 48	Gradual ill health, attack sudden.	Yes.	No.		D.	Intussusception: 10 in. passed.	30 days.	Dr. Thomson, Edin. Med. and Surg. Journ., 1835.	Bowels had always been costive: seizure quite sudden: they had not been acted on for five days previously.
85	F. 31	Gradual.	Yes.	Yes.		R.	Intussusception: 10 in. passed.		Dr. Thomson, Edin. Med. and Surg. Journ., 1835.	Bowels had been unacted on for eight days.
86	M. 24	Sudden.	Yes.	No.	Several attacks.	D.	Twist of colon: cæcum turn. upwards, & attached to colon by old adhesions.	3 days.	Dr. Abercrombie, Dis. of Stomach.	Usual remedies: opiates, etc. Vomiting not mentioned.
87	M.	Sudden.				D.	Twist of colon.	36 hours.	Dr. Ayre, Med. Gaz., Oct. 29, 1841.	Usual remedies.
88	M. 52	Very sudden.				D.	Twist of sigmoid flexure.	7 days.	Mr. Erichsen, Lancet, Jan. 26, 1850.	Operat. in median line: twist replac.: feces passed into it: bow. twice mov.: patient d. of exhaust. 11 hrs. aft. op.

No.	Sex and age.	Character of symptoms.	Action of bowels.	With or without relief.	Cause.	Result.	Nature of disease.	Duration.	Authority.	Treatment: and remarks.
89	F. 50	Gradual.				D.	Twist of sigmoid flexure.	4 weeks.	Dr. Roupell, Lancet, Aug. 9, 1851.	History indistinct: says she had been ill three days.
90	M. 20	Sudden.	Yes.	No.		D.	Inflammation of ileum.	6 days.	Dr. Abercrombie, Dis. of Stomach.	Usual remed. Had felt uneasiness for many days. Pain intense, as of peritonitis.
91	F. 3	Gradual.	Yes.	No.		D.	Upper part of small intestine gangrenous.	6 days.	Dr. Abercrombie, Dis. of Stomach.	Bleeding, etc.
92	M. 10	Sudden.	Yes.	No.		D.	Upper part of small intestine much distended, pushing down lower into cavity of pelvis.	2 days.	Dr. Abercrombie, Dis. of Stomach.	Bleeding, etc.
93	F. 22	Gradual.	Yes.	No.		R.	Inflammation of cæcum? Distinct tumour of some thickness in that part, continuing after relief of pain.	4 days.	Mr. Hinton.	Cal. and op. each gr. ij, ev. hour: leeches: frict. of ung. hyd.: inject. of tartar emet.: castor oil, etc. Grt. tenesmus foll.: relieved by opium in rectum: at least 5 ss of op. taken by mouth.
94	M. 40	Gradual.	Alter. consti. & diarr.	No.		D.	Stricture near middle of ileum from centre of periton. coat.	14 days.	Mr. Robinson, Lond. Journ. of Med., July 1851.	Bleeding: leeches: injections: croton oil, etc.
95	M. 24	Gradual.	Yes.	No.		D.	Stricture of arch of colon.	1 year.	Dr. Abercrombie, Dis. of Stomach.	Usual remedies.
96	M. 47	Gradual.				R.	Stricture of colon.	Weeks.	Mr. Clement, Med. Times, March 6, 1852.	Operation in ascending colon.
97	M. 40	Gradual.	Yes, occas. diarr.			D.	Stricture of colon.	Weeks.	Mr. Hinton.	Diarrhoea at times with difficult control: attacks simulated dis. of stomach.
98	M. 23	Gradual.				R.	Stricture of colon. Died subsequently.	Months.	Mr. Evans, Med.-Chir. Trans. vol. xxviii, p. 25.	Operation in ascending colon.
99	M. 55	Rather sudden.				D.	Stricture of colon at lower part: hernia also.	10 days.	Mr. Luke, Lancet, March 30, 1850.	Explor. oper. in groin. No relief.
100	F. 42	Gradual.				R.	Stricture of colon, prob. beyond transverse portion.	Weeks.	Mr. Hilton, Guy's Hosp. Rep., vol. viii, pt. i, p. 186.	Opium and enemata: afterwards oper. in ascending colon.
101	F. 80	Gradual.				D.	Stricture above sigmoid flexure.	Weeks.	Dr. Murer, Med. Gaz., Jan. 21, 1841.	Inject. of croton oil, etc.
102	M. 50	Gradual.				D.	Stricture of colon. Old hernia came down on fifth day: retd. with diff.: red. en masse suspected. Gt. hypertrophy of musc. coat.	13 days.	Mr. Luke, Lancet, March 30, 1850.	Explor. oper.: enemata, etc. Duration short, yet symptoms came on gradually from weariness. Hypertroph. musc. coat would probly. explain absence of constipation.
103	F. 56	Gradual.				D.	Stricture of colon.	20 days.	Mr. Avery, Med. Gaz., May 18, 1849.	Explor. oper. in groin: extended to umbilicus: art. anus formed. Death in eight hours.
104	M. 65	Gradual.	Yes.	Yes.	Dinner.	R.	Strict. of colon? Ileus?	4 days.	Mr. Hinton.	Opii gr. ij, cal. gr. i, 2ndis horis. Oleaginous and croton oil injections, both ineffectual. Inject. of tartar emet. appeared to have effect. At least gr. xx of opium were taken.
105	M. 70	Very gradual.				D.	Stricture of sigmoid flexure.	Several weeks.	Dr. Abercrombie, Dis. of Stomach.	Usual remedies.
106	M. 80	Gradual.	Yes.	No.		D.	Stricture of sigmoid flexure.	Several weeks.	Dr. Abercrombie, Dis. of Stomach.	Usual remedies.
107	F. 88	Gradual.	Yes.	No.		D.	Stricture of sigmoid flexure.	Several weeks.	Dr. Abercrombie, Dis. of Stomach.	Usual remedies. Alternately diarrhoea.
108	F. 44	Gradual.	Yes.	No.		D.	Stricture of sigmoid flexure.	Several weeks.	Dr. Abercrombie, Dis. of Stomach.	Usual remedies. Alternately diarrhoea. At one period, had no evacuation for 13 weeks.
109	F. 40	Gradual.				D.	Stricture of sigmoid flexure.	6 weeks.	Mr. Lawrence, Lancet, Aug. 9, 1851.	
110	M. 56	Gradual.				R.	Stricture of sigmoid flexure.	Months.	Mr. Field, Lancet, Jan. 19, 1850.	Operation in descending colon.
111	F. 21	Gradual.				R.	Stricture of sigmoid flexure.	Months.	Mr. Clarkson, Ibid.	Operation in descending colon.

No.	Sex and age.	Character of symptoms.	Action of bowels.	With or without relief.	Cause.	Result.	Nature of disease.	Duration.	Authority.	Treatment: and remarks.
112	F. 50	Gradual.				D.	Stricture of sigmoid flexure.	8 weeks.	Dr. Roupell, <i>Lancet</i> , Aug. 9, 1851.	Amussat's operation performed after death.
113	M. 38	Gradual.				R.	Stricture of rectum: prob. near sigmoid flexure.	Months.	Mr. Curling, <i>Med. Times</i> , Dec. 18, 1852.	Oper. in left loin. Died 5 months afterwards.
114	F. mid. age.	Gradual.				D.	Stricture of rectum: strang. of ileum & cæcum.	Weeks.	Dr. R. Bennett, <i>Med. Times</i> , Dec. 18, 1852.	Imperfect report: said to be gradual constip.: stricture prob. cause of death. Usual remedies.
115	F. 44	Gradual.				D.	Stricture of rectum.		Mr. B. W. Brown, <i>Associat. Journ.</i> , Feb. 11, 1853.	
116	M. 50	Gradual.				R.	Stricture of rectum.	Months.	Mr. Pennell, <i>Lancet</i> , May 25, 1850.	Operation in descending colon.

[Continued from page 432.]

lation and exposure necessary for the reduction of the strangulation; and I confess I am in some measure disposed to accord with the opinion. Nor was this the only point opposed to the recovery; the three punctures were subsequently found to be continuous, and required the uninterrupted suture; yet, although the operation was followed by erysipelatous inflammation, the recovery was perfect.

In the *Medical Gazette* for March 2nd, 1833, Mr. B. Phillips, speaking on this very subject, says that he has collected three hundred and thirty-two cases of gastrotomy; only forty-four were fatal. In intestinal obstruction of all kinds, curable and incurable, the mortality is far above this. I cannot but think that the cause of death after gastrotomy, when applied for the relief of intestinal obstruction, depends on the delay. That is indeed dangerous; but with an earlier adoption of the operation, and with proper precautions as to the temperature of the room, which should be raised nearly to blood-heat, I feel convinced that different results will ultimately attend the surgeon's efforts; and that success will crown his attempts at the restoration of life.

I would here tender my sincere thanks to my friend Mr. Colthurst, the honorary secretary of the Bristol Branch, for his kindness in looking out several works for me, by which I was enabled in a short space of time to add several cases to the table, which were beyond my limited means of reference; also, to Dr. Alexander Henry, who most kindly drew my attention to several other cases, and who also arranged the table in its present advantageous form for reference.

Blaina Iron Works, Monmouthshire, March 1853.

CASE OF ACUTE INTESTINAL TUBERCULOSIS.

By WILLIAM HENRY ASHLEY, M.D., Surgeon to the Kensington Dispensary.

CASE. Miss B., aged 14, of a weak and delicate constitution, not having yet menstruated, had been from an early age subject to those symptoms which mark a high degree of tuberculous dyscrasia. Her stature was exceedingly dwarfish, and the general conformation of the frame so diminutive, that she might have been considered rather of the age of ten than fourteen years. The circulation was languid; the extremities had a shrivelled appearance, and were generally cold; and the pallid surface of the body in-

dicated an impoverished condition of the blood. On many occasions she had been under medical treatment, on account of general debility and ulceration of the feet, when she had taken with much benefit the mineral acids and cod-liver oil. Several members of her family were afflicted with scrofulous cachexia; but she appeared to have been the greatest sufferer, and to have inherited the disease in a remarkable manner. The friends of the young lady attributed her illness to exposure to the night air.

January 25th, 1853. The face was pale, with oedema of the eyelids and cheeks; the expression was anxious; there was considerable emaciation; the respiration was natural; she had slight cough, with scanty viscid expectoration; there was no pain on deep inspiration. The percussion sound was clear, and there was sonorous breathing in the upper lobes of the lungs. The physical signs indicated but very partial disease of the pulmonary tissue. The pulse was small, and 120 in the minute. The cardiac sounds were normal. She had occasional febrile exacerbations, but no rigors; the epigastrium and abdomen were free from any tenderness or pain; the action of the bowels was regular, without diarrhoea; the tongue was moist and somewhat furred; the skin very dry and unperspiring; the feet and ankles were oedematous; the urine was scanty, pale, and highly albuminous; the specific gravity was not ascertained, in consequence of its paucity and involuntary flow with the motions. She had some pain over the lumbar region. I prescribed as follows:—

R. Liquoris ammoniæ citratis ʒij.
Tincturæ scillæ ʒj.
Tincturæ digitalis 3 ss.
Spiritus ætheris nitrici ʒij.
Acidi hydrocyanici diluti ʒxx.
Syrupi aurantii ʒss.
Misturæ camphoræ ʒiiss.

Misce. Sumantur cochlearia duo quartâ quaque horâ.

R. Hydrargyri cum cretâ gr. iss.
Extracti hyoscyami gr. ij.
Scillæ pulveris gr. ss.

Misce. Fiant pillulæ duæ mane nocteque sumendæ.

Hot mustard hip-baths were directed to be used, and an embrocation, as a counter-irritant, to be applied over the region of the kidneys.

February 1st. There had been some amendment since the last date. The hydropic affection had in a measure subsided, more particularly in the face; there was scarcely any cough; and she expressed herself generally relieved. The pills were directed to be omitted in the morning, and the mixture to be continued.

February 6th. Since the last date, the oedema had not decreased; and the countenance had assumed a more anxious

expression. The urine was still serous and scanty; and there was anorexia.

The symptoms continued the same, with more or less variation, until February 15th, when, for the first time, she complained of tenderness over the bowels, and pain on pressure. The medicine also occasioned distress, and was constantly rejected. Profuse diarrhoea now supervened, the evacuations consisting of coagulated blood, with reddish brown matter. There had also been much vomiting of coffee-grounds-like fluid, accompanied by hiccough.

It now became evident that glandular ulceration of the bowels was the main cause of these alarming symptoms. To alleviate her sufferings, and moderate these discharges, opium and chalk mixture were prescribed.

The patient expired on February 17th, apparently from exhausting hæmorrhage. No cerebral disturbance had taken place, and the intellect remained unimpaired to the last.

EXAMINATION OF THE BODY, twenty-seven hours after death. *External Appearance.* The body was in the last stage of marasmus. There was no cadaveric rigidity, but oedema of the feet and ankles. The vascular system and the viscera were in a state of exsanguinity.

Chest. On the superior and posterior portion of the apex of each lung, interstitial tuberculous granulations were found, very limited in number and extent. Some purulent solution had taken place; and the right lung contained a small tuberculous cavity of very recent formation. The anterior surface of the superior lobes was emphysematous. The cause of the clear percussion sound during life was thus explained. There was no oedema, but some old cellular adhesions existed between the costal and diaphragmatic pleuræ.

The heart was small, empty, pallid, and devoid of fat.

Abdomen. Near the cardiac end of the great curvature of the stomach was a patch of congestion. The lining membrane was pale, and the viscus was distended with sanguineous coffee-coloured fluid.

The liver had undergone no degeneration of its tissue into fat. It was perfectly healthy, and had contracted old adhesions to the diaphragm.

The kidneys were free from disease, but anæmic.

The mesenteric glands were natural.

The ileum assumed an unusual appearance, occasioned by a firm coagulum completely impacted in the intestine, and distending its coat to the utmost limit. When removed, the coagulum presented a perfect cast of the bowel; and on a transverse section being made, a colourless fibrinous mass was found entirely enveloped in the coagulated blood. It would be interesting to determine how this nucleated portion became denuded of its colouring matter. The mucous membrane throughout the small intestines was in parts congested; the greater portion, however, would have appeared pallid, had it not been much stained by the blood-globules arrested in the exudative process. The various outlets of hæmorrhagic exhalation were plainly indicated. The texture of the membrane was generally soft, and, in the vicinity of the glands, much thickened. The glandulæ solitariae and agminatæ were in a state of ulceration, with deposit of tubercular matter; but the lining membrane had not become involved in the destructive process.

REMARKS. The acute dropsy at the onset of the illness rendered the case complicated, and the disease less amenable to treatment. Drastic or hydragogue purgatives were inadmissible, as were also the more irritating diuretics. The most important indications were to restore the balance of the circulation, and to promote interstitial absorption. There was no evidence of intestinal ulcerations until three days before death; tenderness or pain over the abdomen having been entirely absent, and the alvine evacuations regular and healthy, without any tendency to diarrhoea.

Scrofulous disease of the glands as it existed in this case, is rarely met with, excepting as a secondary and dependent

affection, or sequence on long protracted or severe pulmonary tuberculosis. Here the disease of the lungs was of short duration, and very circumscribed; and the constitutional disturbance arising from the same was unimportant.

Although the kidneys presented no appearance of congestion, inflammation, or structural change, yet the pain at the commencement of the illness might have been occasioned by some local hyperæmia of those excretories.

The immediate cause of death was the hæmorrhage. The quantity of blood lost from the system could not be well ascertained. Besides that which was vomited, and voided by stool, the stomach was found distended with sanguineous fluid, apparently conveyed into that viscus by antiperistaltic action. The intestines also contained effused blood in a large quantity, of unusual solidity, as before related.

Although the glandular apparatus was extensively ulcerated, there was no sloughing or perforation of the coats of the bowel. The hæmorrhagic discharge appeared to arise from the diminished density and depraved condition of the circulating fluid, superadded to a lax state of the contractile vascular fibre and textures. The same causes may have operated, towards the termination of the illness, in producing the large amount of albumen excreted by the kidneys, and in occasioning the infiltration and accumulation of serum in the areolar tissue of the face and lower extremities.

FORBES WINSLOW, M.D., President, in the Chair.

TREATMENT OF CERTAIN FORMS OF ULCER. BY JOHN GAY, ESQ.

The object which Mr. GAY had in view was to propose a method of treatment for those cases in which, after an ulcer had proceeded favourably up to a certain point, the healing process became arrested, and the ulcer refused to cicatrize. He attributed this retardation to the tension of the surrounding skin, by the contraction of the cicatrix, so that it could no longer yield; and in some cases to the formation of adhesions between the cicatrix and the subjacent parts. To remedy the first of these impediments to recovery, he had made an incision just on the outside of the cicatrix. This had been followed by healing of the ulcer; and it was observed, that as the ulcer healed towards the centre, the side of the newly-made wound nearest the cicatrix was drawn inwards. In cases where adhesions had been contracted with the subjacent parts, while a part at least of the surrounding skin remained loose, he had partially dissected off the adherent portion of the cicatrix by subcutaneous incision, and shifted it over the ulcer. This plan had also been followed by success.

FORBES WINSLOW, M.D., President, in the Chair.

ALKALINE TREATMENT OF LOW INFLAMMATION. BY JOHN MARSHALL, ESQ.

Mr. MARSHALL was desirous of directing attention to the efficacy of alkaline treatment in low forms of inflammation, especially in the furunculoid epidemic at present prevailing. In the case of a man who, some days after amputation of a finger on account of serious injury, had been attacked with symptoms of pyæmia, he had administered a scruple of bicarbonate of potash, with three or four grains of sesquicarbonate of ammonia, every three hours. Under this treatment, with good diet, the man recovered. Mr. Marshall had employed the same plan successfully in several other cases of low inflammation.

He had observed in persons who died of pyæmia, that the pus and purulent fluids found in the body were acid, and contained vibrios. In less marked cases, there was also a tendency to acidity and to the formation of vibrios. This is similar to

what takes place in sour milk; and Mr. Marshall suggested that vibrios have perhaps the same relation to lactic acid as the *penicillium glaucum* has to the vinegar fermentation.

He had found in cases of whitlow, that when he had an opportunity of examining the pus at an early period, it contained either partially or fully developed vibrios almost immediately after removal from the body.

ANEURISM OF THE SUPRA-ORBITAL ARTERY CURED BY INJECTION OF A STRONG SOLUTION OF THE PERCHLORIDE OF IRON. BY JOHN GAY, ESQ.

MR. GAY read a case which had been communicated to him from Paris, in which the treatment of aneurism recommended by M. Pravaz had been successfully employed. It consists in producing coagulation of the blood within the aneurism, by the injection of a small quantity of a solution of perchloride of iron.

CRANIOTOMY IN DEFORMED PELVIS. BY ROBERT GREENHALGH, ESQ.

MR. GREENHALGH related the following case.

The subject was a milliner, aged 28, four feet in height, with considerable curvature inwards of the thigh bones. The catamenia appeared at the age of 17, and had been irregular, scanty, and painful. She had had occasional leucorrhœa. She married at the age of 21, and became pregnant. Mr. Greenhalgh was called to her in her first labour, about three years ago. He found that labour had continued for some time, and that the pains were feeble, with symptoms of prostration. The sacrum and coccyx projected forwards, and the rami of the ischium and os pubis approached each other. Having revived the patient with brandy and laudanum, he performed craniotomy, and removed the child with some difficulty. He prescribed Dover's powder and salines, with beef-tea and stimulants, if necessary. The patient recovered.

Mr. Greenhalgh strongly advised separation from her husband. In January of this year, however, she again applied to him, being five months advanced in pregnancy. She would not consent to the performance of any operation which would not give the child a chance of living. Notwithstanding the endeavours of Mr. Greenhalgh and Dr. Locock (who was consulted) to dissuade her from her purpose, she persisted in desiring the performance of the Cæsarean section. Under these circumstances, and especially under the encouragement afforded in a letter from Dr. Simpson, of Edinburgh, Mr. Greenhalgh determined to perform the operation.

On March 19th, however, at seven and a half months, labour set in. This was encouraged, under the idea that delivery might possibly be effected by the efforts of nature. This, as well as attempts to turn and to apply the forceps, having failed, and the constitutional symptoms becoming severe, craniotomy was performed, sixty-three hours after the commencement of labour. The child was a female, and weighed four and a half pounds. The distance from zygoma to zygoma was two and a quarter inches. Opium and calomel were given. The patient had a severe febrile attack, but ultimately recovered.

Dr. WINN said that, in comparing the British with the continental statistics of the Cæsarean section, we must remember that on the continent medical men are compelled to perform the operation.

Dr. CRISP observed that in America, where there is no compulsion, the Cæsarean operation has been successful.

Dr. MURPHY said, that the question of the relative merits of craniotomy and the Cæsarean section could be placed in an intelligible form, only by considering the exact circumstances under which the practitioner is placed. If we took statistics alone as a guide, we should err; and we should especially come to an unfair conclusion if we confined our attention to British statistics. In this country, surgical midwifery has made slow progress. In cases where the Cæsarean operation has been performed in Great Britain, the patient has been let alone from day to day; and at last the operation has been performed to remove the child from a dying woman. On the continent it is different, both from compulsion and from a better system of surgery. The statistics of all the cases of Cæsarean section taken together, show 158 recoveries out of 409. We must not, however, argue too much from these, because we have to consider special cases; as, for instance, one which lately occurred to Dr. Oldham at Guy's Hospital, in which he was unable to perform craniotomy, and was hence compelled to have recourse to the Cæsarean operation.

He held it as a moral principle that the life of the child was too valuable to be destroyed by craniotomy. The life of the mother is no doubt more valuable than that of the child; but if the chances of recovery to the mother, in craniotomy, are so

uncertain as to amount to only one in three, while those afforded by the Cæsarean section are at least as good, we are not justified in destroying a living child. He had carefully considered the question of retardation of the union of parts after the Cæsarean operation, by the reduction and disintegration going on in the uterus; and still believed that the operation might be performed with greater success than has hitherto attended it. Mr. Greenhalgh had been perfectly justified, both morally and professionally, in determining to perform the Cæsarean section in the case which he had related. Dr. Waller had recently performed the Cæsarean section on a woman, in whom delivery was impeded by the presence of a large tumour. A similar case had occurred in the Dublin Lying-in Hospital some years ago, under Dr. Shekelton, who was desirous of performing the Cæsarean operation. His opinion was overruled; craniotomy was performed with great difficulty; and the woman died. Dr. Waller, on the other hand, had succeeded in saving the life of the child.

MR. I. B. BROWN said, that in determining on the relative merits of craniotomy and the Cæsarean section, it was important to consider whether the child were dead or living. He believed that in many cases of narrow pelvis, delivery could be effected by turning, as recommended by Dr. Simpson. He had often seen death follow craniotomy; and this fatal result probably arose from delay. The same observation applied to abdominal surgery in general: operations had been often delayed too long. For instance, operations for hernia at one period were almost invariably fatal, because not performed early, and because the bowels were not kept quiet; while, in the present day, early operation and the use of opium are generally attended with success. The reason why the Cæsarean operation was not performed, as had been intended, in Mr. Greenhalgh's case, was that it was considered possible that the cranial bones of the fœtus at seven and a half months might have become sufficiently overlapped to be squeezed through the pelvis.

MR. J. F. CLARKE held that the previous speakers had attached too little importance to the induction of premature labour.

Dr. GRIFFITHS said that premature labour ought to be insisted on whenever possible; and if not, the forceps should be tried; and in this way the life of the mother might in many cases be saved. At the same time, the use of the forceps should not be pushed too far. The statistics of craniotomy were of little value, because the operation was so frequently successful, that the cases were often not thought worth publishing; hence we had a majority of unsuccessful cases on record. As regarded the operations themselves, there was much less danger in craniotomy than in the Cæsarean section. The former operation was probably frequently fatal from the employment of unnecessary force.

SATURDAY, APRIL 30TH, 1853.

FORBES WINSLOW, M.D., President, in the Chair.

INTUSSUSCEPTION IN A CHILD TWO YEARS OLD. BY C. COGSWELL, M.D.

The subject of the case was suddenly attacked with vomiting and other urgent symptoms, and died in forty-eight hours. At the distance of four inches from the caput cœcum coli, the small intestine began to have a red appearance. The ileum was invaginated into the colon, and apparently strangulated by the ileo-cæcal valve.

SUDDEN DEATH DURING UTERO-GESTATION. BY EDWARD SMITH, M.D.

CASE. A lady, aged 20, near the end of her second pregnancy, while lying in bed dressed, suddenly cried out, and died suddenly, after a few minutes. Dr. Smith was called, but found her dead.

EXAMINATION OF THE BODY, forty hours after death. The under part of the body was much congested, and had some petechial spots. The blood was universally black and fluid, except in the pulmonary vein, which contained a cylindrical coagulum, composed of two layers of fibrin, the outer one of which was free from red corpuscles. The heart was flaccid; its tissue was undergoing granular degeneration, especially on the right side. The right auricle and ventricle contained dark fluid blood. The left cavities were empty. The aorta at its bifurcation was very small; the external iliac artery was no larger than a swan's quill: there was no blood in the arteries. The veins were much distended: the ovarian veins were twelve in length, by three-quarters of an inch in breadth; they curved along the iliac fossæ. The stomach and intestine were much distended. The diaphragm was pushed up to between the

fourth and fifth ribs. The lungs were much collapsed; there were numerous bubbles of extravasated air beneath the pleura: there was much discolouration posteriorly. The left pleural cavity contained three ounces of sanious fluid, without coagula. The brain and sinuses were turgid: there was no effusion at the base of the brain, nor congestion of the choroid plexuses. The child was small.

Dr. Smith would attribute death in this case to suffocation, connected with atony of the system. The venous congestion was probably connected with diminished exercise, and the horizontal position in which she commonly indulged. Taking all circumstances into consideration, he would be inclined to regard the plug formed in the pulmonary vein as having been instrumental in producing death. Had the enlarged size of the veins any connexion with the smallness of the arteries?

STRICTURE OF THE URETHRA. BY JOHN CHIPPENDALE, ESQ.

The object which Mr. CHIPPENDALE had in view was to direct attention to spasmodic stricture. This might be produced by an unusual degree of acridity in the urine, arising from dyspepsia, or from causes impeding elimination by other emunctories. Spasmodic stricture under these circumstances is of constant occurrence: the urine at first flows freely; soon the stream becomes smaller, and at last ceases abruptly. This form of stricture may also be produced by mechanical causes, as unskilful introduction of instruments. This is less likely to happen from the introduction of a large than of a small instrument.

Mr. Chippendale did not believe that the urine was expelled by the action of the bladder, but that this was effected by the abdominal muscles and the diaphragm. He believed the office of the muscular structure in the bladder to be merely to adapt the organ to its contents.

The treatment consists in removing the exciting causes, in giving opium and antispasmodics. Injection of warm water into the urethra often relieves the spasm.

FORBES WINSLOW, M.D., President, in the Chair.

PURULENT INFECTION AFTER OPERATIONS ON THE GENITO-URINARY ORGANS. BY HENRY BULLOCK, ESQ.

Mr. BULLOCK divided his paper into the following heads:—
I. Secondary affections after diseases of and operations on the genito-urinary organs, not followed by a fatal result; II. Secondary affections followed by a fatal result; III. Summary of the pathology and treatment of these affections.

I. Secondary affections may follow (a) diseases of, (b) operations on the genito-urinary organs.

(a) Gonorrhoeal rheumatism is an example of this class: and Mr. Bullock related a case in illustration. He observed, that the inflammation of the joints could not have been a mere coincidence of the gonorrhoeal disease; nor was gonorrhoeal rheumatism a result of the absorption of pus. He explained it by supposing that there is an interference with the changes by which pus is formed on the mucous membrane of the urethra; that the fibrin intended for this purpose undergoes a retrograde metamorphosis, and is carried into the blood, from which, an attempt being made to eliminate it, rheumatic symptoms are set up.

(b) The non-fatal secondary affections following operations are chorea, affections of the cartilage of joints, syncope, and rigors. A case of stricture was referred to, in which the passage of the urethra was followed by rigors, succeeded by ulceration of the cartilage of the shoulder, and by pneumonia. In another instance, a woman was operated on for the removal of some necrosed portions of a tibia. Two days after the operation, phagedenic ulceration of the wound came on, and was attended by chorea. This continued for a month; and, as it subsided, the wound became more healthy. A man, aged 42, was suffering from stricture and irritable bladder. A small catheter was first passed, then Holt's dilator, which was enlarged up to No. 4. When No. 4 was passed, the patient had some shivering and giddiness, felt ill, and passed blood with his urine. At the end of a week, a No. 4 tube was passed without difficulty, though attended with pain. The patient was attacked with rigors, and had an irregular painful swelling on the back of the right hand. Leeches were applied, and calomel and opium given. This swelling proceeded some distance up the arm; and after some time subsided, but again returned. It ultimately disappeared, and an ordinary sized bougie could be passed into the urethra.

The first and last of these were regarded by Mr. Bullock as

cases of local inflammation following the introduction of an instrument into the bladder. The chorea was connected with phagedenic ulceration of the wound in the leg: here probably the amount of morbid matter absorbed was too small to produce any severe local effects on other parts of the body.

II. The fatal secondary affections following diseases of and operations on the genito-urinary organs are puerperal fever, purulent deposits, peritonitis, pericarditis, pleuritis, etc. In all these cases, the progress is rapid, and the termination fatal. Mr. Bullock related some cases, of which the following are summaries. Death occurred in all.

1. M., aged 69; lithotripsy; purulent deposits in knee-joints.

2. M., aged 38; lithotomy; secondary hæmorrhage; purulent effusion in right shoulder, and abscess extending from the seat of operation to the rectum.

3. M.; perineal section for traumatic stricture; pericarditis and pleurisy with effusion, minute purulent deposits under capsules of kidneys, and purulent effusion a round wound.

4. F., aged 42; operation for ruptured perinæum; rigors and sloughing of wound, with tenderness of abdomen; pus in Fallopian tubes; incipient peritonitis and pleuritis, and small deposits under the pulmonic pleura.

5. M., aged 16; run over by a cart: retention of urine; fistula in perinæo, and false passage; catheter introduced with much difficulty; chorea; death. Abscess by side of rectum communicating with urethra and bladder; also by side of pelvis; pubic bones had been fractured.

Similar results also follow injuries of and operations on other parts, as in the following cases.

6. F., aged 12; injury to leg from fall; pericarditis and pleuritis; and pus beneath periosteum of tibia and fibula.

7. F., aged 46; wound in hand with rusty nail; opening of abscess; purulent deposits in right knee, and in right wrist and shoulder joint, with ulceration of cartilage; also pus in left knee.

The points worthy of notice in these cases, as appeared in their detailed history, were the variety of situations in which the purulent deposits occurred; the comparatively small amount of pain in the part secondarily affected; and their universally fatal termination in spite of treatment.

III. Phlebitis has been generally assumed to be the primary cause of secondary purulent affections; an opinion which was first opposed by Mr. Henry Lee. In the cases related, the veins were sometimes thickened in the neighbourhood of the original seat of injury; but there was no disease in those at a distance. Considering the cases of undoubted purulent infection, in which no phlebitis can be detected, we must look further for the cause. The inflammation of the veins, when present, may be only a portion of the general inflammation. Mr. Bullock believed that purulent infection was a poison-disease. This view he believed to be supported by the circumstances attending puerperal fever, which are similar to those of other epidemic diseases. He believed that the fibrin which should form pus in the seat of injury or operation, undergoes a retrograde metamorphosis, and is again carried into the circulation; and that in the attempt to eliminate it, secondary purulent deposits are formed.

The treatment must be directed to interrupt and destroy the morbid development; and when pus is formed, it must be evacuated as soon as possible.

DR. DRUITT said that Mr. Bullock's paper pointed out in a measure the degree to which we may arrive in the doctrine of unity of disease. Inflammation is almost always traceable to the presence of a poison in the blood. The most simple form arises from the ingestion of non-convertible or badly convertible aliments; such as substances producing urtiaria. Examples are also afforded in the determination of blood to the fauces, produced by iodide of potassium; in the exanthematous affections produced by copaiba or cubeba in large doses; and by specific morbid poisons, such as the exanthemata. Another set of poisons is produced in the blood by perversion of the reparative processes. Mr. Bullock's cases had proved that the blood-plasma may undergo a retrograde metamorphosis, so as to render it a poison, giving rise to morbid phenomena. Within the last twelve months there has been a remarkable pyrogenic constitution, as shown in the prevalent furuncular affection.

The treatment in these cases should consist of, 1. Elimination: 2. Opium, to quiet the nervous system: 3. Such means as may render the blood less susceptible of the retrograde metamorphosis. With regard to the latter indication, the means for fulfilling it is a desideratum. Dr. Drutt had been in the habit of giving, in cases of labour, sulphate of zinc three or four days after parturition; he had also given with benefit sulphate of iron and quinine in cases of suspected puerperal fever. Pelas has been successfully treated in Edinburgh.

chloride of iron. Dr. Druitt had not had an opportunity of trying this remedy; but he would suggest its employment in cases of the kind under consideration.

Dr. CRISP suggested a trial of the alkaline treatment, as recommended by Mr. Marshall in the treatment of the prevailing funicular affections.

Mr. DENDY did not think that the presence of a poison in the blood will explain all the phenomena which occur in the secondary affections: a predisposing cause is afforded by systemic debility. Early treatment is important.

Dr. DANIELL said that the cases related conveyed the important lesson—that, before operating, surgeons should inquire into the state of health of the patient, the epidemic constitution, and other circumstances.

Mr. HENRY LEE believed that *real* purulent infection—from the absorption of pus into the circulation—is a very rare occurrence. There is a development of cells and white fluid, but not of pus, in the blood; and he believed also that in the early stages the deposits in the various organs, as in the kidneys in one of Mr. Bullock's cases, are not pus, but fibrin. He did not think the purulent diathesis really is more common, but that more attention has lately been directed to it. It is important in the treatment that all the injured veins should be closed: he had found in most cases of secondary purulent affection that some vein remained open. He suggested a trial of the perchloride of iron for the purpose of producing coagulation, as described by M. Pravaz.

Mr. HAYNES WALTON said that secondary deposits in the brain were unfrequent; but he had met with a case in which a patient suffering from abscess of the eye had died suddenly, without pain, or other symptom of cerebral disease. A large deposit of pus was found in the left anterior lobe of the brain. No direct communication could be traced between this and the abscess in the orbit.

Mr. BULLOCK said that opium had been given in large doses in one of the cases related, but without any effect; and also chloride of lime, but perhaps at too late a period. He had endeavoured throughout to show that pus does not circulate in the veins as such: he had not detected pus-globules in the blood in any of his cases. In cases of abscess in the brain following disease of the ear, it is often very difficult to trace the connexion between the affected organs.

FORBES WINSLOW, M.D., President, in the Chair.

THE GALVANIC CAUTERY IN THE TREATMENT OF UTERINE DISEASE. BY ROBERT ELLIS, ESQ.

The earliest application of galvanism for the purpose of cauterising was made by Mr. Marshall. Mr. ELLIS's investigations had led him to a more extensive application of the remedy; and he had sought to provide for the collection and concentration of heat over a considerable surface. With this view, he used a tube of porcelain—which he had found to be the best substance for the purpose—round which was twisted about a foot of platinum wire. The porcelain is placed at one end of a silver catheter, and is connected with the conductors of a Grove's battery by means of a copper wire passing through the catheter. This instrument he believed to possess an advantage over the actual cautery in cases where it was indicated, in being always ready for use, and far less formidable in appearance.

In the application, the patient should lie on her left side. A cylindrical glass speculum is introduced, and the diseased part made to protrude through it. The mucus on the surface of the part must be removed, in order to avoid loss of heat. The platinum wire having been in a few seconds heated to a white heat, the porcelain becomes hot; and the whole is applied to the diseased part. If any portion has escaped, the cautery must be again applied. It is important that the platinum wire be raised to a white heat; otherwise it is liable to produce pain, and slight hæmorrhage from a portion of the tissue adhering and being torn away. The length of time for which it is applied should be in proportion to the extent and depth of tissue which the surgeon thinks it desirable to destroy. The pain is generally less than that produced by the application of caustic.

The after-treatment consists of absolute rest, saline draughts with hyoscyamus, and opiates if required. Warm soothing injections are also useful; and it is important that these be effectually applied. After two or three days, the patient may rise; but should still rest as much as possible. The eschar generally comes away from the eighth to the tenth day.

The cases in which this treatment is applicable are those of long standing ulceration with induration, prolapsus uteri, and in the prolapsus of the vagina and bladder described by Dr.

Golding Bird and Mr. I. B. Brown. Mr. Ellis had used it in twenty cases, without any untoward results.

Dr. MURPHY said, that Mr. Marshall and Mr. Ellis had done great service by enabling the cautery to be used in a form divested of terror to the patient. The terrible appearance of the actual cautery had given rise to the adoption of chemical means; but these had the inconvenience of spreading beyond the part intended to be acted on; whereas the power of limiting the action was an advantage possessed by the actual cautery. The employment of a porcelain cylinder for increasing the heated surface was an improvement due to Mr. Ellis.

Mr. DENDY suggested that Drs. Routh and Crisp, who had witnessed the employment of the actual cautery in cases of uterine disease by M. Jobert de Lamballe, should give an account of the cases in which he used it.

Dr. ROUTH said, that M. Jobert applied the cautery in nearly all those cases in which caustic was used by Dr. Henry Bennett: viz., in hypertrophy of the cervix, in induration with so-called ulceration, and in cancer.

Mr. RICHARDSON had been informed that Dr. Simpson of Edinburgh had used potassium as a cauterizing agent.

Mr. STREETER inquired why, if cancer of the uterus is treated with at least apparent success by cauterisation, the same remedy could not be applied to cancer in other parts of the body. He believed that many cases of uterine disease had been brought into a hard, suspicious-looking state, by the use of irritant injections; whereas warm baths, hyoscyamus, and constitutional treatment, might have cured them.

BIRMINGHAM PATHOLOGICAL SOCIETY.

THURSDAY, APRIL 14TH, 1853.

Dr. FLETCHER in the Chair.

PHLEBITIS FOLLOWING AMPUTATION. BY O. PEMBERTON, ESQ.

Mr. OLIVER PEMBERTON exhibited a specimen, showing the effects of suppurative phlebitis in the right common iliac, external iliac, and femoral veins, occurring after amputation of the thigh. The case was that of a healthy girl, aged 17, received into the General Hospital with a severe machinery accident, causing great contusion of the chest and compound fracture of the thigh, with laceration of the soft parts, and considerable hæmorrhage. The patient went on well (with the exception of slight pleuritis, which easily yielded to treatment), till the fourteenth day after the thigh had been removed; phlebitis then set in, and she died four days afterwards. The *post mortem* examination showed fracture of the cartilages of four ribs on the injured side, with inflammation and exudation of lymph on the pulmonary pleura in the corresponding situation, but without laceration of that membrane. The right lung was the seat of tubercular deposit and general consolidation, and the left healthy, with the exception of a circumscribed fibrinous deposit of old date. On tracing the large veins from the thigh upwards, they were found to be the seat of suppurative inflammation, extending to within a short distance of the vena cava, further progress being prevented by a large fibrinous clot, three quarters of an inch in length, plugging the entire calibre of the common iliac vein. Imperfect attempts at plugging were observable lower down.

A discussion then followed, chiefly having reference to the large average mortality following amputation after accidents in hospital practice, as compared with private, and especially country practice. The general opinion was, that the cause of this mortality is to be sought in the placing of a number of patients together, and their exposure to erysipelas and other miasmata, influences inseparable from hospital practice.

FIBRO-CYSTIC DISEASE OF BREAST. BY O. PEMBERTON, ESQ.

Mr. PEMBERTON exhibited a tumour of the right breast, removed by Mr. Amphlett in the General Hospital. The patient was a young married woman, aged 23, and had been a mother. She was tolerably healthy, and did not present in herself or her family any indications of the cancerous diathesis. The disease had recently progressed rapidly, the tumour having grown in a period of fourteen months from the size of a marble to that of a child's head, but having been stationary for six months of that time. It was quite painless till within a few days of its removal, and then became the seat of acute lancinating pain. It was soft in parts, and firm in others.

A section of the tumour presented large and small cavities in different parts, the chief bulk being made up to solid and dense fibrous and cellular deposit. Both the firm and soft portions exhibited under the microscope oval and fusiform cells con-

taining two or more nuclei, fibres, and free nuclei, such as are commonly seen in canceroid growths undergoing rapid development. The fibrous tissue of the gland appeared to have become occupied by, and continuous with, the diseased growth which pervaded the whole structure. The left breast was wasted and flaccid. The axillary glands were unaffected. The wound healed rapidly and well.

The question of the cancerous nature of the disease was debated, and it was considered that canceroid growths not essentially malignant may come, during a period of rapid development, to present appearances and structures closely identical with those which are characteristic of cancer.

FIBRINOUS DEGENERATION OF PLACENTA. BY J. BASSETT, ESQ.

Mr. BASSETT exhibited a placenta which was the seat of disease. There was nothing in the history of the case to throw light upon its pathology; the pregnancy was the first, and continued to the full time; the child had been dead for several days before birth, and the placenta was firmly adherent to the uterus. On its fetal surface there was an elevated hard ring extending around the insertion of the umbilical cord, at a distance of an inch and a half. This consisted of fibrinous matter, which extended into and throughout the whole structure, and which was in various stages of disintegration. The true placental structure was almost entirely absent, and was replaced by a reddish homogeneous substance, of the consistency of liver, permeated by obliterated vessels and tough bands. From the after history of the case, it was rendered probable that the condition of the placenta was the result of disease commencing in the lining membrane of the uterus, and of which the death of the child was the consequence.

ASSOCIATION INTELLIGENCE.

THE MEDICAL REFORM BILL:—DEPUTATION TO LORD ABERDEEN.

ON Thursday, May 12th, a deputation from the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION waited on Lord Aberdeen, at his official residence in Downing Street, in order to draw his attention to the measure of medical reform prepared by a committee of that body.

The deputation consisted of Sir Charles Hastings, M.D., D.C.L.; Dr. Robertson, M.D., of Northampton; Dr. Webster, of Dulwich; Mr. Nunneley, F.R.C.S., of Leeds; Mr. Noble, F.R.C.S., of Manchester; Mr. Bottomley, F.R.C.S., of Croydon; Mr. Walsh, F.R.C.S., of Worcester; Mr. Southam, M.R.C.S., of Manchester; Mr. Cartwright, M.R.C.S., of Oswestry; Mr. Bree, M.R.C.S., of Stowmarket; Mr. Stedman, M.R.C.S., of Guildford; and Mr. Hastings, barrister, Secretary to the Committee. The deputation was introduced by Earl Beauchamp, and was accompanied by Mr. Ricardo, M.P., Mr. Cowan, M.P., Dr. Barnes, Dr. Cormack, Mr. Wakley, and Mr. J. F. Clarke.

LORD ABERDEEN having expressed his desire to hear the views of the gentlemen present explained,

Sir CHARLES HASTINGS read the following statement:—

"My Lord,—We appear before you as the representatives of the Provincial Medical and Surgical Association, a society consisting of nearly 2,000 members, and instituted for the advancement of medical science. The members are chiefly physicians and surgeons residing in the provinces and in Scotland. The society has been more than twenty years in existence, and has regularly published transactions, and has maintained a journal for the dissemination of its views.

"We have had forced on our attention the incongruous and confused state of the profession, which presents a great obstacle to the advancement of medical science.

"There are no fewer than nineteen different sources from which licenses to practise can be derived, and hence arises an utter want of uniformity in professional qualification.

"This evil the Society have steadily endeavoured to remedy, and they have for twenty years been engaged in the endeavour to improve the organisation of the profession.

"They early established certain principles which should guide them in their attempts; these were

"Uniformity of qualification; equal right to practise throughout Her Majesty's dominions; and the establishment of the representative system in the formation of the governing bodies. These views have been repeatedly brought forward in petitions to Parliament, in memorials to government, and in public discussions.

"Sir G. Grey encouraged us with the hope that if any measure should be brought forward in which there was a concurrence of sentiment, government might be induced to lend assistance.

"This induced the Association, with the assistance of a barrister, Mr. Hastings, to frame a bill embodying the principles which they have so long advocated.

"This bill has received an unparalleled amount of support from the profession, both in England and Scotland, and we are able to speak of it as one which embodies, on the whole, the views of the Association, and of the profession at large. At the same time, we shall be ready to concur in any alterations that the government may think fit to introduce into it, provided they are in harmony with the principles of the bill. With this view, we requested the honour of an interview with Lord Palmerston, and on that occasion the Committee of the Association, accompanied by the Presidents of the Colleges of Physicians and Surgeons of Edinburgh, and by more than fifty members of the House of Commons, presented the bill to his lordship. Since that date, we have received a letter from the Home Office, stating his lordship's hope that a measure of medical reform may be introduced into parliament this session, and we believe that his lordship approves of the object of the present deputation.

"The bill contemplates the appointment of a Council to regulate the education of the profession, a Board of Examiners before whom every candidate for practice will have to appear, and a system of registration which will embrace all qualified practitioners.

"We now, therefore, my lord, come to submit the bill to your lordship, as the first minister of the Crown, as one eminently calculated to promote the welfare of the profession, and of the public at large. We earnestly request your lordship to enable it to pass into law during this session of parliament, in order to stop the agitation which will otherwise assuredly continue.

"We implore your lordship to put an end to the evils which must result, as every reflecting mind can perceive, from the present order of things, and to place the medical profession in a position, not only worthy of its own character, but one calculated to enable it to confer the greatest possible amount of benefit to the community at large.

"We have, in conclusion, to request your lordship that before the government introduce a measure of medical reform into parliament, they will previously allow the Committee, through their Secretary, Mr. Hastings, an opportunity to consider the bill."

Mr. WAKLEY wished to impress on Lord Aberdeen that the present moment was most favourable for the object which the deputation had in view, and that if the Government would now take up the measure, its success was certain. He had been labouring for thirty years in the cause of medical reform, and he had never seen anything approaching the present unanimity. There might be a difficulty in passing the Bill through the House of Commons at this moment, burdened as it was with business; but he trusted that Lord Aberdeen would introduce it into the House of Lords, it being a question eminently fitted for their consideration.

Mr. COWAN, M.P. for Edinburgh, expressed the strong feeling which his constituents entertained in regard to medical reform, and the warm support which they gave to the Bill of the Association.

Mr. NUNNELEY said that the medical profession were especially anxious for a system of registration which might distinguish qualified practitioners from such men as those who had been recently figuring in police reports, and who cast a slur on a profession to which they did not really belong.

LORD ABERDEEN said that he fully appreciated the importance of the Association and the objects which they had at present in view. He should be most happy to afford them every facility in his power, and, unless some unforeseen obstacles should arise, he hoped to be able to carry out their wishes.

The deputation, after thanking his lordship, then withdrew.

YORKSHIRE BRANCH.

The annual meeting of the Yorkshire Branch of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION was held at the Museum of the Yorkshire Philosophical Society, York, on Thursday, May 12th. RICHARD HEY, Esq., the President, occupied the Chair. There were also present: Edward Allen, Esq. (York); James Allen, Esq. (York); William Bannister, Esq. (Knottingley); Charles Chadwick, M.D. (Leeds); Thomas Cornhill, Esq. (Leeds); B. Dodsworth, Esq. (York); William Farnham, Esq. (Leeds); Thomas Hornby, Esq., (Harley Moor);

band, Esq., (York); Henry Jackson, Esq. (Sheffield); W. Matterson, Esq. (York); Thomas Simpson, M.D. (York); D. H. Tuke, Esq. (York); J. Watmough, M.D. (Pocklington); Caleb Williams, Esq. (York).

After some prefatory remarks by the President, W. Matterson, Esq., the Secretary read the Report of the Council.

REPORT OF THE COUNCIL.

In presenting their Annual Report, your Council have to bring before you several matters bearing more or less intimately on the interests of the profession.

The first subject, which is of paramount importance to this Association, is the long protracted question of Medical Reform. The amended draft of a bill was at the annual meeting of this Association at Oxford consigned to a Committee appointed to watch over its interests, and to make such alterations in its details as should be deemed necessary. An amended bill was published in the *Provincial Medical and Surgical Journal* of November 10th, 1852, containing some important alterations; the chief of which were, the insertion of an interpretation clause, and the introduction of a clause providing for the publication of an annual statement of accounts. An alteration has been made in the fifteenth clause, in favour of the pupils of registered practitioners, and dispensing with the provident fund.

The Committee had conferences with the different Colleges in London and Edinburgh. The Edinburgh Colleges agreed to the bill under certain very reasonable conditions. The London College of Physicians approved of it; and the Committee have reason to believe that an alteration in the bill, which would not affect its principles, nor impair its efficiency, would remove any objections which the College of Surgeons of England may have entertained. The Committee then determined, as the principles of the bill met with no opposition, and as the objections referred to matters of detail, in order to obtain an earlier solution of these difficulties, to submit it at once to Lord Palmerston. Accordingly, on the 18th of March, the Committee, accompanied by a deputation from the Scottish Colleges, by a number of medical men from all parts of the kingdom, and by several members of Parliament, waited upon Lord Palmerston, who received them with great courtesy, and held out hopes that he would bring it forward as a government measure; but his lordship, it appears, has hitherto found his hands so fully occupied, that he has not had time to take up the bill; neither is it probable, if introduced late in session, that it would pass into law. Mr. G. W. Hastings has therefore thought it best to make an effort to introduce the bill into the House of Lords; and arrangements are now being made for a deputation to wait on Lord Aberdeen on an early day.

At our last meeting, notice was taken of a new charter sought to be obtained by the College of Physicians. At Oxford, the contemplated changes met with considerable opposition; and it was determined to appoint a Committee to confer with the College of Physicians, and watch over the interests of those concerned in it. That Committee has been actively engaged; but the result has not been such as to prove satisfactory. On the 6th of April, a deputation of the Fellows of the Royal College waited on Lord Palmerston, to urge him to take such immediate steps as were necessary towards obtaining a new Charter. In reply, his lordship stated that he would give the subject his earliest attention. Dr. Todd, one of the deputation, reminded his lordship that he had been waited upon by a deputation from our Parent Association, which he said represented very accurately the feelings of the profession, and stated that the bill which the association advocated was in entire harmony with the Charter of the College.

The subject of the Income Tax, which has for some time past occupied the attention of Association, has, through late political events, rendered active exertion necessary. The different Branches have held various meetings, to which the profession generally were invited. Several petitions have been presented to the Houses of Lords and Commons against the unjust principle of taxing alike fixed and precarious incomes. At a meeting of the York members of the Council of the Branch, it was thought necessary to call a general meeting, and it was suggested that the chief towns of the Branch should petition the House of Commons against the proposed measure.

Dr. Chadwick, our worthy President, at once attended to the suggestion, and obtained the signatures of sixty of the profession in Leeds to a petition, which was presented to the House by the sitting members. The Secretary here obtained the signatures of nearly all the medical men of this city to a petition, which was presented by the city members. Though parliament has not yielded to our wishes, still this Branch has the satisfac-

tion of knowing that it has used all legitimate means to obtain a modification of this taxation, which presses so heavily on the hard-earned income of the medical man.

A Vaccination Extension Bill has been introduced into the House of Lords by Lord Lyttelton, the object of which is to eradicate small-pox by compulsory vaccination. Whilst the Council strongly feel the importance of the general diffusion of the practice of vaccination, they would contend, on so important a subject, for mature deliberation, and a more just appreciation of the services of the medical man. The Council recommend the meeting to adopt a petition to the House of Lords, through their President, against the proposed measure.

It is with unfeigned regret that the Council record the death of their old associate, and long-tried friend, Dr. Goldie. About three years since, declining health compelled him to withdraw from the Association, as well as to retire from the practice of the profession; and although he left this city, and went to reside in the neighbourhood of Sheffield, there lives in the memory of his colleagues a lively sense of his gentlemanly deportment, his unsullied integrity, and the industry and zeal with which he entered upon every undertaking which had for its object the advancement of science, the harmony and welfare of the profession, or the general improvement of the moral and social condition of his fellow-men. Those who had the privilege of his friendship, can also bear testimony to his private worth, to the kindly feelings of his nature, and the real benevolence of his heart; and they will long cherish the recollection of their friend and fellow-labourer, with feelings of sincere respect and affectionate regard.

In conclusion, your Council would wish to impress on the members of the Branch the firm maintenance of those principles for which it has hitherto contended, and to remember, that in unity of action lies our strength, and that our aim should be to adapt the profession to the progress of the times, and to elevate its status and moral standard.

RESOLUTIONS IN REFERENCE TO THE REPORT.

The following resolutions were unanimously adopted:—

It was moved by Mr. HORNBY, and seconded by Mr. HUSBAND, that the report of the Council be received and adopted.

It was moved by Dr. CHADWICK, and seconded by Dr. STEPHENSON, that a Petition in favour of the Medical Reform Bill be presented to the Houses of Lords and Commons.

It was moved by Mr. W. HEY, and seconded by Mr. JACKSON, that a Petition against the Vaccination Extension Act be presented to Parliament.

ELECTION OF OFFICERS.

It was proposed by Dr. WATMOUGH, and seconded by Mr. BYWATER, that the Meeting of the Branch for 1854, be held at Sheffield, that Mr. W. Jackson be the President Elect. W. Matterson, Esq., was re-elected Secretary.

Dr. WATMOUGH moved, and Mr. HORNBY seconded, that the following gentlemen be appointed the Council for 1853-4.

James Allen, Esq.; H. S. Belcombe, M.D.; B. Dodsworth, Esq.; R. Hey, Esq.; W. D. Husband, Esq.; W. Matterson, Esq.; T. Simpson, M.D.; Caleb Williams, Esq.—(York); C. Chadwick, M.D.; J. P. Garlick, Esq.; W. Hey, Esq.; T. P. Teale, Esq.; T. Nunneley, Esq.; S. Smith, Esq.—(Leeds); F. Branson, M.D.; M. M. de Bartolomé, M.D.; H. Jackson, Esq.; W. Jackson, Esq.; G. Reedal, Esq. (Sheffield); J. Ness, Esq. (Helmsley); T. Sandwith, M.D. (Beverley); H. Y. Whythead, M.D. (Craike).

It was moved by Mr. W. HEY, and seconded by Mr. WILLIAMS, that a vote of thanks be given to Dr. Chadwick, for his able services as President during the past year.

COMMUNICATIONS READ.

The following communications were then made:—

The PRESIDENT related a case of idiopathic gangrene.

Mr. H. JACKSON exhibited a large calculus weighing about 3 oz., which had been taken out of the bladder of a boy after death. He also read a case of traumatic tetanus successfully treated by chloroform and cannabis indica.

Mr. W. HEY, related a case of delirium tremens successfully treated by chloroform and morphia.

Dr. WATMOUGH exhibited a large polypus uteri which had been removed by ligature.

Mr. MATTERSON related a case of polypus uteri removed by excision.

Thanks to the President, for his conduct in the chair, were proposed and carried unanimously.

The members then adjourned to the Black Swan, where an excellent dinner was provided, and a pleasant evening spent under the presidency of Mr. Hey.

EDITOR'S LETTER BOX.

NEW IDEAS ON MEDICAL BENEVOLENCE, AND THE USE AND ABUSE OF MEDICAL CHARITIES.

LETTER FROM H. L. SMITH, Esq., TO THE EDITOR.

SIR,—As there is a hopeful, though perhaps not very near, prospect of medical men obtaining seats in parliament, it may not be amiss for us to habitually submit our thoughts to the test of the premises and clauses of acts of parliament. I therefore humbly submit to my honourable representatives, *in posse*, some of the improvements in the profession and to society, which may be brought about through their exertion. It may, at first sight, appear that the specimen acts now suggested, are not such as strictly belong to the medical profession; but it will soon be found that there is no question of sound social progress with which the medical profession are not, by reason and experience, better acquainted than any other class of the community; and also, that by reason of use of their faculties, they are better fitted than others to investigate causes of disorder in the body politic, and to suggest appropriate remedies.

First preamble. Whereas it appears that the ignorance and cupidity of working men induce them to take their children from the national and other schools, at the earliest possible age at which they can earn anything, and to employ them in keeping off crows, running errands, sweeping shops, etc., whereby their learning is interrupted; and whereby they are prevented from receiving the full benefit of that education which the liberality of individuals or of the nation has provided for them; and they forget, by such early removal, all they have previously learned.

Second preamble. Whereas it appears that much of the misery of mankind arises from their following employments, pursuits, trades, and professions, for which they are not physically, morally, or intellectually qualified, whereby boys are obliged to abandon the trade or employment to which they have been trained, to the great unhappiness of their friends and hindrance to themselves, etc.

Third preamble. And whereas it appears that many schoolmasters, and many medical men, having rendered most important services to the community and to the state, by the zeal, intelligence, and self-denial, which they have exercised for many years on its behalf, have been left to the care of union workhouses, or the worse and more cruel neglect of those whom they have educated or cured, etc.

Fourth preamble. And whereas there is much suffering, beggary, and pauperism, created and made by ostentatious charity in the form of lying-in hospitals, dispensaries, and other contrivances for creating a name amongst the fashionable, ignorant, and wealthy, by which the provident habits and prospective feelings of the industrious and working people are damaged and destroyed, etc.

The correctness of these preambles will be confirmed by the experience of every medical man; and if he wishes to read up for them, or cram any honourable member for a speech, he will find the material in the reports of the Committee on Education at Whitehall, or in the waiting-room of any great dispensary, where he will find shoe-makers, tailors, weavers, paint-makers, lucifer-match makers, etc., all giving evidence of this truth. He will also find them corroborated in the reports of charitable associations for schoolmasters and medical men; and for the last by inquiry into the effect of misguided charity, and the report of the commissioners on the charities of the kingdom. All of these would form the substance of the supporting speech, with special and individual examples in abundance.

Now for the clauses of an act of parliament to remedy the foregoing evils.

I. It is therefore enacted, that every working-man's child, who stays at school till he is fifteen years of age, and, by his industry and diligence, has obtained certain testimonials (to be hereafter fixed upon), shall have, say, ten pounds given to him; one-half to be applied towards his indentures, and one-half to be given him on his attaining the age of twenty-one, provided he has presented himself once a quarter to the inspector, and shows that he has properly maintained his scholastic knowledge and moral character.

II. That no boy shall be bound apprentice to any trade without a certificate from a medical man, and another from a schoolmaster, showing that he is a fit and proper person, by

his organization and capability, by his faculties and powers, for such employment; and that ten shillings shall be advanced for these certificates, two shillings to be given to each respectively, and the remaining six to be paid to a fund for the maintenance in old age of all medical men and schoolmasters; such as the proposed Benevolent College of Mr. Probert, a similar one to which is, I believe, under consideration for decayed schoolmasters.

III. That every honorary dispensary, or lying-in charity, shall forfeit £10 10s. for the aforesaid purposes, for every case, in which it can be proved that they have granted assistance to persons who could have paid for themselves; the circumstances of which shall be tried before a county court. As this, however, would happily soon extinguish and dry up their resources, and as the sum required would appear to be considerable, the duty on indentures should be continued, or if repealed, re-established, and applied to that purpose; the probability is that it would materially increase the number of apprentices, and that the fund so raised would be fully equal to the demand made upon it.

Let me now state, Mr. Editor, a very few of the advantages to society which would result from these few simple clauses:—

1. The parents would strive to keep their children at school, when they saw before them the prospect of an advanced step in life from education; which they do not at present.

2. The children would be able to reap the full benefit of all that the schools could teach them: we should become an educated people.

3. They would be brought quarterly, again and again, before the inspector or clergyman; and a more permanent attachment and connexion would be created between the laity and the schools, between church or chapel, than now exists.

4. They would feel during their adult age that they were yearly becoming responsible members of Christ's body, a knowing, loving, united temple, building for His coming glory.

5. We should have boys more suitably qualified and trained for their future respective employments, than they are now, from their earliest days.

6. The churl need not fear but that the crows will be kept off: and the shop swept: his allies and slaves will still remain in the children of the drunken, idle, and vicious, till they are all swept with one besom into one pit.

7. We should have the special detriments of particular trades, brought before the public by the medical man; and their reports, backed by an honest press and the dread of public indignation, would be attended to by the mammon worshippers and money-grubbers.

8. There would soon be a remedy found also for the glaring evils of particular trades, when chemical and medical science was once fairly directed to the subject.

9. Boys would qualify themselves, when at school, for their future pursuits; and not enter on them hap-hazard, as they do now.

10. A stimulus would be found to the formation of funds in aid of the proposed retreats for school masters, and medical men. (See prospectus of Mr. Probert's Medical College).

11. The disgraceful obloquy of many of our millionaires, who have been educated at the national expense, would be removed; for it would give them an opportunity of gratefully repairing the neglect of their first friend, the national-school master. Witness, A., of Blanque, who is said to be worth £40,000 per annum: he has forgotten B., who first polished the rough granite of which he is made. Also witness B., the mayor of Blanque, who employs three hundred men, besides women and children: his mother never paid the doctor (now old and worn out) for bringing B. into this devil's millennium.

12. Beggar making bastard charities, such as lying-in-hospitals, and honorary dispensaries, would be shown up as body and soul destroying inventions, to the horror of the jug and bottle department of gin palaces.

13. And thus would arise love for what is good, union to each other, and a perpetual and eternal connexion between the boy and the man—the school and the church—the laity and the clergy—the man here and the man hereafter—the church militant and the church triumphant.

I am, etc.,

H. L. Smith.

HOSPITAL ABUSES.

LETTER FROM J. Y. ARROWSMITH, ESQ., TO THE EDITOR.

SIR,—I have been so much pleased with your articles on the growing abuses of hospitals and dispensaries, that I am induced to offer a few words, *for your private ear only*, as to the difficulties to be encountered in carrying your valuable suggestions into effect. It is certain that in this town the present system of indiscriminate medical and surgical relief is productive of three great evils:—1st, that of injuring the juniors of the profession; 2nd, that of inflicting enormous trouble and engrossment of time on the medical officers of the infirmary and dispensary; and last, not least, that of inducing, in a great portion of the lower classes, “improvidence” and “extravagance”, and of “destroying in the bud the growth of” those feelings of independence and self-reliance, without which respectability and general well-being cannot exist. To redress the grievances of this system, I know that the medical officers of the different charities *here* do all they possibly can, and would willingly associate themselves with all their professional brethren in any practical or practicable measures that could be suggested to that end; but I fear that any appeal to the “discerning public”—that is, the whole body of subscribers, directors, governors, and trustees,—would be responded to by the imputation of interested and unworthy motives on the part of “the sufferers from the present system”. Each subscriber, if his individual opinion were asked, would readily assent to the *principle* of “vigilant supervision” and sharp discrimination between proper and improper objects of charity; but he is apt to make so many exceptions in *practice*, that his *principle* becomes in a great degree inoperative. I cannot exclude the “known subscriber” or the “clergyman” from this category. A clerical friend of mine, the other day, was on the point of withdrawing his subscription to the infirmary, because the physician of the week refused to admit a patient for whom he was interested, as “not duly qualified”. I remonstrated with him, pointed out the absurdity, to say the least of it, of what he was going to do, and he forbore. This is an example of what frequently occurs. People who fancy their name and supposed influence set at naught by the rejection of their recommendations, revenge themselves by withdrawing their subscriptions! A lady in this town, on being asked to subscribe to the dispensary, consented, on condition that her servants might be attended from that establishment. This condition was very properly refused, and the lady kept her money in her pocket. One of the rules of our lying-in charity provides that no woman whose husband earns more than ten shillings a week, unless she has a very large family, shall be allowed to avail herself of it. A lady recommended a woman whose husband was getting eighteen shillings a week, with only one child; and on the observance of the rule being insisted upon, threatened to withdraw her subscription.

I mention these things, by way of showing the difficulty of impressing upon the charity-bitten public the necessity of being more guarded and discriminative in the gratification of their humane feelings.

The plan adopted by the Destitute Sick Society of Edinburgh is no doubt admirable, and might be applied to our largest towns; but I do not at present think it could be worked out *here*. If hospital managers, persisting, in spite of all remonstrances, in the present indiscriminate system of relief, were to be called upon for remuneration by their medical officers, those managers would instantly say—“We accept your resignations, gentlemen, which we consider you have virtually tendered; we can pick our men out of a score of competitors to succeed you, who are willing to afford us their *gratuitous* services.”

“The eager canvassing for honorary medical appointments” does indeed “tend to lower the proper value of our services to the public”; still the canvassing *will go on*, and the profession, as the late Lord Castlereagh might have said, *will persist* in “turning their backs upon themselves”. But once in office, there is anything but “cringing” displayed by medical officers to directors. For instance, there is often a “little war” about wine, and diet, and expenses general and particular, out of which the medical officers always *have* and *will* come victorious, or they would resign in a body, to the great scandal of the directors, as they very well know; therefore they succumb, being aware that the same thing would happen with any other medical officers whom they might appoint. To be *in* office and *out* of office are very different things.

To illustrate the number of those who resort to hospitals and dispensaries, in proportion to the population of the places in which they are situated, you take Bath as an example. “There

is the Bath United Hospital, and there are seven other general and special dispensaries in Bath, enumerated in the medical directories. Bath only affords a specimen of that which is going on in every town and city.” This brings me to the worst thing I have to say to you. Charity, so-called, in its various phases, is the order of the day: each charity has had its generator—its Lady Bountifuls, and its champions; and none more than the medical charities. And who have been, ninety-nine times in a hundred, the generators of medical charities? A number of individuals of our own profession, who, for their self-glorification and ultimate pecuniary advantage, have so practised on the humanity and credulity of the public, as to induce it to subscribe to all sorts of specialities, with which, of course, their own names are identified. These gentlemen have initiated the creation of a philanthropic “Frankenstein”, that runs riot with a rage they may not now be able, even if willing, to control; and though they may exist in ignoble safety from the ravages of the monster they have helped to animate, the large body of their brethren are likely to be crushed and destroyed by it.

I am, etc., J. Y. ARROWSMITH.

HOSPITAL ABUSES AND HOME ADVICE GRATIS.

LETTER TO THE EDITOR.

SIR,—There is another form of gratuitous medical assistance besides those commented on, whether by yourself or your correspondents, to which I desire to call your attention. It is this:—Many physicians and surgeons are in the habit of sitting at home for a certain time of a morning, and prescribing, without fee or reward, for all and sundry who apply to them for advice. Now, the majority of the persons who take advantage of this, as I believe, not only needless, but very pernicious liberality, are much beyond the condition of poverty or necessity, and have no title in the world to any such consideration as is shown them. They are mostly in such a position, that had they not the opportunity of going to consult these over-liberal gentlemen, they would very certainly be the patients of one or other of the respectable general practitioners in their several neighbourhoods. Now, if these gratuitous advisers are so favoured by fortune as to be spared the necessity of living by their profession, how can they reconcile it with their sense of propriety, when they find themselves interfering with their brother's chance of existence, who has no such advantages as they? Charity is a good thing, when well directed; when ill-applied, as it most certainly is in the case adduced, it is at once an evil and a great injustice. Even hospitals and dispensaries for the relief of the necessitous suffering under disease, are mainly to be abetted and upheld as schools. In any other light, they are not more defensible than is the practice of the gratuitous private advice against which I inveigh, and against which I desire to secure your voice and assistance. Save as schools for the training of young men in a knowledge of disease, hospitals and dispensaries are not more defensible than would be establishments, at the public charge, in all our towns and villages for the supply of food and raiment, without fee or reward, to all and sundry who might wish to be fed, and have their nakedness covered, without an effort on their part. And this leads me to the grand fact which I think none of your correspondents have even hinted at, viz., that as every one in this great country who is truly in want, has a legal right to relief as a pauper; so, by the law of the land, he is also entitled to medical assistance, free of charge, if he be indeed sick and penniless: or wherefore have we boards of guardians and parochial and union surgeons?

I am, etc., OBSERVATOR.

May 9th.

THE UNCERTAINTIES OF AURAL SURGERY.

LETTER TO THE EDITOR.

SIR,—It appears to me that the uncertainty which exists in some branches of medicine forms one of the strongholds of quackery. Thus, hysteria, in all its various and tiresome forms; thus, imaginary ailments of every kind, constitute the bulk of cases submitted to the homœopathic, or hydropathic, or galvanic systems. The incurableness of them is a part of the disease; and, till the will of the patient be exerted, there is no hope of doing any good. A violent revulsion from, perhaps, too much medicine to sweet little globules, or from a languid couch, port wine, and a close room, to the bracing hills and cold-

water-down-the-back system, is calculated to excite, perhaps to correct, the morbid moral feelings; and accordingly we hear of remarkable cures occasionally. We scientific people know better, and denounce it as quackery. But, I must say, from my own experience, that I can excuse anybody for going to various quacks, when "the faculty" have failed to give relief. The desire for cure is so strong in the human breast, that, if I did not believe the "wise woman of Wing" to be a sorceress, I could imagine myself becoming her patient; and, by the bye, the sequel will show, I think, that she might possibly know as much about my ears as "the faculty".

But, to spare your columns, I shall proceed at once to state my case. It is soon told. I am a physician, between thirty and forty, temperate, with no family or other taint, in robust health, ride a good deal, and work hard. Ten years ago, after a journey outside a coach, in fine weather, I suddenly found myself deaf in the right ear, as if I had a cold; but it continued month after month. There never has been any pain; the Eustachian tube is clear, and the secretion natural. The right ear has never varied much; I cannot hear a watch, unless it touch the skin. The left ear for a long time continued quite perfect, but, for the last twelve months, I fear it too is beginning to fail me. Auscultation has been my delight; and the natural nervousness arising from the constant dread of deafness has, I have no doubt, acted injuriously on me. As I once said to an aurist, I would give £500, aye, £1,000, for a cure.

In 1845, I saw my first adviser, whom I shall call Mr. I, a metropolitan. I conceived a great dislike to him, from his persisting in speaking to me, and patting me on the cheek, as if I had been an old dowager. His opinion was, that it depended on disease of the nerve. His treatment was sarsaparilla, and a journey to town once a week, to have some medicated air pumped in from a machine of his, which looks very frightful when its nozzle is half way up the Eustachian tube. This part of the treatment it was impossible for me to follow out.

I next consulted a country aurist, Mr. II, a very well-informed, acute practitioner. His opinion was, that it was nervous, or rather I should call it nervic. He ordered me thirty blisters in succession, iodine and sarsaparilla, and a pill with colchicum, mercury, and hyoscymus, night and morning. The blisters took me a long time to get through with; and at length the nervous irritability produced was such that my courage failed at No. 29, and I went and saw Mr. II again, not the least improved. He reiterated his opinion, that it was disease of the nerve, as distributed on the internal ear, or perhaps dislocation of one of the small bones (!); and gave me the comforting assurance, that the other ear would follow, and that I should be quite deaf in five or six years.

For several years after this, I consulted no one; but by and by I again sought the metropolis, as a patient; this time seeing Mr. III. He looked at the external meatus, and quickly said, "Ah, I have 127 dissections of similar cases in that drawer." "By George, I don't mean you to dissect mine", was my reply; and he proceeded to inform me that my deafness depended on contraction of the osseous meatus, and thickening of the tympanum. He advised me to become a teetotaler, to apply concentrated tincture of iodine behind the ear and over the mastoid process, and to take the everlasting iodine and sarsaparilla internally. I tried the total abstinence for six weeks, with the most unpleasant results, dyspepsia, want of sleep, etc.; and the treatment, like everything else, failed to give any relief. Would you believe it? I saw my case actually reported, with a drawing illustrative of osseous contraction of the meatus; while other aurists assured me (of course I cannot see down my own ears) that nothing of the kind was there!

I next saw Mr. IV, who did not take long about his diagnosis. "Ah, all mucous membrane." I have so often quizzed patients of my own who have complained of suffering from "mucous membrane", or whose friends were ill of "mucous membrane", that it was a kind of retribution to be told I had it myself. Well, he told me I must take iodine and sarsaparilla again—oh, how I hate the taste of it—a dose of aloes twice a week, and sleep with my mouth shut! He accused me of sleeping with it open; and I have since discovered that I am an inveterate snorer. (N.B. I am a bachelor.) This treatment disordered my bowels, and by and by produced a most annoying irritation of the throat and fauces. I left it off, began it again, and all with no benefit.

I was induced to consult No. V by a memorandum I had made years before in my scrap-book. "Mr. So-and-so cures deafness by music. Pleasant." Well, he said music wouldn't do me any good, that my deafness was all a bad habit; he rubbed a little tincture (it felt like tincture of nettle-stings) on the ear,

and then insisted I was "better already"! I got some more of this said tincture, and tried it, but with no good effect; and the pain from its reaching the eye accidentally is diabolical.

Lastly, I consulted Mr. VI. I told him I had seen five aurists, and had got five different diagnoses, and five different plans of treatment; but he did not wish to hear them till he had made his examination; and he actually got a sixth diagnosis for me—"a granular condition of the meatus, and probably of the Eustachian tube". He desired me to take Plummer's pill and colchicum, to gargle my throat with an astringent, and to leave off smoking. I had told all of them that I did indulge in the weed, but he was the first who said it was noxious. I did leave it off for a month, but afterwards was obliged to resume it in moderation, as I found I could not work without it. I swallowed an immense number of those said pills—nine dozen, one every night; and here I am, not one bit better than I was: indeed, I begin to fancy that the prospect held out by Mr. II is beginning to creep over me, and the left ear to give way as well.

I do not wish to seek for prescriptions in the Journal; but if any member can help me by any suggestions, either in its pages, or privately, addressed "A. B. Surditas, M.D., office of the Association Journal, 37, Great Queen Street, Lincoln's Inn Fields", I shall direct them to be called for.

The aurists I have consulted are all "all, honourable men", some of them highly scientific, and others highly successful; but hardly two of them have agreed. This, I again assert, is the ultimate cause of quackery. Where would I not go—what would I not do—to be cured, or even to know the real state of matters? I hope none of the gentlemen whom I have consulted, if this meet their eye, can feel offended if they recognise themselves and me. They have all received me most kindly, and seemed most anxious to do me good. It is not the aural surgeons, but aural surgery, that I find fault with. I venture to say there is not another organ, the diseases or derangements of which could have such a varied nomenclature, or so many contradictory diagnoses, as the ear.

I am, etc.,

A. B. SURDITAS, M.D.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXI.

LONDON: FRIDAY EVENING, MAY 27, 1853.

NEW SERIES.

THE PROGRESS OF MEDICAL REFORM.

THE London Medical Reform Committee, the formation of which we announced in our last publication, has already placed itself in communication with Government. It has likewise resolved to appeal to the friends of medical reform, for pecuniary support. As the contributions are expected to be very numerous, the Committee do not solicit large donations.

We subjoin a copy of the memorial of the Committee. It has been sent to Lord Aberdeen, as well as to Lord Palmerston.

To the RIGHT HONOURABLE VISCOUNT PALMERSTON,
Her Majesty's Secretary of State.

MY LORD,—On behalf of a Committee appointed at a meeting of medical men, held in London on the 18th of May, 1853, to promote the passing into law of the proposed Bill for the better regulation of the Medical Profession, prepared by the Provincial Medical and Surgical Association, and presented by that body to your Lordship, we beg to submit the following statement to your notice:—

The present condition of the Medical Profession imperatively demands the immediate interference of the Legislature. And for these, amongst other reasons:

- I. The utter want of uniformity which at present exists in Professional Qualification, there being no less than *nineteen* different sources from which Licenses to Practise can be obtained.
- II. The hardship by which highly educated men are restricted in their Practice to one particular portion of the kingdom; a Practitioner who is legally qualified in England being unqualified in Scotland or Ireland, and *vice versa*.
- III. The want of a system of Registration by which men who have been properly educated, and who possess a Legal Qualification, may be distinguished from ignorant and dishonest pretenders.

We would point out to your Lordship that these evils affect the Public no less than the Profession, because they may at times deprive the sick and suffering of the best medical assistance, and because they continually place them at the mercy of uneducated and unscrupulous men. An example of the pernicious consequences that flow from the present defects in the law, is afforded by a recent case in a public Court of the Metropolis, where two individuals have been charged with the offence of criminally procuring abortion. These persons are described as medical men, and appear to have been practising as such; though there is no ground for believing that they have any legal pretensions to the title.

We are convinced that the proposed Bill prepared by the Provincial Medical and Surgical Association is a wise and salutary measure, and one well calculated to remedy the evils of which we complain. We think this, because it provides for one common examination, through which every candidate for practice must pass; because it gives to every one thus examined an equal right to practise throughout the United Kingdom; and because it establishes an efficient registration.

We know that it is supported by a very large majority of the medical profession throughout the kingdom. We know

that many petitions have already been presented, and that many more will shortly be forwarded, to Parliament in its behalf.

We have reason to believe that a considerable number of the members of the House of Commons have expressed their determination to support the measure, should it be introduced into Parliament.

We therefore consider that the present moment is eminently favourable for the settlement of a question which is of great importance to the medical profession, and to the whole community, which has been long agitated, and which will assuredly not be suffered to rest till it has been brought to a satisfactory solution.

We therefore earnestly entreat your Lordship at once to take up the question, and to pass into law the Bill now in your hands, during the present Session.

In conclusion, we may state that we are entirely unconnected with the Provincial Medical and Surgical Association, and are only desirous of the enactment of the measure above-mentioned, because we believe it to be one that will prove beneficial to the public and equitable for the whole profession.

We have the honour to remain,

Your Lordship's obedient servants,

(Signed) EDWIN LANKESTER, M.D., *Chairman.*

J. DALSTON JONES, M.D. } *Secretaries.*
W. M. POWELL.

We observe that petitions have already been presented to Parliament in favour of medical reform from the following places.

PLACES.	No.	PLACES.	No.
Edinburgh Col. of Phys.	1	Newport (Isle of Wight)	1
Edinburgh Col. of Surg.	1	Alford (Lincolnshire)	1
Worcester	1	Shrewsbury	1
Evesham	1	Doncaster	1
Guildford	1	Sheffield	1
Hull	3	Bath	1
Leeds	1	Stowmarket	1
Durham	1		
Dewsbury	1		18

While the general body of the profession are thus engaged in petitioning parliament in favour of medical reform, some of the corporations, we hear, are preparing to defend their special interests by counsel, at the bar of the Houses of Parliament. We sincerely trust that Government will grapple with, and decide those questions of competing privilege, provided no compromise between the conflicting parties can be arranged. The united voice of the profession is in favour of the immediate passing of an Act of Parliament, securing—*first*, uniformity of professional qualifications; *second*, reciprocity of privileges in the three kingdoms for qualified practitioners; and *third*, the registration of legal practitioners, so that the public may be able to distinguish them from unqualified pretenders.

All other questions of medical reform are of less urgency and more difficult; but these are so paramount and so obviously calculated to promote the honour of the profession and the safety of the public, that they must not be sacrificed at the shrine of class and corporation jealousy.

PRE-RAFFAELITISM AND MEDICAL ART.

A FEW years ago, three or four young artists, of determined character, saw, or thought they saw, that the true road to real eminence in their art lay in the conscientious study of nature. They believed that, if an artist wished to represent a tree, he must diligently set to work by copying that tree, and not by merely copying his own impression of a tree remembered in his studio, or, worse still, imitated from another master. They therefore refused to draw a line, or to use a brush, except in the presence of the object to be painted. Their canvas was secured in a box under lock and key, which was carried to the spot where the tree stood, and only used there. These "Pre-Raphaelite brethren" had to bear much adverse criticism; but the crowds now at the Royal Academy, standing before the paintings of Millais, Hunt, and C. Collins, are some evidence that these young painters were not mistaken in their principles, and that their conscientious diligence has had its reward.

There is a parallel between this and our own art at this time. There are indications that the same spirit is at work in both. A society has been formed, called the "London Medical Society of Observation", which will receive no case "unless it shall have been noted in writing at the moment of observation". To facilitate their labours, this society has published an excellent little book, with the title, "*What to observe at the Bedside, and after Death, in Medical Cases*", which has been prepared with infinite diligence, painstaking labour, and deep acquaintance with the subject, so as to be a valuable instructor to those who are commencing their profession, and an useful refresher to all in the investigation of obscure cases.* Their rule, to admit no cases not noted down at the moment, is an excellent one; and we may much doubt whether any real addition can be made to our knowledge of facts, unless such strict attention to truthful detail is scrupulously adhered to. Very few, it is true, are able to make original observations; so that the power of seeing a new fact looks like intuition, though, after all, it is probably the reward of persevering attention. The majority of us are compelled to be content with seeing what has been discovered for us. We go to Laennec, to Louis, to Bright, to Brodie; and when they have taught us what is to be expected, we can determine whether it is so in the actual case before us. But for those who would advance our knowledge, who hope to be discoverers themselves, there is no short road, nothing available but the most painstaking and laborious attention: and all such should follow this good rule of noting at the time.

The *soubriquet* given to these artists may also teach us something. They are called "Pre-Raphaelites", from their belief that painters of faces are too apt to copy not nature, but Raphael's idealisms; and that there was more truth in art before this great man's time, as artists then went to Nature herself. Some affectation has been grafted on this; but the lesson to be drawn is, that those who write on medical matters must go to Nature, and not to books. We are deluged with second-hand descriptions of well-known diseases, or at least of well-known descriptions of diseases. What we want is, that men who write should observe Nature with their own eyes, and describe it; and not write from their memory of books, like the painters from their remembrance of Raphael. How common is the remark, that when we consult a book for a difficult case, it throws no light on it; and this is not certainly from the want of books; they

are as abundant almost as disease. But men go on, often unconsciously, copying the old masters, and thus accumulate words without real matter. True reputation in medical science is only possible in these days to well-directed labour in observing and reflecting on disease; and we trust this new school of medical observation will turn out true discoverers; men not merely content with the reputation of successful practice, but whose fame rests on a deeper basis—their original insight into the laws of health, and disease, and cure.

HER MAJESTY'S ACCOUCHEMENT: CHLOROFORM.

ON the 15th of April, we announced to the profession that chloroform had, on the 7th of that month, been administered to the Queen, under the sanction of Her Majesty's Physician in ordinary, Sir James Clark, Her Majesty's First Physician Accoucheur, Dr. Locock, and Her Majesty's other Physician Accoucheur, Dr. Ferguson.

On the 14th of May, that is, after one month's silence, the *Lancet* said—

"Intense astonishment has been excited throughout the profession by the rumour that Her Majesty during her last labour was placed under the influence of chloroform, an agent which has unquestionably caused instantaneous death in a considerable number of cases. * * * Probably some officious meddlers about the Court so far overruled Her Majesty's responsible advisers, as to lead to the pretence of administering chloroform; but we believe the obstetric physicians to whose ability the safety of our illustrious Queen is confided do not sanction the use of chloroform in natural labour."

As the article in the *Lancet* is calculated to throw discredit upon our statement, we think it right to repeat it, along with an assurance of its accuracy. The expressions which we used were as follows:—

"We understand that chloroform was administered by Dr. Snow during the latter part of the labour, with very satisfactory effect; and that the Queen expressed herself as grateful for the discovery of this means of alleviating and preventing pain."

The *Medical Times* of May 21st, in reply to the *Lancet* of the 14th, repeats and enlarges our statement in the following words:—

"Dr. Snow administered chloroform to the Queen, in the presence of Sir James Clark, for the last hour of parturition. A handkerchief, on which a small quantity of chloroform had been dropped, was held to the face. Her Majesty was never completely insensible; but she expressed herself as satisfied with the anodyne effects produced. Should further information be required, we are confident that Dr. Snow will, with his usual courtesy, afford it to all such as consider themselves entitled to ask it."

We did not venture to make our original announcement upon mere rumour; and we now, upon the best authority, inform our readers, that our statement, and that of the *Medical Times*, are correct. We therefore repeat, that the recent accouchement of Her Majesty was an "event of medical importance", and "calculated to remove much of the lingering professional and popular prejudice against the use of anæsthesia in midwifery". We would remind the *Lancet* that anæsthesia may be induced without loss of consciousness. To those accoucheurs who are in the habit of using chloroform in labour, we would refer, for final decision, the question of its being a safe or a dangerous practice. From a careful perusal of most of that which has been written on the subject, as well as from some personal experience of the practice, we may in the meantime state, as our own humble opinion, that the cautious inhalation of the vapour of chloroform during labour is entirely free from danger, and calculated to afford merciful relief from pain, in one of the most agonizing trials of humanity.

* Vide ASSOCIATION MEDICAL JOURNAL for January 14th, p. 89.

ORIGINAL COMMUNICATIONS.

ILLUSTRATIONS OF TUBERCLE.

By EDWARD HENRY SIEVEKING, M.D., Fellow of the Royal College of Physicians, Assistant Physician to St. Mary's Hospital, etc.

(Read before the Harveian Society of London, April 7th, 1853.)*

THE term tubercle is synonymous, as we all know, with nodule, and does not in itself imply any peculiar constituents. Usage has, however, limited the application of the denomination to a certain form of deposit, which we meet with but too frequently in the cadaveric inspections which we are allowed to make, and which, at all ages of life, is a source of danger to the individual, and of serious consideration to the medical practitioner. There is no necessity for urging the importance of the subject; but it is sometimes useful to bring a familiar fact before our eyes in a form in which we are not in the habit of seeing it. Thus, we find, with regard to the frequency of tubercular disease, by striking an average of ten weeks taken at random in the Registrar-General's Report for 1851, that it ranks second in mortality of all the causes which the returns specify. Zymotic diseases stand first; tubercular maladies follow in their wake; diseases of the lungs and of the brain respectively occupy the third and fourth position. The exact numbers for the ten weeks are as follows:—

Mortality from zymotic diseases,	19,914
" " tubercular diseases,	18,395
" " cerebral diseases,	12,068
" " pulmonary diseases,	15,475

But we all know that individuals are frequently carried off by diseases to which a name is applied that does not indicate any tubercular affection; while the scalpel exhibits to us lesions sufficiently indicative of tubercle having been sown, or of such a taint having existed in the circulating fluid as to produce that peculiar debilitating effect which renders treatment ineffectual, which, under more favourable circumstances, might have saved the patient. So far, then, from diminishing the Registrar-General's ratio, or rather the ratio indicated by his figures, we would enforce the earnest lesson they teach still further, by pointing to the numerous cases included under other headings, which, though not bearing the stamp of tubercle so prominently, yet do present it, and therefore deserve to be classed with the second department.

That constitutional tendency which leads to the deposit of tubercle, and is to be found wherever the necessary stimuli of life, and, above all, pure atmospheric air, are deficient, predisposes to other diseases as well; it assists the approaches of the enemy, and actually places the fortress in his power before a formal assault is made. Though we no longer believe in the elements of Thales, we may, without a great stretch of the laws of the natural sciences, admit that air is the chief element of health or disease, according as it is supplied to the lungs in its unadulterated condition of four-fifths nitrogen and one-fifth oxygen, or as it carries diffused through it carbonic acid gas, carbonated hydrogen, sulphuretted hydrogen, the effluvia of cesspools and drains, the poison of influenza or cholera, the emanations of the variolous or typhous patient. As long as it was supposed possible that the royal hand could charm away by its mere touch the accumulated effects of long neglect of Divine laws, and crowds of scrofulous subjects thronged the path of royalty in order to be saved from their loathsome disease, neither could the patient be relieved, nor the dignity of the healing art be vindicated. But, though the darkness that spread over the human mind has been somewhat lightened, and though we may have penetrated be-

yond the first barriers of knowledge, so as to obtain a glimmer of the goal for which we have to struggle, we are yet far from having reduced the various forms of diseased action to such definite laws that we may arrange them as a science, and rest contented with the contemplation of the edifice which our predecessors and our contemporaries have erected. There is much which we may yet learn from the fathers of medicine, in regard to the patient and careful analysis of disease; but we possess this undoubted advantage over them, that, in the means of analysis, in the aid afforded by chemistry and the microscope, we may approach nearer to the elements of vital action, whether in its normal or in its perverted state, than they were able to do. Still, even here we must not blind ourselves to the fact, that we have scarcely reached beyond the elements, not of diseased action, but of the products of diseased action; and not even have we succeeded in displaying the primary effects of morbid action, but all we can assert as having been achieved is the investigation of its secondary products. Hewson and Gulliver, Christison, Bright, Andral, Frerichs, Garrod, and many others whose names are familiar to you by their researches into the constitution of the blood in disease, have earnestly laboured to grasp their primary effects. Their light shines on our path, and will illumine the tottering steps of future inquirers; but beyond a faint indication of what is to be done, we can scarcely admit a great approach to what lies before us; and we are perhaps constrained to admit that we shall not understand the relation of secondary effects until we have a greater insight into the first changes constituting disease. Yet we have no alternative but to proceed rigidly in our analytical inquiry, holding strictly to the legitimate mode of research, and eschewing all hypothesis for which we have not the guarantee of scientific induction.

The questions which suggest themselves for solution, in regard to any morbid growth, apply equally to the subject of tubercle. They affect the origin, the mode and situation, and the ultimate constituents and character, of the deposit. Each of these involves subjects for further consideration, not the least of which is the medical treatment. It is, however, manifest, that, until we have a definite understanding of the points first alluded to, our therapeutic proceedings will be conducted in the dark. They may be occasionally successful, but they will be altogether empirical; and we shall derive little intellectual profit or gratification from our profession. A knowledge of the precise locality in which tubercle is deposited will necessarily aid us in determining whether and how we can attack it locally; a correct appreciation of its ultimate elements will enable us to choose the remedies which may affect the product, or diminish the constitutional tendency in the most secure and legitimate manner. If our studies show us that in many instances the product of the tubercular cachexia is beyond the reach of curative agents, we may at least hope to discover the laws regulating its introduction into the system, an acquaintance with which will enable us to avoid those causes which induce the constitutional taint.

Allow me, then, briefly to advert to the origin of tubercle. We possess sufficient evidence to show that it is derived from the blood; that it transudes from the capillary vessels of the part in which we find it; and that, after having been deposited, it is liable to undergo certain further changes. On a close examination of incipient tubercular deposit, we may always note that there is congestion in the tissues immediately surrounding it. In the pia mater of the Sylvian fissure, we see an increased redness, in which a few vessels are more prominent than usual; in the pulmonary parenchyma we may, especially by the use of the microscope, discover the engorgement of the interlobular capillaries investing the air vesicle into which the tubercle is being secreted; in the mucous membrane of the intestines, we see the exquisite arborescent arrangement of the congested vessels, tending from the mesenteric attachment to the point where we observe the deposit shining through the mucous surface from the submucous tissue, in which it has collected. The first elimination of the morbid

* The paper was accompanied by a large number of illustrative drawings, of which we are necessarily precluded from giving the readers of the ASSOCIATION JOURNAL more than seem essential to explain the author's meaning.

product acts like a magnetic point of attraction, and generally serves as a centre round which the deposit progressively enlarges by eccentric deposition. The amount of vascular action accompanying the elimination varies in different individuals; in some, there is scarcely a perceptible increase in the sanguineous current; in others, we cannot deny the presence of acute inflammation, shown both by the congested state of the blood-vessels, and by the presence of plastic exudation and exudation corpuscles. In ordinary inflammatory conditions, we may actually observe the part taken by the capillary vessels in the process of transudation. We see the inflammatory product immediately after its passage through the vascular membrane, coating the vessels; and, if my limited observations justify the statement, we may see the same matter within the vessels, adhering to the coats, previous to its discharge. Whether it be so or not, whether we may be enabled to observe the transition of the contents of the vessels into the surrounding parts or not, it is evident that we ought not to be satisfied with ascertaining the fact of the exudation as the primary change: we are driven to take one step more, before we gain the fountain-head of the malady; we therefore look to the constitution of the blood itself in tubercular disease, in order to ascertain whether any deficiency in the normal components, any variation in their relative amount, any new products, are to be met with, which may explain the source of the extravascular deposit. All observers, who have brought either the microscope or chemical analysis to bear on this subject, are agreed that there is an alteration in the blood, indicating a want of vigour and tone. There is a general increase in the fluid parts, the water and albuminous constituents; while the solids are diminished, the fibrine and the red corpuscles are reduced in quantity, and both exhibit what has been termed a diminished vitality; the fibrine possesses less plasticity; the blood corpuscles are feebly formed, their outline less defined, their colour faint, and the colouring matter easily yielded up to the surrounding fluid. The actual relation of the white cell to the red corpuscle in various diseases has not as yet been satisfactorily demonstrated; but we are inclined to view an excessive development of the former as indicative of debility, and an aplastic, if not cacoplasic, condition of the blood: we certainly have noted an increase in their number in persons affected with tubercle. Many of the peculiarities in the blood of tuberculous individuals are also met with in the blood of individuals labouring under other diseases. We are not, therefore, justified in laying down any absolute indications which are conclusive evidence of the tubercular infection; and if we are unable to define the specific constitution of the blood that accompanies tuberculosis, it follows, *a fortiori*, that we are not possessed of the means of predicating a mere tendency to tubercular deposit from the constitution of the blood. This, however, is the point at which we must hope to arrive, if, as we believe, one of the primary elements of the malady is traceable to the blood, and the seeds of the disease are sown, and must therefore be destroyed here, unless they be anticipated before their introduction into the body. On this point, Mr. Ancell, in his laborious work on "Tuberculosis", judiciously remarks:—"The predisposition differs from the general disease only in degree, and the condition of the blood in the predisposition is the same, differing only in degree"; and so undoubtedly it is, but we yet want that positive and conclusive sign by which the predisposition may be recognized by analysis of the blood. It is manifest that, with regard to tuberculosis as well as other diseases, such an indication would be of extreme value; for, as the diagnosis of morbid processes in the thorax has improved, our treatment of these diseases has commensurately acquired greater simplicity and greater certainty. In the same way, it is tolerably certain that, if we discovered the means of recognizing the seeds of a malady before they had taken firm hold upon the system, we should be enabled to eradicate them, or to counteract their influence more effectively than we now can.

It is not my object at present to examine all the dietetic and regiminal circumstances which are daily forced upon

our notice in connexion with tubercular disease; but I must advert to one point bearing upon the question of its origin, before proceeding to the second division of the subject. It refers to the organ by which the malady is introduced into the system. Are we to lay the chief fault to the perspiratory apparatus of the surface, to the organ of oxygenation and purification, or to the digestive and blood-making apparatus? I need not point out to you how each of these affect the constitution of the blood by overcharging it, positively or negatively; that is, by conveying into it material in excess, or by allowing material to accumulate which ought to be eliminated from the system. Formerly, the *corpus delicti* was invariably the stomach; now, popular prejudice is directed chiefly against the lungs: and, though I am not desirous to deprive the former of its just claims to power and influence, I confess myself to be one of those who attribute in the production of the tubercular disease a greater share to the organs of oxygenation than to those of sanguification. Baudelocque, who has written some of the wisest remarks on the relation between the respiratory function and tuberculosis that I have met with, affords some very striking illustrations of this position. He states as the result of his examinations and experience, that a truly scrofulous disease is invariably caused by vitiated air, and that it is not always necessary that there should have been a prolonged stay in such an atmosphere. Often a few hours each day may suffice, and it is thus that patients may live in the most healthy country, pass the greater part of the day in the open air and yet become scrofulous, because they sleep in a confined place where the atmosphere has not been renewed. M. Baudelocque illustrates these observations by numerous well chosen instances; he refers, among others to the shepherds of his country, who may become scrofulous although they lead an open air life; but although, as he says, the disease with them is attributed to exposure to storms, to atmospheric vicissitudes, and to humidity, attention has not been paid to the circumstance that they pass the night in a confined hut, which they transport from place to place, and which protects them from the rain; this hut has only a small door which is closed when they enter, and also remains closed during the day; six or eight hours passed daily in vitiated air, which is never renewed, is the true cause of their malady. I have spoken of the bad habit of sleeping with the head under the clothes, and the insalubrity of schoolrooms, in which a number of children are assembled together. The repetition of these circumstances is often a sufficient cause of scrofula, though they may last but for a few hours a day. Human beings and animals are equally affected by vitiated air: close rooms, as Dr. Arnott has pithily remarked, act like extinguishers to the vital flame; and the extinction literally takes place at the point at which the fuel accumulates for want of being burnt off. If space and time allowed, I would multiply the evidence that has been adduced in support of the particular view which I have dilated upon; but this is beyond the limits of this paper, and moreover, there is now scarcely a necessity for enforcing what, I believe, is the prevailing opinion among medical men. To sum up, while we would not deny which defective supply of food and raiment influences the production of tubercular disease, no cause so certainly predisposes to and generates it as defective aeration. The exact part taken by the *light* in this matter cannot be appreciated. Its direct influence upon the health of everything living is proved irrefragably; but whether its absence can alone induce morbid states of a definite character, remains yet to be proved.

As the tubercular deposit is derived from the blood, it is not surprising that all the organs of the body are more or less liable to become the seat of the morbid product. Some tissues present a greater proclivity to the elimination than others; and some, as the fibrous and tegumentary tissues, appear to enjoy almost an immunity from tubercle. At the two ends of the scale, we may place the mucous membranes and the fibrous tissues: the former are the true soil for the tree of death; the latter are rarely, if ever, affected. There can be little doubt that this depends in a measure upon

certain physical laws, influencing the current in the vascular system, and determining the greater or less facility of transudation, in the first instance. I should venture to suggest, that we may lay it down as a law regulating the deposit of tubercle, that it is effected at that point of an organ or of a tissue where the smallest amount of pressure is exerted upon the capillary system. This does not exclude the operation of other laws, which determine the attraction to any one organ. It does not offer any reason why in one case we find tubercle in the spleen, in another in the mesenteric or bronchial glands, in a third exclusively in the pulmonary tissues; but it seems to embrace the various circumstances modifying the exact site of the deposit in these different parts of the system. The *vis a tergo* varies but little in the different parts of the capillary system; but the relation to surrounding tissues differs very much. Thus, while the force with which the blood is driven into the nutrient artery of the sternum, and into the interlobular plexuses of the lungs, is identical, the pressure which the respective capillary systems meet with in a case of congestion, which implies a tendency to exudation, is necessarily greater in the bone than in the soft parenchymatous structure. No organ is more frequently the seat of tubercular deposit than the lungs, and in none do we find the capillary ramifications of the vessels with so little covering. They almost lie naked on the surface. Beyond the basement membrane forming the air vesicles, and possibly a delicate epithelial layer, there is nothing between the capillary network and the atmosphere. We need not therefore wonder that the ultimate vesicle in which the bronchule terminates is, above all other points, that of tubercular election. The receptacle is ready; the product being in the blood, a slight increase of pressure will overbalance the natural and healthy equilibrium between the external and the internal fluids, and the discharge takes place. If our view is correct, nothing but a previous change in the ultimate vesicles or bronchules could give rise to a deposit of tubercular matter in the intervesicular tissue, in the parenchyma of the lung itself, as contradistinguished from the respiratory cavities. We can suppose that obliteration of a portion of the breathing apparatus might leave the intervesicular texture less resistant than the air vesicles; and in that case we should expect to find an interstitial deposit. Whether this does actually occur I am not prepared to say. I have not seen any appearances that would justify the assumption of a primary interstitial deposit, but I have seen a distinct deposit of tubercular matter within the air-vesicles, and I have traced its primary deposit, in the semi-liquid form, in the solitary vesicle, to the deposit in numerous adjoining vessels, causing destruction of their breathing power and obliteration of the bronchule terminating in them. There is some difficulty connected with these investigations, which I may point out to those members who are not in the constant habit of employing the microscope. The air-bubbles issuing from the pulmonary tissues that have not been entirely obliterated, are very liable to obscure the field of vision, and to prevent our observations; while, when the entire obliteration by which all air is expelled has taken place, the parts are rendered so opaque, that it is next to impossible to obtain sufficiently delicate sections to show the specimens clearly. It is only by frequent examinations, and by carefully watching our opportunities, that we can succeed in obtaining well defined specimens. I may take this opportunity of remarking, that in the drawings I have added nothing from my imagination. They are as accurate representations of nature as my abilities allowed me to give; but as they were all taken with the object before me, whether viewed with the naked eye or with the microscope, I pledge myself for their truthfulness, so far as I can answer for my eye and my hand.

Before proceeding, I may be allowed to advert to the drawings, so far as they illustrate the remarks which I have hitherto ventured to offer to you. The most marked evidence of the congestion surrounding recent tubercular deposit is given in drawing 15c (Fig. 1). The blood being more persistent in the vessels than in a healthy lung, I

succeeded in obtaining distinct views of the loops encircling, as you will perceive, the ultimate air-vesicles. I next refer you to figure No. 91a (Fig. 2), to show how the

Fig. 1. A single milary tubercle, semiopaque, surrounded by highly injected blood-vessels. Mag. 20 diameters.
Fig. 2. Semiopaque milary tubercle, deposited throughout both lungs of a child, aged 5 years, a patient of Dr. Markham's. The tubercular matter distends the ultimate air-vesicle, the basement membrane of which is clearly defined. The ultimate bronchule is perfectly free and patulous. The tubercular matter fills the vesicle as a bullet fills its mould. Mag. 40 diameters.

effusion of tubercular matter takes place into the ultimate air-vesicle, causing it in the first instance to assume a globular form, and entirely impeding any interchange between

Fig. 3. Recent milary tubercle, also showing the deposit within the ultimate air-vesicle and the bronchule leading to it, the latter as yet patulous. The tubercular matter is surrounded by a dark ring of exudation corpuscles. From a man aged 60, a patient of Dr. T. K. Chambers, who had been ill six weeks. Mag. 40 diameters.

but that its presence is now considered certain proof of an

Fig. 4. Grey milary tubercle, to show the limitation of the deposit within the air-vesicles and the exudation surrounding the former. From a patient of Dr. Sieveking, a man aged 27. There was extensive tubercular deposit and intense congestion surrounding it, in both lungs; this has not been represented in the cut.

inflammatory process. I may remark parenthetically, that while we rarely, if ever, meet with an inflammatory condition of the lungs and brain, in which this microscopic sign is absent, it much more rarely occurs in other organs and tissues, as in the kidneys or liver, in the pericardium or abdominal mucous or serous coats. Drawing No. 25 (Fig. 5) affords

Fig. 5 shows the more advanced stage of tubercular deposit. The air-vesicles are closely aggregated together, but the pressure is not yet sufficient to destroy their general circular form. Some melanotic matter is seen scattered upon them. Taken from a female patient of Dr. Weber's. Mag. 60 diam.

another instance, on a larger scale, of the deposit of tubercle within the respiratory cavities. Here, too, the deposit scarcely having consolidated, the pressure has not affected these vesicles universally in such a manner as to cause the circular outline to be destroyed. Of this effect of increased pressure, No. 32 (Fig. 6) affords demonstrative proof. Here you

Fig. 6. Crude yellow tubercle; the circular form of the vesicles is destroyed by the mutual pressure exerted in consequence of the advance of the deposit; the bronchule leading to the cluster is obliterated, and converted into a mere ligamentous band. Mag. 60 diam. The specimen is taken from a patient of Dr. Markham's.

observe the vesicles presenting a honeycombed appearance, with an almost uniformly hexagonal outline, in perfect accordance with the physical laws which you are familiar with. The bronchule, you perceive, leading to this obliterated portion of lung-tissue, is in each instance equally rendered impervious, and the tubule that ought to be patulous, to permit the passage of the vivifying stimulus of air, is choked up, fine-drawn, converted into a blind alley. Observe, too, in this case, the utter obliteration of the interstitial tissue, which, in No. 91 (Figs. 2, 3), is seen to intervene between the vesicles containing the tubercular matter. These illustrations offer nothing new, and nothing unexpected; and yet we seem to feel a surprise that a disease should produce so palpable and mechanical a change in the most vital organs, and that our means to arrest and destroy it should amount as yet to so very little.

The law to which we have adverted as, in our opinion, regulating the deposit of tubercle, viz., that the tendency to the deposit in any organ is inversely as the pressure the vessels sustain, or that it is in the ratio of the laxity of the tissues, is supported by the views which are commonly held with regard to the chemical constitution of tubercle, by the form and mode of deposit in the various organs of the body, and it also assists us in explaining why certain parts of different organs possess so marked a liability to become the seat of tubercular exudation. This feature constitutes an essential difference between tubercle as a mere effusion of

a certain constituent of the blood, and those other new formations in which we cannot but see a tendency to independent development or organisation. The most familiar instance of pathological processes with which I would compare it, are the serous effusions that take place into the peritoneal cavity, from obstruction to the vena cava or portal system, inducing congestion and consequent liquid discharge at the most yielding points. If we adopt the view suggested, it appears to me to offer an explanation of the circumstance that the apices of both lungs are the chief seats of tubercle, while it tends to show the importance of encouraging the use of all the physical means at our command to promote a free and active circulation of the entire vascular current, and to obviate and anticipate anything approaching to local congestion in the organs and parts of organs which we know to be most liable, at different periods of life, and under different circumstances, to become affected with the disease in question. The manner in which I would apply the law to the explanation of the predominant proclivity of the pulmonary apices, is simply this: the upper portions of both lungs are surrounded by more unyielding parietes than the inferior; they have less room for expansion; consequently, if there is any increase in the vascular current supplying these parts, the difference between the pressure of the parietes and of the atmosphere within the vesicles will increase unduly, and effusion will take place into the latter. In acute tuberculosis, we do not observe this peculiar election, because the process is of a more active character; the strain upon the capillaries of the entire organ is greater than they can bear, and we consequently find the deposit takes place with much uniformity throughout the lung. In the chronic forms in which tubercular deposit generally occurs, the balance of the forces in the different parts of the vascular system is in a measure preserved, and only the very weak points are assailed. We do not at all deny that other forces come into play, and that there are elective affinities between different tissues and morbid products with which we are not even acquainted as yet; but it appears that the circumstance alluded to is one of considerable importance in its bearings upon tubercle, both in the lungs and in the brain and abdominal tissues. To take a single instance from the latter: in scrofulous deposit in the kidneys, where does the tubercular matter invariably present itself? In the loose textures of the cortical substance. The dense tubular tissue, with its stronger basement membrane and firmer epithelial coat, wards off the encroachment; but the feebler texture of the convoluted tubes is unable to repel the enemy.

Allow me now finally to examine shortly the ultimate constituents of tubercular deposit, to see partly whether it exhibits characters by which we may surely recognise it, and partly whether it offers, as far as our present knowledge goes, such features as to destroy all fair ground for hope that we may succeed in curing or eradicating it from the system. Perhaps I ought to have apologised to you for the method which I have pursued in the consideration of the subject; but I have followed the same mode of explaining to you my views, as I have followed in arriving at them myself. The ruder and more general characters of disease, and their relation to physiological states, are those which first attract our attention; from their examination we proceed to the contemplation of the more recondite phenomena of disease; and thus, by truthful observation and rigid inductive analysis, may hope to arrive at the real laws which govern the most wonderful fabric of the human body.

The simplest definition of tubercle appears to me to be, according to the present state of knowledge, the following: *Tubercle is an exudation from the blood of a protein compound, incapable of organisation, but undergoing certain physical changes independent of vital influences.* Tubercle is, in fact, effete matter which the powers of the system are unable to use as building material to repair the natural waste; and it is deposited in this or that organ of the body according as it is invited by the greater or less liability of the part. Tubercle is not a plastic material; it does not grow; it is not the manifestation of a departed vitality.

ating power, superadded, as it were, upon the normal energies of the system, or taking their place, such as we find to be the character of malignant disease; nor, on the other hand, is it identical with the effusions of blood-constituents which result from an exaltation of the normal energies, and continue in possession of their vitality, by which they are susceptible of organisation. This we do not see in tubercular deposit, which must be viewed as bearing to the diathesis giving rise to it, very nearly the same relation as, to use the strongest comparison that suggests itself to us, calculus in the bladder bears to the calculous diathesis to which it is due. There is, unfortunately, no such emunctory for the effete protein compounds, as there is for the excess of saline constituents of the blood; or tubercle might accumulate as the latter do, at a given point, and the product be removed by operative proceedings, or by chemical solution. The lungs and the skin have this duty to perform; but I need not stop to point out to you why we have not yet succeeded in destroying the tubercular product in the former, and removing it from them, by direct applications. I do not myself despair of a remedy being discovered which, in a gaseous form, may be conveyed to the deposit in the lungs, and, by dissolving it, enable the patient to expectorate it; but this would only affect a single organ. The cachexia leading to the local product will ever remain the real malady to deal with, so that we may anticipate its local effects.

The changes which take place in the deposit itself, and which have been the source of much discussion, and of some very wild speculations, are, as I have already observed, closely allied to what we see taking place out of the human body in inorganic substances. They seem to follow the laws regulating crystallization and chemical decomposition rather than those of vital action.

The earliest form in which tubercle presents itself to the eye is that of a faintly granular blastema, in which we are only just able to trace a tendency to aggregation into circular forms. An instance of this is given in the microscopic view of the miliary tubercle represented in drawing No. 91a, which was taken from a case of acute tuberculosis occurring in a patient of Dr. Markham's, secondary to rheumatic disease of the heart, and central softening of the brain. Here, as elsewhere, while the process of deposition continued, the vicinity of the tubercular matter was surrounded by exudation corpuscles, with or without an enveloping wall. The next form which we find tubercle presenting is that of more definite corpuscles; they offer an oval form, with a more or less sharp outline, and a granular surface. These corpuscles are surrounded by the granular blastema before mentioned, which now becomes more definitely marked, and by and bye appears to eliminate oil-globules in a greater or less quantity. The tubercular corpuscle does not present a nucleus as its normal constituent; it is, in fact, regarded by some, among whom I may be allowed to mention your excellent secretary Dr. H. Jones, as itself a nucleus. We occasionally find cells with nuclei in tubercular matter, as you will observe in several of the drawings which I send round, but I am inclined to think that they are generally, if not always, derived from the normal tissues of the organs in which the deposit has taken place. In many cases the corpuscles offer no distinct cell-wall, but appear merely to be an aggregation of the granular blastema; and at all times the envelope presents but a faint outline, compared to the sharp and well-marked margin which we discover in the cancer or epithelium cell. In examining tubercle taken from different organs, we must never forget that an admixture of the cells and corpuscles belonging to the healthy tissues may take place, which, at first sight, gives an appearance to the microscopic field different from that described. Another source of difficulty, also, consists in the admixture of the products of secondary inflammation, which is often excited by the tubercle acting as a foreign body. In the former case, our knowledge of the healthy tissues must guide us; in the latter, we must carefully discriminate blood-corpuscles, pus, or debris of the tissues, from the tubercular deposit. In the instance of tuberculated kidney which I submit, you will see that

renal cells are mixed up with the true tubercular matter; in the glands the normal corpuscles often closely resemble the tubercular, and some care is necessary to distinguish the two. The characters which I have laid down will generally suffice to determine the question; and we may also bear in mind, that while in normal components there is generally more definiteness of outline and uniformity of shape and size, the elements of morbid products are characterised by an absence of that typical regularity. The dimension of the tubercular corpuscle generally fluctuates from one to three five-thousandths of an inch.

A term has of late been brought into vogue by the authority of great names, to which, before concluding this brief sketch, it is necessary that I should allude, as the subject to which it refers is closely associated with tubercular disease. I refer to *fibrinous deposits*. Many of the cases which are thus denominated present no differences perceptible, either to the naked eye or under the microscope, by which we can distinguish the product from tubercle; and in such it is scarcely in accordance with sound induction to assume a different disease, until we are able to demonstrate a distinct primary lesion in the blood. It is not my intention to enter fully into this very important question at present, because I should fear to exceed the limits of your patience; but I wish to point out that, while there is a wide distinction between the two forms of disease in their well marked characters, they occasionally merge into one another, and are associated together. In drawing 104, I have represented the most marked instance of a combination of tubercle and fibrine which I have met with. You perceive that the characters of each are maintained as shown in the microscopic view; while, at the same time, the naked eye appearance of the morbid product corresponds with those of ordinary tubercle. When we remember the close approach between the elementary composition of fibrine and albumen, it is only surprising that the morbid products which are formed from them should present on the whole the broad distinctions that we recognize. Here, as elsewhere, we must look further back than to the mere local deposit: the primary cause resides in the perverted impulse given to the system; that impulse itself we shall never be able to seize with physical means, but we may hope to obtain an insight, a sensual appreciation of its manifestations at an earlier period than has yet been vouchsafed to us. When we do this, we may hope to be more successful in applying our curative agents; till then we shall see but as through a glass darkly, and our steps will be, like those of the infant learning to walk, insecure and infirm.

I cannot take my leave of you without apologising for attempting to touch upon a subject of such vast importance as that of tubercle in so cursory a manner. No one is more conscious than I am myself of the very imperfect manner in which the little that has been said has been brought before you. And though I may have failed to suggest anything which your own observations and researches have not already made out, I may succeed in eliciting the observations of other inquirers into this field of pathology, which will deserve the attention of the learned members of this Society.

May 1853.

ON REVACCINATION.

By J. A. HINGESTON, Esq.

Of those who have been once properly vaccinated, an indeterminate number become again susceptible of vaccination at a subsequent but indeterminate period of their lives. It is said that this susceptibility never occurs within six months after an effective primary vaccination; and this interval of protection has been extended to seven or even ten years; but there are no proofs to warrant our implicit confidence in this assertion. The scar of a genuine vesicle is no evidence of insusceptibility; for those without a scar will remain insusceptible both of the small-pox and revaccination all their days; while others, with a scar of

normal character, will take the small-pox or revaccination, notwithstanding this apparent testimony in their favour, and contrary to our most sanguine expectations of their security. Some vaccinators say, that about half the number of those vaccinated are susceptible of a revaccination; but this computation, though it may depend on statistical calculations, gives no assurance of its positive accuracy; for, out of this susceptible half, there may be justly reckoned a great many who have been imperfectly vaccinated at the beginning, and therefore have never been thoroughly protected at any moment from the first.

The question has arisen, Whether the protective agency of vaccination does not wear out with age? Perhaps this is the most popular notion entertained upon the subject; but it is, nevertheless, an entirely gratuitous one. There is nothing to prove that this is the case. It has been proposed to repeat vaccination every seven years in each individual; but this, like the foregoing opinion, is taken for granted, and nothing actually certain is ever pretended to be advanced in support of it. To adopt such a measure from some vague sense of precaution, is as unphilosophic as it is likely to prove illusive.

If one half of the vaccinated are safe, as some suppose, what signs are there to indicate the particular kind of constitution comprehended within this fortunate moiety? It is evident they exhibit no premonitory signs by which we may recognize them. It is mere guess work. If, as it is generally admitted, a primary genuine vaccination do occasionally prove unprotective, what reason have we for concluding that a secondary genuine vaccination should prove more protective than the first? There is neither reason nor evidence to enable us to form any satisfactory judgment respecting it. And, even supposing the patient to be unprotected by the first, we have no test to assure us that he will not be liable to take the small-pox, in spite of his remaining insusceptible to the virus of a secondary vaccination. The value of a negative proof is very precarious.

The varieties and degrees of susceptibilities and insusceptibilities constitute a problem which no one has hitherto attempted to solve. Our information respecting vaccination in general is scanty enough, and practical writers have not thought it worth their while to bestow more than some passing thoughts upon it. The result has been, that theories have been broached, and allowed to pass current without challenge, inquiry, or remark; opinions have been mistaken for facts; and, excepting on a few rare points (such as the variolation of the cow), vaccination is now almost just where it was upon its first discovery.

A foreign writer, of the name of Wendt, recounts, that out of 275 revaccinated in the Danish army, more than half succeeded. But vaccination has succeeded, it is declared, in persons already deeply pitted with the small-pox, to the amount of one half, which is about the same proportion. Jenner himself at last perceived and owned, that the susceptibility to cow-pox is renewed in some constitutions—an admission which only shows that vaccination, like everything else on the earth, is neither universal nor infallible. Our just confidence in a remedy is weakened by overrating its value. Of the deaths from small-pox in some of the largest cities and towns of Great Britain, four-fifths occur in the first five years of life. If this account be authentic, then these children were either not vaccinated at all, or else, if vaccinated, they took the small-pox at the precise age when vaccination ought to be the most protective.

The question of revaccination is embarrassed on all sides. In times of danger from infection of the small-pox, it is unquestionably proper. For the most part, a genuine scar is the sign and seal of protection; and most vaccinators will feel confident that, in such a case, revaccination will in all probability produce nothing more than a spurious pock, running its course in five days; or that, if small-pox supervene, it will be only a mild form of it, terminating favourably in a week, and seldom proceeding so far as the fourteenth day. Should the attack, however, turn out a severe one, the medical man will be inclined to suspect the normal character of the primary vaccination; for he has a firm conviction,

or consciousness, derived from his own experience, that a genuine vaccination, carefully watched and approved of throughout all its stages, never deceives him. It is, in his estimation, proof impregnable against the small-pox infection, and of strength sufficient to resist the specific virus of revaccination. We may appeal to those who have been attentive observers of what has transpired within their own sphere of practice, and ask them whether this declaration does not express the unshaken conclusion of their minds? Testimony of this sort is of no trifling weight, and supercedes the nicest arguments which can be opposed to it. In a court of law, it would be decisive. Many a doubtful point, however, would be cleared up and settled by the returns of extensive statistical reports on vaccination, such as those of the Registrar-General's respecting births, deaths, etc.; and an arrangement of this kind might be provided for in a new Vaccination Act.

The proper age for vaccinating has been determined by necessity rather than by choice. The usual time is about the third month, nor does there seem to be any good reason against it. At this period, the pock usually succeeds very well, without interfering with dentition, weaning, or the change of dress, which is generally made lighter, towards the eighth or ninth month. Indeed, there is no time when the nursing and warmth are more carefully attended to than at this period, nor when the infant is more susceptible and less irritable than then. About this time, also, healthy children are plump, and they sleep a good deal, both of which are favourable conditions for vaccinating. The spring and autumn are the best seasons for obtaining fully developed vesicles. The winter checks the action of the skin, and the summer overheats and exhausts the surface. The one hurries on, while the other delays the progress of the pock. It is best to postpone the vaccination altogether in very cold weather, and to wait for a more congenial temperature.

Dentition by no means hinders the virus from taking effect; and every vaccinator is aware of vesicles being produced as perfect, and as much approved of, at this time as at any other; only the liability to secondary eruptions is greater, and the constitutional powers are engaged in the formation of the teeth, which is an important process, making a great call upon the strength, disturbing the regularity of the nervous centres, and occupying the chief activity of the system almost exclusively in its own operations. On this account, it has been recommended to postpone vaccinating until after the formation of the first teeth, or at least until after the expiration of the first twelve months. Except in some particular cases, there does not seem to be any good ground for giving way entirely to such a scruple.

No one would ever think of vaccinating during the existence of feverishness, sleeplessness, diarrhoea, catarrh, etc., in children; nor in adults during menstruation, an attack of indigestion, jaundice, excessive fatigue, care, grief, or any other accidental circumstance interfering with the general health.

The fourth month used to be the age at which the old inoculation was practised, and the child's health was prepared for its reception. Under the most favourable conditions, it was not free from risk; for sometimes the small-pox eruption came out over the whole body, and occasionally children died in consequence of it. During the incubation of the small-pox, that is to say, between the moment of infection and the appearance of the eruption, vaccination may be attempted. Its success will depend on its being performed nearer the moment of infection than that of the eruption. Some say that, if vaccination be effected within six days from that of the infection, the vesicle will arise, and anticipate or intercept the appearance of the small-pox. Others affirm that, even though vaccination should be attempted as early as the moment of infection itself, yet it will not do more than modify the character of the small-pox; while others, again, declare that, if vaccination take place consentaneously with the small-pox eruption, then the small-pox eruption will proceed *pari passu* with the vaccine vesicle. Nay, it is even asserted, that a confluent small-pox

will proceed along with a genuine vaccine vesicle. It is evident that these are abstruse points, almost beyond the reach of a private individual's experience. Nothing but extensive reports, spread over the space of several successive years, could furnish us with anything like positive data for working by. In the case of imminent exposure to infection, we are forced to vaccinate without delay, and trust to chance for its succeeding.

It is stated that, when a child has been vaccinated and inoculated at the same time, and almost on the same part, so as to allow of the vesicles uniting, the virus taken from this compound pock will produce either cow-pox or small-pox, no one can foretell which; and that inoculation with vaccine and variolous virus mixed will give rise either to the one or the other of the two diseases indiscriminately. These curiosities in pathology scarcely bear upon practice; perhaps they may be adduced in proof of the identity of the two affections; but their importance does not extend much beyond the limits of their own intrinsic value. Like many other phenomena, they begin and end in themselves, because we are ignorant of their exact relations.

As the greater number of children who die from small-pox, die between their birth and the second month of their existence, it is advisable to vaccinate the poor as early as possible. Their means do not enable them to isolate themselves, and live apart from the sources of contagion and infection, like the rich. Moreover, they are disposed to be negligent in this as in all other matters; and it is difficult to make them see the importance of being vaccinated at all, or, if vaccinated, of bringing their children to be inspected on the proper days throughout the progress of the pock. The consequence is, that, when seized with the small-pox in after life, they are said to have been vaccinated in their infancy; whereas the vaccinator had never been allowed to watch the vesicle, and therefore could never vouch for its protective quality. When I resided in London, I vaccinated many poor children; but, owing to the necessities or ignorance of this class of people, the vaccinations were desultory, and a great number departed or disappeared, without rendering any account of themselves. In instances like these, the appearance of small-pox after vaccination cannot be surprising. The fault does not rest with the medical practitioner, for he cannot control the caprices of the public. The wealthier classes contract small-pox through the indiscretion of their domestics, who visit infected places, and bring it back with them.

A child, on the eve of sickening for measles, etc., may happen to be vaccinated, and in this case the vaccination may not appear, but lie dormant until after the measles have passed away, and then come forth, and pass through its stages with apparent regularity. Every vaccinator is, I believe, aware of a genuine vaccination being delayed for two, more, or several days; and in some seasons the best virus fails in taking effect, no one knows why. The insusceptibility to vaccine is more frequently to be imputed to defective lymph, than to any constitutional peculiarity in the patient. Good lymph seldom fails in taking effect.

Hooping cough was at one time supposed to be cured by vaccination, but subsequent experience has not confirmed this theory. Some have considered that vaccination has cured eruptive diseases, while others affirm that it has produced or aggravated them. These notions most likely turn upon the old difficulty of distinguishing between the sequence and the consequence of events.

The secondary lichen after vaccination is urged as a strong reason against its practice. The virus is supposed to have conveyed something prejudicial into the blood, and thereby provoked scrofula, etc. But it is not easy to determine what is the immediate and exciting cause of scrofula, which may be attributed to many other causes besides vaccination. Anything may awaken it from its latent state, and render it active for a shorter or longer period, if not for the remainder of life. Be this as it may, the constitutional ailments which are said to follow upon vaccination, may be avoided by the use of purgatives (hydr. c. creta) proportioned to the patient's age and strength. All erup-

tive diseases require this treatment at their close, and the vaccine pock among the rest. In scarlet fever, the train of awkward symptoms which manifest themselves in the throat and kidneys may be removed by purgatives, exhibited for the space of three or four weeks during convalescence. It is the same with measles, in which the lippitudo and diarrhoea that threaten to supervene may be averted by the same means. It is especially the case with small-pox, which requires repeated laxatives on its cessation. Variolous inoculation, and its congener vaccination, call for the same treatment. The cachexy following eruptive diseases, fevers, inflammations, etc., may be traced up to the neglect of this wholesome practice; and the eruptions spoken of as occurring after vaccination may be ascribed to the same omission.

Lichen is apparently an inflammation of the nervous structure of the skin—a true hyperæsthesia, and the eruption is but an accident; for in many cases of prurigo there is no eruption at all. In plethoric subjects, salines, laxatives, and antimonials, together with the use of warm bathing, are the proper remedies; but in cold constitutions, and debilitated persons, the opposite treatment is called for, and stimulating the skin is the best practice. It is analogous to that asthenic conjunctivitis which is curable by stimulating lotions (argenti nitras), but which is aggravated by depletion. The prurigo senilis, so vexatious and obstinate in advanced life, yields to the popular remedy of beef-brine, with saltpetre dissolved in it. These few observations, respecting the nature and treatment of lichen, may not be out of place on the present occasion.

The foregoing account is not a very satisfactory one; and it is for this reason that I have reserved it to the last, and been at the pains of drawing it up thus succinctly. It is surprising how many loose opinions are afloat upon vaccination, and pass current for truth among the public. But if we deduct the few facts that are really known, we shall find the absolute data are only three: viz., 1, the source of genuine lymph, *i. e.*, the cow; 2, the natural history of the vesicle; and 3, its power of protection, when rightly performed. Other points, of not less vital importance, meet us at every step; but they are enveloped in doubt, elude our grasp, and escape from sight. They remain as subjects of investigation for the philosophic student; and it only requires a school, regularly organized, appointed, and authenticated, in order to bring them within the focus of enlightened research. The cow might be variolated from time to time, so as to procure a genuine supply of fresh lymph whenever it is called for; vaccine wards might be opened; vaccinators, as well as a lecturer on vaccine, might be officially installed; and pupils, accurately educated, might be sent forth, capable of discerning between a true or false pock, as well as skilful in the art of keeping up a constant succession of approved vesicles. At present we have nothing of the sort. The legislature may shift the scenery for us; but the chief and real actors in the drama must be those who preside over the destinies of the medical profession as its preceptors, guides, and friends.

Brighton, May 1853.

FREE WILL. "There is a certain difficulty in reconciling a free will with a superintending and guiding Providence. But take an analogous instance, where a man stands in the relation of a guiding providence to an animal. The horse has a will. Breaking in, the harness, the reins, the whip, the spur, all are proofs of the animal's will, and of the necessity of its training. The horse is harnessed to a vehicle, and guided by a man. So far as the animal's free will is exerted in the direction the driver chooses, the animal fulfils his purpose. Let him exert that will in opposition to his ruler, and he is driven by the lash to submission. So with man. He has a self-determining power, and as long as he submits that will to the obedience of his reason, enlightened by the Divine light, he is fulfilling his duty; he is working with and by his Maker; his will is in harmony with the Divine will. But deprive it of its freedom, and it becomes instinct; responsibility ceases, and the foundation of all freedom—law and self-culture—is destroyed."—*Evening Thoughts*. By a Physician. P. 29. Second edition. London: 1853.

BIBLIOGRAPHICAL NOTICES.

ON NEAR SIGHT, AGED SIGHT, IMPAIRED VISION, AND THE MEANS OF ASSISTING SIGHT. By WILLIAM WHITE COOPER, F.R.C.S., Ophthalmic Surgeon to St. Mary's Hospital. Second edition. Pp. 320. London: 1853.

WE are not surprised that this useful little work has reached a second edition. It has in many respects been thoroughly recast, and enlarged on the more practical topics; the chapters on Light and on the Physiology of the Eye having been judiciously omitted, to allow of that enlargement.

Many of our most esteemed works on ophthalmic medicine contain but an imperfect account of the changes in the optical powers of the eye, and of the effects of over use and misuse of the organ,—subjects which it is of at least as much importance thoroughly to understand, as to be acquainted with the varieties of ophthalmia, and the *minutiae* of the operations for cataract. Ophthalmia no doubt spoils most eyes among children; misuse, we fear, most among adults; and those whom cataract has deprived of sight are but as a drop in the bucket, compared to the multitude whose vision has been lost, or seriously impaired, by the diseases treated of in Mr. WHITE COOPER'S volume.

Chapter I treats of Myopia. Shortsightedness may in the first place depend upon original malformation of the refractive media of the eye; the image being formed in front of the retina, and the defect being, as every one knows, remedied by the use of a concave lens. Common, nay, even fashionable as this state is, it now and then happens that an eye has been considered by its owner as amaurotic, while it was only short of sight. Mr. Cooper gives a curious case, in which a very short-sighted person was enabled to read easily at twenty-five inches, by making gentle pressure with his finger and thumb on the upper and lower part of the eyeball, and so altering its figure.

It is of consequence, that when the aid of lenses is required, they should be worn in the shape of a pair of spectacles. It is a foolish custom to use a single eyeglass. Why throw one eye out of employment at the expense of overloading the other with double work? The glasses should also be of a power as low as will enable the wearer to see distant objects; and they should not be used in reading and similar occupations; but, on the contrary, every effort should be made to increase the distance at which near objects can be viewed, for "constant practice will lengthen the focus for near objects, and will enable the myope to read and write at an increased distance; but experience shows that, where the defect is congenital, little alteration takes place in respect to distant vision." (P. 40.)

Mr. Cooper describes the myopia which depends on chronic inflammation of the aqueous membranes, and consequent distension of the cornea; but he does not notice the temporary short-sightedness often occurring after iritis, apparently in connexion with some affection of the ciliary processes.

The second kind of myopia arises from a loss of the adjusting power of the eye. It occurs in those who have employed their eyes too much in study, or on minute objects, and is known by there being no change in the *reading distance*, while distant objects can be distinguished only by the aid of a concave lens. It is usually accompanied by more or less ocular congestion, and is to be treated by rest of the eye, improvement of the general health, and abstinence from the use of glasses. Mr. Cooper has, to a certain extent, mixed up together these two varieties of myopia.

The subject of Chapter II is Presbyopia; the long-sightedness, usually of age, remedied by the convex lens. There are some curious cases in which old persons, long accustomed to the use of powerful glasses of this kind, come to be able to see once more without spectacles as well as in their youth. One very remarkable instance of this kind

has fallen under our own observation; but we can, as little as Mr. Cooper, venture to adopt any of the explanatory theories which have been offered.

Long-sightedness may occur in early life, perhaps may be congenital; and it is often combined with, or even dependent upon, various congestive disorders of the eye. In such cases, the erring patient often resorts to glasses of increasing power, in the vain hope of curing by lenses a defect which can be removed only by a due attention to the vascular and nervous systems of the eye.

Chapter III is on Impaired Vision from overwork; a subject to a certain extent anticipated in the preceding pages, and under which general heading Mr. Cooper classes together a great variety of pathological conditions of the nervous, the vascular, the muscular, and the secreting tissues of the eye. Amblyopia, or irritability of the retina; amaurosis, or palsy of that membrane; asthenopia, or weakness of the adjustive power of the eye; choroidal congestion; nay, even external and internal ophthalmia of various kinds, are all alluded to, and the interesting cases given afford examples of most of these conditions. Each might have been separately considered; but we think Mr. Cooper has, on this occasion, judiciously abstained from such an analysis, which could be rightly given only in a work intended solely for the profession. This remark, however, bears not upon the execution, but upon the plan of the volume, which certainly exhibits traces of the inconsistency of purpose and want of harmony of parts inseparable from a treatise meant both for the profession and the public. We do not for a moment find fault with the latter aim; it is most praiseworthy, and none can write more usefully or more pleasantly than our author; but for our own part we must say, that we should choose to attain the objects in view by means of two separate treatises.

Achromatopsy, or the Inability to distinguish Colours, is the subject of chapter IV; and, like the essays on eye-protectors, and on snow-blindness, forms an interesting addition to the work in the present edition.

Males are most commonly the subjects of colour-blindness; but in an article on this subject which appeared lately in this Journal (April 15th, p. 334), the fact stated by Mr. Cooper was overlooked,—that M. Cunier had observed thirteen female cases of this defect in one family, and that four female cases occurred in the family of Dr. Pliny Earle.

We wish our limits would allow us to transfer to our pages Mr. Cooper's interesting analysis of the facts respecting colour-blindness, put on record by Wartmann and others. We are as little satisfied as he appears to be with the explanatory theories which have been proposed; and are inclined to the notion that the defect may turn out to be neither in the retina (of vision), nor in the brain (of perception), but in the optic ganglia (of sensation); and to be analogous neither to deafness nor to a want of taste for music, but to the deficiency in the power of discriminating between certain notes.

Chapter V treats of Glasses. After a demonstration of the optical power of simple lenses, and an interesting notice of the history of spectacles, which appear to have been earliest used by the Chinese in Asia, and by Roger Bacon in Europe, Mr. Cooper notices the mode of making lenses. He recommends that when irritability of the retina renders tinted glasses necessary, a *neutral* tint should be selected, and that the ordinary double convex lenses should be preferred to the periscopic. His rules for choosing spectacles are good. The eye should neither be strained by using too feeble lenses, nor have its focal power still further damaged by the employment of those which are too strong. When in the important matter of selecting spectacles, do people act so generally on their own opinion, while they consult professional advice necessary in matters of far less importance? Two points are often overlooked: each eye ought to be tried separately, lest they should differ in focal length, and the frame ought to be suited to the form of the individual face, so that the centre of each glass may be exactly opposite the pupil of the corresponding eye.

are next described; and those exceptional cases are noticed in which the eye preserves, after the operation, the power of forming a distinct image of moderately distant objects, without such assistance.

An experiment of M. Cunier's is recounted, in which he succeeded in restoring vision to an amaurotic (?) eye, by causing the patient to practise reading with magnifying glasses. This was in all probability merely a case in which the retina had become deficient in sensibility from disease of that eye.

Chapter vi contains an account of Eye-protectors. In an appendix to the work, an interesting description is given of the Snow-blindness, to prevent which in arctic regions, the eyes must be defended by an apparatus presenting only a small aperture or narrow slit for vision. Excessive intolerance of light, and intense pain, speedily followed by blindness, are the most prominent effects apt to be produced by the exposure of the eyes to the glare of light reflected from snow; but as complete recovery may take place in a very few days, without other treatment than rest of the organ, and the application of cold, it would appear that the disease is rather of the nature of determination of blood, with irritation of the retina, than inflammation.

Various useful forms of shades, goggles, and pierced diaphragms, with or without lenses, are described. The last-named apparatus is often of great service when the pupil is permanently enlarged, from disease or operation. Mr. Cooper appears, however, to place more confidence than we are inclined to do in the use of shades and other mechanical applications for the cure of strabismus. We venture to think that these will, in the great majority of cases, be found of no avail.

The last chapter contains a full discussion of the subject of Artificial Light; of the properties of the various lamps and candles, and of gas; and of the evil effects so often produced, not only by the overuse or the misuse of artificial light, but also by the want of ventilation of the rooms in which our artisans in many cases work. We have not space to follow Mr. Cooper throughout this discussion; but we would simply state that, the desideratum being a steady white light, of moderate intensity, and which can be easily managed, we are of opinion that the best form of artificial light is *gas*, burned in a swallow-tailed jet, the flame being surrounded by a globe of ground glass tinted of a pretty deep purplish-blue colour, deep enough, we mean, thoroughly to neutralise the excess of yellow rays in gas-light; the effect, of course, to be judged of during the day. The whole apparatus ought to be suspended at least three feet above the table, so that the luminous globe may be quite out of the field of view of the reader's or worker's eye; the room being, we need hardly add, well ventilated.

Such is a brief epitome of Mr. Cooper's work. It is throughout well and elegantly written, and remarkably free from accidental errors; the only one of any consequence which we have noticed is in p. 71. No one knows better than our author that the *index* of refraction is quite independent of the *form* of the refracting body.

ATLAS OF PATHOLOGICAL HISTOLOGY. By Dr. GOTTLIEB GLUGE. Translated from the German by JOSEPH LEIDY, M.D. Twelve Copper-plate Engravings. 4to, pp. 100. Philadelphia: 1853.

THE beautifully executed *Atlas* of Dr. GLUGE goes far to fill a desideratum in pathological science; for, while we can readily refresh our knowledge of the characteristics of healthy tissues by frequently examining them with the microscope, it is not so easy to pursue a similar course with regard to pathological formations, many of which come but rarely under notice—especially of those who do not enjoy the opportunities afforded by the operating theatre and dead-house of an hospital. Some of our fellow-associates have doubtless experienced this difficulty. Desirous of keeping pace with the advance of knowledge, they have, in their rural retirement, endeavoured to make out by the

microscope what was the nature of this tumour which they had removed, or of that structural change which some tissue seemed to have undergone; but, either from not having seen the appearance before, or from having forgotten it, they have relinquished in despair the pursuit of their investigation. Representations of pathological formations indeed exist; but they are too widely scattered in different books to be accessible to the isolated practitioner.

Dr. Gluge commences his work by an introduction on the magnitude and weight of the organs of man in the normal and abnormal conditions. In this we find the following important suggestion:—"I deem it essential" (in determining the size and weight of organs in health) "that all the important organs of an individual should be healthy, and not merely the one examined; for the reciprocal influence of organs during life is too great to lead to correct results, without their general condition being taken into consideration." The same introductory chapter contains a summary of the "pathological phenomena and truly characteristic anatomical alterations" in cholera.

Section I treats of the Development of the Elements of Tissues. Dr. Gluge is thoroughly impressed with the idea of analogy between physiological and pathological cell-development; and, in a subsection on the parallelism of these processes, he demonstrates this analogy by examples. In speaking of inflammation-corpuscles (exudation-corpuscles), he says:—

"It has been very learnedly shown that similar bodies appear in the colostrum and in the egg; but I have in no case asserted that they are found only in inflammation; and, on the contrary, I have ever tried to harmonize the pathological alteration of organs as much as possible with physiological development; for I have always viewed disease as nothing more than a physiological process modified by accidental causes." (p. 33.)

There is a deal of truth in this observation.

Section II is devoted to an examination of the Elements of the Tissues combined in Perfect or Imperfect Tissues, and arranged according to the Processes of Disease.

Section III contains an examination of the Formation of the Blastema. In this section, the phenomena of inflammation—congestion, hyperæmia, stasis, exudation, and gangrene—are reviewed.

Section IV treats of the Histological Metamorphosis of the Blood, within and without the Blood-vessels.

Section V is devoted to Pyæmia. Opinions, as is well known, are divided as to the nature and cause of this condition. Dr. Gluge says:—

"Pyæmia consists in a commingling of pus with the blood. The pus is either the result of the transformation of a portion of the latter, or it obtains entrance into the circulation through veins accidentally opened. The consequence of the admixture almost always, though not necessarily, is stasis in the capillaries, and the conversion of the blood of these into pus, with the formation of abscesses; and in this manner the latter may originate in greater or lesser number in the liver, spleen, kidneys, lungs, brain, and more rarely in other organs, as beneath the skin, in the muscles, and in the joints. This transformation of blood into pus is most frequently induced by the spontaneous conversion of coagulated blood into that material." (p. 51.)

"The irritation of the lining membrane of veins by means of foreign bodies, according to my experiments, neither induces redness in nor deposit upon it; and the same is the case with the lining membrane of the arteries." (p. 52.)

"The principal cause of pyæmia is coagulation of blood in the veins, which then undergoes conversion into pus, and is thus conveyed into the capillaries." (p. 53.)

"It is not pus-corpuscles which form metastatic abscesses; but, with fibrinous flocculi, they give rise to stasis and transformation of the blood in the capillaries, and exudation from these, which result in the abscesses." (p. 55.)

If space allowed, we should like to examine Dr. Gluge's views of pyæmia, comparing them with those of other observers; but we must, having made the above brief extracts, merely recommend his statements to the careful consideration of our readers.

Section VI treats of Gangrene.

Section VII consists of a collection of Observations in Histology.

The twelve plates contain three hundred and twenty figures.

Plate I represents Transformation of the Blood: Inflammation-Corpuscles: Pus. (When not otherwise specified, the figures are magnified 255 diameters.)

Plate II represents Granulation: Hyperæmia: Exudation.

Plate III contains representations of Stearosis, or fatty degeneration.

Plate IV represents Cartilaginous and Osseous Growths and Transformations.

Plate V contains delineations of Cells, Fibres, and Cell-fibres, in Tumours.

Plates VI and VII represent the Formation of Fibres and Cells in Cancer.

Plate VIII represents the Glands and Epithelia in Typhoid and Scarletina: Tubercle: Glanders: and Gangrene.

Plate IX contains representations of the Glands and Epithelia in Cholera.

Plates X, XI, and XII represent Entozoa, Epizoa, and Epiphyta.

Great credit is due to Dr. LEIDY for the manner in which he has performed his task, and for having rendered accessible to the Anglo-American practitioner and student the valuable *Atlas* of Dr. Gluge.

WHITE, RED, AND BLACK; or Sketches of Society in the United States during the Visit of their Guest. By FRANCIS AND THERESA PULSZKY. In three volumes. London: 1853.

THIS is a most instructive and entertaining work; but it scarcely comes within the sphere of the medical reviewer. There is one passage, however, which we have marked for quotation, as it gives one of the most graphic sketches which we have met with of a peculiar form of epidemic insanity, which has lately reached Europe from America. It has broken out with considerable violence in London, where those afflicted with it are furnishing an abundant harvest for professional swindlers.

As both in America and Europe young ladies form the vast majority of those who have to do with spiritual rappings, we quote, along with the sketch to which we have referred, a portion of the context, which gives us a little insight into the routine of female education in the United States. The writer dates the following from Cincinnati.

"SPIRITUAL RAPPINGS, MESMERISM, AND PSYCHOMETRY.

"On the 23rd, we visited Farmer's College. We could not insist in detail, for we had to hear a speech of one of the teachers, to which Kossuth was expected to answer. The students and the pupils from the Ladies' College in the neighbourhood, formed a very numerous audience. One of the trustees of the establishment introduced the girls to us, saying, 'These are the sweethearts and the future wives of the students'. The indelicacy of this remark appeared to me very inappropriate, both for the students and for the young ladies; yet, except our party, no one else seemed to observe it. Here in the West, I noticed a style of conversation, very different from what we are accustomed to in the society of Europe, and of the Atlantic cities of America.

"Large schools for young ladies, where they board, are to be found all over the United States, but home education is still rarer in the West than in the East. The wealthy merchant or lawyer sends his daughter to the fashionable schools of New York and Boston; but the shopkeeper, mechanic, or farmer, wishes likewise to have his daughter instructed in sciences and arts, and therefore we see often here such monster establishments, where two and three hundred girls live under the same roof, and learn something of every science and art—classics and mathematics, mental philosophy and astronomy, drawing and music, dancing and languages; then they marry a Western man, and must cook and sew, and often wash and iron, when they cannot get a servant; in short, they must set about just the very things which they have never been taught in the college.

"Another phase of female life in the Western cities struck

me very much. When in Columbus, a very sensible gentleman mentioned to me, that there are persons in the United States, and especially in the West, who have communications with the spirit of deceased persons. I was much amused by hearing this, and began to speak jestingly about the matter. To my great astonishment, however, I found that the gentleman was in good earnest. He told me, that some years back, in a certain house in Rochester, Western New York, rappings were heard, which could not be accounted for in any natural way, and tables and chairs were moved without any visible agency.

"This is the German goblin, the *Poltergeist* of the nursery tales,' exclaimed I; 'you can trace him to the Arabian Nights. Is it not quite curious to find him here, residing in the far West?'

"No, no,' said the gentleman, 'these are spirits of deceased persons.'

"How can you prove it?'

"Well,' answered he, 'we Americans investigate everything, and it was soon found out that three rappings mean *yes*, and two *no*. Questions were put, and the replies proved almost always correct; they often were quite astonishing. The communications became more frequent, and several ingenious inventions were made to get longer answers from the spirits. For instance, an alphabet was taken; the letters were numbered, and the spirits marked by rapping the number of the letter which they wished to be reported. For *a* they rap once, for *b* four times, and so on. But later, the spirits prepared for themselves *writing* and *speaking mediums*, who write and speak without any volition. They don't know what they are writing; their hand is moved by the spirits. Most of them do it with closed eyes, and often about matters and in languages they do not understand. Several books have been written in this way.'

"And what are the subjects of these revelations?'

"They treat on the condition of the spirits in the other world. How they are taught there by more perfect spirits, and how they migrate to higher spheres, until they reach the seventh. But we have as yet no description of the highest spheres.'

"Justinus Kerner, the German poet,' said I, 'would here have his delight. What you tell me is the continuation of his *She-Seer of Prevozt*. Do spirits here too drink beer, as the German spirits of Justinus Kerner did? And is the American free-school system also possibly introduced in heaven? At least, one of Kerner's *Seers* (as the Germans call your mediums) found the Würtemberg school-system introduced there.'

"You jest,' said the gentleman; 'but I can assure you, that sincere men of sound judgment and of good education have had visions. Judge Edmonds, for example, of the New York Supreme Court. And is not the last communication from Benjamin Franklin, by rappings through a young girl of twelve years, entirely in his style and his turn of mind? To use time well, does not mean to do the most in an hour, but in a lifetime.'

"Then you believe in all these manifestations, sir?' asked I, astonished.

"There are,' said he, 'I must confess, statements which are not to be relied upon. In one of those chronicles of spiritual manifestations which abounds in poetical beauties, we find that the spirits are taught French and Italian in the other world, that they may understand Racine and Dante, which is rather strange, so much the more as the German language is not mentioned. Besides, the spelling of the spirits is sometimes wrong. Nevertheless, the rappings I myself have heard repeatedly, and I cannot find any physical explanation for them. Like many other people in the United States, I do not believe; but I do not disbelieve. I register the facts, and wait either for a natural explanation, or for an evident proof of supernatural communications. Horace Greeley has, as I hear, offered to a medium a hundred dollars for every leading article of the *London Times*, communicated to him in advance of the steamer.'

"And has this test been successful?'

"No,' answered the gentleman; 'the medium declined the proposal, but positively stated that Sir John Franklin is yet alive, and will be discovered in September.'

"I dropped the conversation. I remembered that in Germany, such alleged manifestations had been fashionable for some time, but they soon disappeared in this *arctic* ~~land~~ and merged into the phenomena of Mesmerism. Some others, in the midst of rappers, and mediums, and ~~table-turners~~ ~~and~~ the first week of our stay in Cincinnati, Captain ~~Edmonds~~ ~~and~~ that the Misses Fox, with whom the rappings were first heard in Rochester, were staying at the ~~Bureau~~ ~~of~~

rooms. He had already paid them a visit, and was astounded by the rappings themselves, and by the answers conveyed in this manner. Yielding to his entreaties, I went with Mr. Pulszky into the room, where we found the two very handsome Misses Fox, their mother, several of the Hungarian gentlemen, and two reporters.

"The manifestations immediately began. The young ladies requested us to put questions. I naturally asked: 'Shall we return to Hungary?' Three distinct raps were heard on the table from below; the table was uncovered, Miss Fox stood near it, keeping her hand on the edge of the table. I closely watched her movements; the rap did not proceed from her. I asked several other questions of a similar kind, and got just as favourable replies as I could wish. Of course, I did not care for them, though one was remarkable. Asking the age of my eldest boy, I was bid to write down a series of different numbers; at the right one, the spirit would rap—and this was the case. But such things have been exhibited often, by Bosco and similar magicians. It interested me more to investigate how the raps were produced. At my request, raps were heard on the window-pane, on the door from without, and under the floor. Miss Fox even put four tumblers on the table, and stood upon them, to convince us that it was not she who rapped, and yet the rappings were heard on the table. Doctor Spaczek, our clever physician, was likewise present. He too could not tell in what way the rappings were produced, but he rejoiced at least to get an evident proof that they came not from the spirits of deceased persons. He asked whether his father was in heaven? Three raps answered 'yes,' whilst the father of our friend lives in good health in Poland. The spirits likewise were at a loss to guess how old Mrs. Spaczek was; they added ten years to her actual age. When the doctor began to protest against these manifest falsehoods, Miss Fox coolly replied, that she and her sister were not responsible for anything the spirits said, as they, in fact, could not tell whether the spirits who manifested themselves were veracious or lying spirits. That there were lying ones amongst them, they had found out by experience.

"On the next day, our visit to the rapping spirits was duly trumpeted and commented upon in the papers. As the exhibitions of Misses Fox are for an entrance fee, I was not surprised at this progress of 'the philosophy of advertising'. But the newspaper report became an introduction to us for the spiritual circles of the city. We were mistaken for believers, and got invitations to several of them.

"I understood that a spiritual circle is formed in the following way:—a number of persons who are not sceptic, and amongst whom one at least must be a spiritual medium, sit silently around the table, holding one another's hand, and concentrate their minds. If they meet in such manner at least once a week, the spirit manifestations begin. Rappings are heard, writing mediums are formed, others become clairvoyants. There are several such circles in Cincinnati, and the spirits who manifest themselves through the mediums, are generally George Washington, Andrew Jackson, Benjamin Franklin, Zachary Taylor, and Emanuel Swedenborg. There are besides two spirit messengers amongst them, and the spirits of the nearest relatives of those who form the circle. Even Sir Robert Peel has made his appearance, and, strange to say, he has become a thorough republican in the other world, predicting the approach of republican governments all over Europe, and even in England.

"When I saw how far this singular belief had spread here, my curiosity was roused, and my husband began likewise to interest himself in the psychological problem, how it comes that such a practical people as the Americans can entertain such fantastic and extravagant ideas. One of our American friends, in whose family several female mediums were found, professed to have examined the matter earnestly, and to have come to the conclusion, that the manifestations really proceeded from spirits; that there was no cheat, no imposture, though some of the spirits were evidently lying spirits. He had cross-examined one who had pretended to be Emanuel Swedenborg, and had found that he did not understand Latin, and did not know the titles of his own works. But the belief of this gentleman was yet unshaken; it was a lying spirit, but a spirit it was! He assured us, that all the spirits took great interest in Kossuth and his cause, and prophesied the speedy liberation of Hungary.

"In the evening, we visited one of the spiritual parties to which we had been invited. We found there about twelve persons: gentlemen, ladies, children. One of the ladies shook her right hand violently and nervously. 'She will become a

writing medium,' whispered our host to me; and pointing to another lady, who seemed to be asleep, 'we do not know yet,' he said, 'what medium she will become.' Among the others, there was a good deal of laughing and chatting, certainly no solemn mood prevailed. At last they grew silent, the circle was formed by the connexion of the hands. We listened, eyes were closed, breaths audible. But the spirits did not seem to like us; for no manifestation ensued. One of the gentlemen present laid his ear on the table, and said: 'he knocks, but very slightly.' I remarked, that I had not heard anything. 'Amos!' exclaimed one of the ladies, 'are you present?' The gentleman again listened to the table, and said: 'he knocks.' 'Amos!' continued the lady, 'will you bring us any manifestations to-night?' The gentleman assured us, that he had heard but two knocks, a negative reply. 'But who is Amos?' inquired I. 'It is the spiritual messenger,' was the answer.

"In the meantime, a very handsome lady, with a sweet expression, had fallen asleep, and began to be clairvoyant; but she saw only her father, and did not reveal to us any transcendental thoughts or facts. The bell of the street-door was now rung, a letter was brought in, and our host read aloud:—

"'Can you spare Amos to-night? We have formed a circle, and have summoned him, but he does not appear; we presume he is detained with you.'

"'We cannot spare him,' was the general answer, and Amos was not dismissed. He must have been annoyed, for he remained obstinately silent. We got no manifestations, no rappings, no letters, no speeches; we went away, and were invited for another day.

"We called again on the 23rd of February, the anniversary of the birthday of Washington, at Mr. —'s, and were told that the spirits had promised a series of manifestations. We entered the room, followed by a young lady and her husband; she was introduced to us as a medium. In the second room, an elderly lady, clad in sprightly green, with a smile on her radiant face, sat on a chair, and shook both her hands violently. As she beheld Mr. Pulszky, she stretched her arms out over his head, and advanced towards him. He retreated to the wall. 'What is she doing?' inquired I. 'She is blessing him, in Washington's name,' replied our host. 'We do not know her; she was sent to us by the spirits, who told her that you would visit us to-day. She came at their bidding. There is also an old gentleman whom we do not know, and who likewise was sent by the spirits.'

"We sat down to the table, and scarcely was the circle formed, when the elderly green lady began to shake her grizzly curls, whilst an old periwigged gentleman, on the opposite side of the table, uplifted his tearful eyes. The green lady stretched out her hands, and spoke with a solemn tone, word after word, as if it were dictated to her:—

"'Let the Lord have all the praise! To me this is the happiest anniversary, and there will be lasting good come of it, to all who will receive me and all I may say. I am rejoiced to meet all who are here. And the Lord will be with His viceroy, who has been kept away by physical infirmation. I bless you all in the name of the Lord, who rules over heaven and earth.'

"GEORGE WASHINGTON."

"I thought the communication was not less strange than the style of George Washington, and glanced at our host. He seemed to understand me, and asked the green lady whether they had ever before had communications of George Washington in this circle.

"'You shall have them in future,' said she.

"'But who was then the spirit who wrote through our medium, signing George Washington?'

"The green lady did not answer, but closed her eyes, and began to bless Mr. Pulszky and me, and kissed Madame Kossuth, and gave her a blessing in her mother's name.

"'What is the name of Madame Kossuth's mother?' asked our host.

"'So many names are fluttering before me,' said the green lady; 'I see them, but I can't read them. Names, names, names, hosts of names. Mary, Sarah, Margaret, is it not one of them?'

"Madame Kossuth shook her head, the company seemed disappointed.

"A young lady had fallen asleep, and wrote a couple of verses. But the poetry of the spirits was as poor as their prose; yet her brother exclaimed, surprised, 'She never in her life has made verses before!' Another very pretty young lady leant backward on her chair, as if exhausted, in a very becoming statuesque position. In the streets drums were heard, the

militia passed the house, and one of the ladies exclaimed, 'An army, an army all around me!'

"Can you tell me which army?" inquired our host. 'I dare not ask, I promised to obey,' was the answer. 'All curiosity must be laid aside, all will be cleared in the right time.'

"But meanwhile, our guests should be convinced by a test," remarked our host. 'Will you answer some questions in respect to their relatives?'

"The lady nodded.

"Where is my uncle?" asked I, in Hungarian.

"All shall be done in the right time," was the answer.

"This was conclusive enough; yet the gentlemen in the circle seemed not to feel how ludicrous they appeared. One of the ladies wept, another laughed; a medium handed a line to Mr. Pulszky, containing the words, 'You had better go!' and so we did. I was no longer astonished at the great number of insane persons in this country, above 15,000 in twenty-three millions; '150 per cent. more, in proportion, than in Hungary.'

"The Americans, especially here in the West, have little leisure to enjoy nature, no art to refine their feelings; their manners proscribe the amusements of Europe. The soul must grow weary of the tinkling of dollars, of the purely material aim of their life. They long for excitement; the ladies grow nervous, and work themselves into trances and visions, and cheat themselves and others. Spiritual circles are formed in lieu of balls, and concerts, and theatres. The gentlemen attend these representations, and are too much worn out by business to look deep into the matter. Besides, such fancies become epidemical. I remembered that it is here in the West, where, in the camp-meetings and the forest-gatherings of the Methodists, people get spasmodic contortions, and begin to roll, to jerk, to dance, and to bark. They have visions and trances, and are thrown into a state of ecstasy similar to a protracted catalepsy. One of the gentlemen who had come from Turkey with Kossuth, said, that when he saw at Broussa, for the first time, the *howling Dervishes*, when they began slowly to move their head forward and backwards, repeating incessantly, 'God is great', and went on accelerating their movements and raising their voice until they got fits, and foamed and fainted, as if possessed, he himself was nearly tempted to join their chorus, and to exclaim with them, 'God is great'. It was in the same country that the orgiastic dances of the followers of Cybele astonished the world, edified the illiterate, and disgusted the learned. And similar psychological phenomena returned again, after centuries, here in the West! I fear that the great progress of which our age boasts is only a progress in the instruction of the understanding, not in the education of feelings. The believers of spiritual manifestations are on a level with the early believers in witchcraft in New England.

"Far more interesting, though not more convincing, than the 'spiritual manifestation', for me, was the *Psychometry* of Doctor Buchanan. He is a clever phrenologist, an able author, an adept of Mesmer and Spurzheim. He told us that he had often found persons of such delicate perception, that when a letter is put on their forehead, they can describe the moral character of the writer, and he calls this phenomena 'Psychometry'."

SIGHTS AND SOUNDS: the Mystery of the Day, comprising an entire History of the American "Spirit" Manifestations. By HENRY SPICER, Esq. 8vo. pp. 480. London: 1853.

THE monstrous improbabilities and transparent fooleries recorded in this volume, find crowds of readers and believers in this metropolis. The librarian, from whom we borrowed it, informed us that no novel of this or any season had been more eagerly or more extensively in demand among his clients. In connexion with this fact, its perusal cannot fail to suggest to the student of psychology themes for meditation. We have our own notions on spirit rappings and turning tables, which we propose some day to lay before our readers.

"TO DAIMONION", OR THE SPIRITUAL MEDIUM: in Twelve Letters to an Inquiring Friend. By TRAVERSE OLD-FIELD. 12mo. pp. 167. Boston: 1852.

WE cannot concur in all the views of the writer of this little volume; but his remarks upon *re daimonion* are, upon

the whole, so ingenuous and so imbued with religious feeling, as to command respect, and convey instruction. The work is not yet much known in London. It may be had from Trübner and Co., 12, Paternoster Row, to whom we are indebted for the copy now before us, as well as for other recent transatlantic publications.

PERISCOPIC REVIEW.

PRACTICE OF MEDICINE AND PATHOLOGY.

SPASMODIC ASTHMA.

IN No. 1 of the *Glasgow Medical Journal*, Dr. EBEN WATSON has commenced a series of contributions on the pathology and treatment of Diseases of the Chest. In the paper before us, he treats of spasmodic asthma. The following is an abstract.

We find from Dr. Strang's statistics (Report on the Glasgow mortality bill for 1851, p. 46), that in the year 1851, 213 persons died of asthma in Glasgow; and in 1852 (Report on the Glasgow mortality bill for 1852, p. 28), rather fewer, viz., 202. Now, by the same tables, we also find that the total deaths from all causes, among persons above fifteen years of age, amounted in 1851, to 4543, and in 1852 to 4853; and seeing that asthma very rarely attacks persons below fifteen years of age, it follows that these two numbers afford the means of ascertaining the ratio between the general amount of mortality, and that accruing from asthma. Regarding, therefore, the adult population alone, viz., persons above fifteen years of age, one death was caused by asthma, in 1851, for not more than 20.4 by all other diseases put together; and in 1852, one death was caused by asthma for 23 by all other diseases. Or, to take another view of it, of all deaths happening to persons above fifteen years of age, 4.6 per cent. in 1851, and 4.1 per cent. in 1852, arose from asthma.

The name of spasmodic asthma was originally founded on the mere supposition of a spasm in the air passages, occurring so as to cause the sudden paroxysms of dyspnoea, to which the patient is liable: and now that the structure and functions of the bronchial tubes have been thoroughly investigated and made familiar to every one, we do not suppose, but we know, that such a spasm really occurs; so that in this instance modern science has confirmed ancient hypothesis. There are only two portions of the air tubes where spasm can at all take place, so as to cause dyspnoea. These two portions are at the rima glottidis, and at the extremities of the bronchial tubes, where, instead of cartilaginous rings, there exist muscular fibres. In all other parts of the bronchi, the rings of cartilage in their outer walls prevent anything like complete closure.

Laennec observed that during the asthmatic paroxysm there was great diminution, or even complete absence, of the respiratory murmur; a fact which is explained by the small tubes being obliterated by the spasm, so that the air cannot pass into and distend the air-vesicles. When the spasm begins to relax, the patient inspires slowly and with difficulty; a vibratory sound, accompanying the inspiration, is heard by the bystanders, and much more loudly through a stethoscope placed over the thyroid cartilage. It is caused by the vibration of the glottis, still partially stretched over the entrance to the windpipe. Sufficient importance has not been attached to the spasm of the glottis in asthmatic cases; it is the glottidean contraction which chiefly hinders the patient from overcoming that of the much weaker fibres of Reisseissen in the smaller bronchial tubes. As soon as the muscles of the glottis relax, and not till then, does the respiratory murmur become re-established.

Observation thus teaches us that the *superior constriction* is the last to give way; and Dr. Watson believes that, in early cases of asthma, it is the first to occur. There are two circumstances which prove this satisfactorily to his mind: first, the fact that many cases of purely laryngeal disease end in spasmodic asthma; and, second, that there are cases, though perhaps not very common, in which the affection is confined to the glottis.

In a paper on Chronic Laryngitis, published in the *Dublin Quarterly Journal of Medical Science*, in November 1850, Dr. Watson stated it as his opinion, that inflammation of the larynx, especially if ulcers have formed, constitutes a not infrequent cause of bronchial asthma, and supported this opinion by the relation of a case, occurring in a lady, who had acute laryngitis producing ulceration, and passing into the chronic state. Afterwards, not only the usual symptoms of the laryngeal disease remained, which were persistent, but she was excited, viz. spasmodic asthma, in a most violent manner.

The bronchial tubes ultimately became altered by the violence of the morbid agency that had attacked them. It was not to be expected that at this late stage of the disease any treatment could produce a perfect recovery; but it is satisfactory to be able to state, that after the cure of the laryngeal ulcers by the topical application of solution of caustic, the lady had no such severe asthmatic paroxysms as those from which she formerly suffered.

The occurrence of a kind of asthma confined to the glottis will be sufficiently illustrated by the following case.

CASE. A young lady consulted Dr. Watson about two years ago, for sudden attacks of breathlessness. She had no cough of any consequence, and in the intervals of the attacks she breathed freely enough; but as she seldom enjoyed a night's rest, her general health was somewhat disordered. Her pulse was quiet and natural, and there was no evidence of heart-disease; but her complexion was slightly florid, and her lips were of rather a bluish tinge. When he saw her, there was none of the bronchitis which generally attends asthma, and her age forbade the supposition of its being the ordinary kind of that disease. The respiratory sounds in the larynx were loud and harsh, and the exaggerated length of the inspiratory sound was exaggerated.

The fits of dyspnoea were worst at night and in the morning. When the disease was mild she could, by keeping very quiet and still during the evening, avoid the breathlessness for the early part of the night, and thus she got sleep for a time; but soon after midnight she was sure to awake with frightful dyspnoea, and was obliged either to rise from bed, or, at all events, to spend in a sitting posture the rest of the time usually allotted to sleep. Before she came to Dr. Watson, however, she was always attacked in a similar violent manner in the evening, so that it was only after being completely worn out that she obtained a short repose, from which she was again roused by extreme breathlessness. There was no approach to hysteria.

No other treatment was used but the regular application of a solution of caustic (3i to 3i) to the affected part, at first every day, and afterwards every second day. About six weeks of this treatment sufficed to remove the symptoms, and the lady remained quite well until the following winter, when she caught a slight cold and became affected in a similar way, but she applied to Dr. Watson sooner than on the former occasion, and half the time of the same treatment again produced a cure. During the autumn she again had another attack of her disease; but this time it was so slight, and treated so early, that it did not resist the topical application above a week. Since then she has been entirely free of the spasms, notwithstanding the very changeable and trying weather of the past winter.

Dr. Watson then concludes, 1st, that local causes of irritation in the larynx may produce spasmodic contractions, not only of the glottis, but also of the lesser bronchial tubes; and 2nd, that spasmodic affections of the glottis may occur periodically for a length of time, without involving the small bronchial tubes in any great or important contraction. These conclusions, if correct, prove that asthma commences in the upper and not in the lower parts of the air tubes; and that, in the rational treatment of that disease, the remedies most likely to benefit the patient are such as may be applied to the laryngeal lining and to the glottis itself. But it must be remembered that in many of these cases, universal bronchitis exists along with the spasmodic affection of the upper and lower tubes: this may arise either from causes capable of exciting both diseases, or the bronchitis may have existed previously to the occurrence of an asthmatic paroxysm. The former is then probably the exciting cause of the latter; and he admits that it is difficult, nay, perhaps impossible, to ascertain with accuracy, in this class of cases, whether the spasmodic affection was first excited in the small tubes, or at the top of the larynx. It is enough for practical purposes, however, to know that the latter region is always affected in such cases at the same time as the inferior bronchi, and with even greater intensity; and, moreover, that it is the spasm of the glottis which chiefly maintains that of the bronchi, by preventing their expansion during the forcible inspirations of the patient.

The ordinary treatment by bleeding, general or local, by emetics, antispasmodics, opiates, and mercurials internally, with blisters and various other counterirritants externally, has seldom been followed by even a partial success in these cases. It is established both by clinical observation and by Dr. Williams' experiments,* that bleeding carried to any length can never diminish the tendency to spasmodic contraction in the air-tubes;

but during a bad fit of asthma, such a measure may be absolutely necessary to relieve congestions, arising secondarily, either in the brain, or in the lungs themselves. Again, though emetics cannot save the patient from a renewal of the spasm, they may assist in overcoming that which exists, as well as in clearing away the mucus which clogs up the smaller tubes; and antispasmodics may assist in prolonging their good effects for a short time. In some cases where there is much bronchitis, blisters have a good and more lasting effect, but they do not exercise much influence over the spasmodic asthma. In like manner, a slight mercurialization often benefits the bronchitis of the more sthenic variety, as indicated by the expectoration containing plastic matter, mixed with mucous globules, but it can have no effect on the paroxysmal disease. Opium only lulls for a time—an effect by no means to be lightly esteemed—but when the paroxysm becomes severe it utterly fails.

There is here, therefore, an evident blank in therapeutics. There is no agent hitherto proposed which is capable of removing or greatly diminishing the morbid contractility of the air-tubes. And Dr. Watson thinks that a solution of caustic applied to the interior of the larynx supplies this defect. In proof of its having this exhausting effect on the irritability of the glottis, and ultimately on that of the air-tubes, he refers to the results of its use in whooping-cough, a disease which is so analogous to spasmodic asthma in its pathology, that it is almost enough to show the efficacy of a remedy in the treatment of one of these diseases, to prove its suitability for the other. Now, in proof that the topical treatment of whooping-cough is most efficacious and successful, it is enough to state, that, combining the cases treated by him since he first proposed the plan in 1849, with those treated by M. Joubert, of Cherion, and published in the *Bulletin de Therapeutique*, for January 1852, we have as follows:

	Cases.
A speedy cure (in ten to fourteen days) resulted in .	78
Shortening of disease (three or four weeks' duration) .	39
No change was effected in .	8
Total number treated .	125

There was not one death among all the cases treated, and taking their per centage, we have

62.4 . . .	were cured within a fortnight.
31.2 . . .	were cured in three or four weeks.
6.4 . . .	resisted the treatment.

100.0

He feels assured that no similar statement could be made regarding the results of any other method of treating whooping-cough.

He cannot, as yet, speak of great numbers of cases of spasmodic asthma treated in this way; but he has been very successful with the topical method in some cases that had previously been treated without much benefit in the ordinary manner. Of this he gives two instances.

Heart-disease is a frequent concomitant of asthma, and in such cases it is often supposed that the former is the cause of the latter disease; but this is by no means the constant relation of the two morbid states, for the disturbance to the pulmonary circulation, occasioned by frequent asthmatic paroxysms, is quite as likely to produce the heart-disease as the reverse. It is, however, more important to call attention to the fact of the great difference between simple spasmodic asthma, and that which coexists with heart-disease. The pathology of the former has already been explained as an affection wholly confined to the bronchial tubes. But in cardiac asthma, this is, Dr. Watson ventures to say, never the case. In that disease, the substance of the lung is always more or less altered; generally the air cells have become much distended, their walls atrophied, and even in some places ruptured; and it is this vesicular emphysema, not spasmodic contraction of any part of the bronchi, which produces the urgent thirst for air so distressingly experienced by these patients. There could be no good object served by introducing solution of caustic into the larynx in such cases.

There are, besides the topical application to the larynx, two other remedial measures which Dr. Watson has for some time employed in cases of spasmodic asthma, but regarding which he is not able to speak with precision. The one is electricity, applied, in a gentle current, as much as possible along the course of the larynx and bronchi. In his experiments on the lower animals, Dr. C. J. B. Williams found that such a current destroyed the contractility of the tubes,* and in several instances

* Report read by Dr. C. J. B. Williams, at the meeting of the British Association in Glasgow. See his work on *Diseases of the Chest*, p. 320.

* See Report formerly referred to.

Dr. Watson has thought that it co-operated with other means, in diminishing the frequency and severity of the asthmatic paroxysms. This, however, might be the effect, not only of its local, but of its general action as a tonic on the nervous system. The other agent referred to is strychnia, which he has used in repeated small doses of one-twentieth, or one-sixteenth part of a grain, and he believes with good effect in some cases. Dr. Williams found that when animals had been poisoned by this substance, the air-tubes did not exhibit contractility, and he thought that they were retained in a tonic spasm by the operation of the poison. This very probably was the case, but of course the use of strychnia in medicinal doses produces totally different effects on the human system, and the benefit accruing therefrom must have another explanation. Dr. Watson believes that this medicine, in the doses mentioned above, is a powerful equalizer of nervous action, and therefore a good means of diverting that action from concentrating in any particular organ, such as the bronchi in spasmodic asthma.

In conclusion, Dr. Watson recapitulates the chief propositions sought to be established.

i. Very many cases of bronchial asthma have their origin in laryngeal disease; that some remain for a variable period, as a spasmodic affection of the glottidean muscles, and that in all cases of the disease in question, although the bronchi have long been affected, the chief contraction still occurs in the larynx.

ii. If this contraction at the glottis be in any way overcome, that of the smaller bronchi either simultaneously or speedily relaxes.

iii. The usual remedies employed in spasmodic asthma are either directed against the complications of the disease, and not against its proximate cause, or have been found in practice incapable of accomplishing its removal. The latter are therefore useless, and the former unfit to fulfil the indication referred to above.

iv. This indication may be answered more or less perfectly in different cases, by the application of a solution of caustic of moderate strength (gr. xv., or ᶒi to ᶒi) to the glottis, which is the organ chiefly affected.

v. Cardiac asthma, as it is called, does not usually depend proximately on simple spasmodic contraction of the bronchial tubes, but rather on vesicular emphysema. Cases of this kind are therefore unfit for topical treatment.

vi. Electricity passed in gentle currents, as much as possible along the bronchial tubes, may be found to diminish their contractility; and repeated small doses of strychnia may co-operate with the other means of treatment, probably by withdrawing the nervous energy to other parts at a distance from the affected air-tubes.

TREATMENT OF ECZEMA.

The following is an abstract of an article by M. DEVERGIE, on the treatment of eczema, published in the *Journal de Médecine et de Chirurgie Pratiques* for May 1853. It is extracted from a work which he is about to publish on Diseases of the Skin.

The treatment of eczema ought to be local and general. regard must be paid to the acute, stationary, or decreasing stages of the disease; to its chronic form; to its causes; to the modifications which it may present, according to the part affected, and the age of the patient.

Acute Stage. In all cases of acute eczema, the general health must first be attended to. In some cases, where plethora is strongly marked, it may be necessary either to employ general blood-letting, or to apply leeches to the anus; and this is especially necessary in the spring. As internal remedies, refreshing acidulated drinks must be used, and solid food should be very sparingly used. This treatment must be continued during the whole of the acute stage. When there is much redness, heat, and smarting, M. Devergie employs, with much benefit, irrigations of water, at first lukewarm, then cold, for an hour or an hour and a half daily. The following is the method of applying the irrigations. A vessel of water is placed two feet above the part affected; with the vessel is connected a spout or a wooden tube, to which is fastened a band, divided into two at the lower part. The limb (a leg, for example) is placed horizontally on a waxed cloth disposed in the form of a gutter, so that the water may run off. The two ends of the band are placed one at the upper the other at the lower part of the leg; the tap is turned a little, and the water flows over the part. Under this treatment, the inflammation rapidly diminishes, and the eczema passes, in a few days, from the acute to the stationary stage. This treatment, however, can only be employed in summer, and in subjects in good health, and in whom the effects of cold are

not to be feared. The temperature of the water, and the duration of the application, can be modified as circumstances may require.

With regard to permanent local remedies, some cases of eczema in the acute stage will be found aggravated by aqueous emollient applications, while they receive benefit from pulverulent applications. Poultices, even under the most favourable circumstances, may remarkably increase the intensity and the extent of inflammation; while powdered starch may cause it to diminish rapidly. Other cases will not bear ointments; while they will be benefited by liquid emollients or resolvents, such as compresses wetted with elder-flower or marsh-mallow water, poultices of potato-starch (linseed-meal poultices are not well borne), sifted starch applied in a thin layer, and general emollient baths.

With the above remedies laxatives may be combined.

Stationary Period. The emollient treatment must be continued for some days, until the desquamated cuticle is removed, and in this period the general treatment of the predisposing cause must be commenced. If the patient be of a lymphatic temperament, sulphur, iron, and bitters must be given. If there be gastro-intestinal irritation, or suppressing of some habitual discharge, the proper remedies must be applied.

Of all general remedies, iodide of sulphur, sulphur, elm-bark, and arsenic, are the most efficacious. Iodide of sulphur was first used by Dr. Escobar, a Spanish physician. M. Devergie often administers it in doses of from three quarters of a grain to a grain and a half daily. This substance is readily decomposed by exposure to air; hence M. Devergie recommends it to be formed into pills. He first gives a pill night and morning in a cup of bitter infusion, increasing the dose by one pill every six days, until four pills are given daily.

The treatment by elm-bark has been abandoned for fifty years, although it once enjoyed considerable reputation. M. Devergie gives the elm-bark in the form of syrup, of which a dessert spoonful is taken morning and evening: the dose is increased every three days by a spoonful, so that at length three spoonfuls are taken in the morning and three in the evening. This remedy should be continued for six weeks or two months. Its efficacy probably depends on the large quantity of tannin present.

Arsenic is administered in the same forms as in squamous affections in general.

Period of Retrogression. There are here two special indications: to apply resolvents to the eczema, and to administer purgatives. In the winter, M. Devergie gives a mild purgative of Seidlitz powder twice a week. He prefers salines, because castor-oil does not stimulate the mucous membrane, and drastics are liable to produce obstinate constipation.

When ointments are not borne in the acute stage, it is easy to substitute pulverulent applications; but this is more difficult in the diminishing stage. The only powders which can be used are those of oak-bark and of old wood. M. Devergie has several times attempted to combine with these alum and oxide of zinc, but has found irritation produced. In these cases, he finds benefit derived from lotions of vinegar and water, of alum, of acetate of lead, or of bichloride of mercury. Alum and subacetate of lead are generally prescribed in the proportion of one part in three hundred; corrosive sublimate in that of one in two thousand five hundred. The cloths with which they are applied must be renewed or washed, otherwise they become impregnated with the salts, and a strong solution is applied instead of a weak one.

Ointments, when tolerated, should contain substances to relieve and to put a stop to the itching. To fulfil the first of these indications, oxide of zinc, calamine, tannin, nitrate of bismuth, or acetate of lead, may be used; always adding camphor or chloroform as a sedative. The effect of chloroform in relieving itching is more marked, but less permanent, than that of camphor.

M. Devergie, with other practitioners, sometimes employs juniper-tar oil and tar in ointment. These are most useful in old cases of eczema, especially in the psoriasisiform variety.

When eczema follows a steadily diminishing progress, recovery is remarkably promoted by the use of juniper-tar oil (*huile de cade*). Three conditions are here important: 1. That the oil be pure; for oil distilled from tar is frequently sold in its place, and this, although beneficial, is less so than the juniper-tar oil. 2. It should be used only every three days. 3. It must be spread over the diseased surface, and wiped up immediately with dry cotton, so that the thinnest possible layer of oil may remain. If there is too much, it produces irritation.

This remedy should not be used except in the latter stages.

If applied at a more early period, it either cures or aggravates the disease; and, in the latter case, it changes a case which would have been cured in a few days into an obstinate chronic case.

M. Devergie says, that collodion impedes the exit of serosity, and produces swelling of the skin; the small amount of serum exuded becomes purulent; and the skin becomes more diseased. He has hence abandoned the use of this remedy.

When eczema is general, existing in the form of larger or smaller patches on different parts of the body, internal medication is essential. Emollient and resolvent baths, especially vapour baths, are important; and sometimes it is useful to employ alkaline or sulphur baths.

Nummulated eczema requires the same treatment; and towards the end it is generally necessary to touch the diseased surfaces with solution of nitrate of silver twice or three times, at intervals of four or five days. M. Devergie follows the same treatment in *eczema unguiculorum*, and in all cases of local eczema.

Eczema of the scalp occurs in very early age. It only requires cleanliness, and the use of lotions of elder-flowers, marshmallows, or linseed. The hair must not be cut; and poultices must be applied but rarely, and then for a very short time. When the eczema is diminishing, M. Devergie would give mild purgatives, and apply a blister to the arm. He regards the disease as a means of evacuation set up by nature, the intensity of which ought to be moderated, but not entirely checked.

In very obstinate cases, which are almost always confined to a very limited surface, M. Devergie observes, that quacks often succeed better than physicians, because they employ remedies which will produce stimulation of the affected parts; such as ointment of nitric-oxide of mercury, or of sulphate of copper; or alkaline lotions and frictions. M. Devergie has tried a remedy employed in Berlin, viz., friction with a strong solution of carbonate of potash. He finds, however, no advantage in this treatment over that with juniper-tar oil.

M. Devergie has found dextertine bandages highly useful, especially in varicose eczema. He treats eczematous ulcers of the leg by strapping from the foot to above the ulcer.

CASE OF DIPLOSIS AVENS SUCCESSFULLY TREATED.

The following case is related by Dr. F. L. KEYES, in the *American Journal of the Medical Sciences* for April.

C. W. C. P. called at Dr. Keyes's office on the 22nd January, 1851, complaining of excessive thirst, which had increased very much during the previous three months. He was obliged to drink frequently during the day, and to have a pail of water at his bedside during the night, which he usually drank before morning, without the least abatement of thirst. In other respects, he enjoyed perfect health. He had suffered from excessive thirst (though not to the same extent) for ten years. Medical treatment had failed.

Dr. Keyes, considering the thirst to depend upon a morbid condition of the stomach resembling gastrodynia, prescribed as follows:—

R Hydrarg. deut-iodidi gr. iv.
Potassii iodidi ℥j.
Aque destillatæ ʒj. M.

Fiat solutio cujus æger sum. ℞v. ter in die.

He was also desired to chew pieces of the root of the rhubarb, and to swallow the juice.

In a few days, the thirst became less urgent; and, before the medicine was nearly all taken, the patient considered himself well. Up to Dec. 27th, 1852 (the date of the author's paper), the patient had had no return of the complaint.

SURGERY.

CYSTIC SARCOMA OF THE MAMMA REMOVED BY OPERATION.

The following case is related by Dr. R. T. CORBETT, in No. 1 of the *Glasgow Medical Journal*.

CASE. The patient was a lady, aged 38, of spare habit and rather weakly constitution, and the mother of six children. Two years and five months previous to August 1852, after weaning a child, she was much troubled with milk in her breasts for two days, but could not be relieved of it, being on board of a ship. From that time she began to fall off in her health, and three

months afterwards, she accidentally discovered a tumour in her left breast, and became Dr. Corbett's patient. The tumour was then the size of a hen's egg, hard, the seat of slight pain, which was somewhat increased on pressure. It was situated at the fore part, and rather to the left side of the mamma; and was quite moveable. Supposing from these symptoms that it might be a simple chronic inflammatory or strumous tumour, he ordered cod-liver oil and fomentation. She went to the country, and remained eleven weeks, but did not follow his advice. At the request of some practitioner in the locality, the swelling was leached four times during that period. On her return, the tumour had acquired the size of a goose's egg, was still hard, unattached, and the seat occasionally, or after exertion, of slight shooting pain. She had quite recovered her general health.

Dr. Corbett now ordered her three grains of hydriodate of potass, in a wineglassful of decoction of sarsaparilla, three times daily. At this time, Dr. McFarlane was called in consultation, and he recommended tincture of iodine to be applied every second or third day, and the internal medicine to be continued. This was done, and persevered in for a month; when there being no improvement in the tumour, Dr. Corbett recommended equal parts of iodine and camphorated mercurial ointment to be rubbed over it twice daily, and continued the other medicine. This treatment was pursued for fifteen days; and fomentations and a teaspoonful of cod-liver oil three times daily, gradually increased to a tablespoonful, for a month, when the tumour was fully the size of a man's fist, hard and lobulated, attached to the mammary gland, which moved with it, but it had no adhesion to the pectoral muscle. It was still only slightly painful. The patient's general health was good. Dr. Corbett was urgent to remove the tumour by operation, but the patient went to Calcutta with her husband.

October 25th, 1851. She had returned from Calcutta, having been ten and a half months away. She was delivered of a son four weeks before her arrival, and recovered well; but she was very thin, and suckled the child with the diseased breast as much as with the healthy one. The tumour, by the time she left Calcutta, five months after leaving Glasgow, had enlarged to the size of a cocoa nut of nearly full growth; but by the time she reached Glasgow it had attained an immense size, the after progress of the disease having been much quicker than at the commencement. The integuments covering the breast were now much inflamed and traversed by many large veins, and she complained of unusual heat and slight pain in swelling, which were removed by cold water dressing. The surface was irregular, the skin being elevated in several places into considerable sized swellings, and thinned, where fluctuation could be felt. The tumour was very moveable and pendulous, requiring to be constantly well supported. The glands in the axilla were not affected. Dr. Lawrie was now consulted, who suggested that a valvular opening should be made where fluctuation was most distinct, as much fluid as possible drawn off, and the aperture then closed. Dr. Corbett punctured the tumour next day, and drew off an ounce of opaque glairy fluid. The breast was not the least reduced in size. Considering the disease to be cystic sarcoma, they recommended the removal of the mass, as soon as she had weaned her child, and had somewhat recruited her system. The patient gave up nursing about the middle of January last, after having suckled her child fully three and a half months, and her health improved much in consequence; but the tumour continued steadily to enlarge in all directions, except downwards.

June 21st, 1852. The patient's general health was reported pretty good, but she was very emaciated. Menstruation was regular. Pulse 76. The tongue clean; the bowels confined. Half an ounce of castor-oil was given, which acted next morning.

June 22nd, 1852. The patient having been put under the influence of chloroform, Dr. Corbett performed the operation with the assistance of Dr. Andrew Buchanan, and Mr. Parker. Two slightly curved incisions being made through the integuments, so as to include only a small section of them with the nipple, at right angles to the pectoral muscle, the tumour was completely removed; and allowing one pound for fluid lost from an incision afterwards made nearly through it, the whole mass and liquid contents must have weighed about eight pounds. The hæmorrhage was moderate; four vessels required ligatures, after which the wound was brought together by five stitches, and cold water dressing applied. There was no secondary bleeding. In the evening, warm water dressings were substituted, and continued for seven days. The stitches were not removed till the wound had united, which it did by the first

intention, and the patient recovered without any untoward circumstance occurring.

DESCRIPTION OF THE TUMOUR. The tumour was examined in a general way immediately after its removal. An incision made completely through it gave exit to a large quantity of fluid, of various colours and consistence. While making the section, the surgeons repeatedly came upon considerable collections of milk in the dilated tubes of the gland. The larger part of the tumour consisted of cysts, varying in size from the smallest point visible to the naked eye to that of a large plum, contained in larger cysts, and attached in many instances to their walls by bands passing from their extremities. These contained cysts were gelatinous-looking and transparent, and presented an appearance similar to tapioca thoroughly boiled in water. Many large cavities also existed throughout the tumour, containing numerous cysts suspended by pedicles. Towards the centre and lowest part, the mammary structure presented a fibrous texture, arising perhaps from pressure, caused by the diseased mass resting upon it while in a state of chronic inflammation. The following morbid appearances were found on more careful examination.

1st. Vascular, firm, fibrous tumours about the size of small plums, contained in large cavities, and having cysts growing from their surfaces; and innumerable clusters of the same in the surrounding structure, in many places resembling miniature bunches of grapes. 2nd. A very vascular fibrous tumour in a cavity, about the size of a large plum, enclosed in a strong capsule, and having a multitude of various sized cysts growing over its surface. These cysts had a delicate cellular tissue within them in which the fluid was collected, so that when punctured it took some time to ooze out. 3rd. Cauliflower excrescences contained in a large cavity, with a few of the milk follicles attached to its walls, dilated and filled with a creamy fluid. 4th. Spongy, vascular, and warty-looking tumours; some of these were very irregular in shape, some were soft, and others were fibrous. 5th. Numerous concrete pearly-looking bodies, varying in size from a small to a large pearl, were also observed.

Towards the lower and internal part of the tumour, the mammary gland was found free from disease, with the exception of increased solidity of structure. The openings of the milk-ducts were patent, and the tubes themselves healthy, with the exceptions mentioned.

Judging from the facts ascertained from the history of this tumour, and its dissection, Dr. Corbett believes that the disease commenced in the cellular tissue in front of the mammary gland, but beneath its fibrous envelope, and not in the ducts of the gland. The fact of large collections of milk having been found in the lactiferous tubes and in the milk follicles, seems to strengthen the opinion, that the mammary gland was the part which became last affected. These collections, in Dr. Corbett's opinion, could only be accounted for by the effect of pressure of a contiguous growth, seeing that the milk flowed very freely, even when the disease had advanced considerably, and became less free, only when the disease pressed on with increased rapidity.

In Sir Astley Cooper's work on the *Diseases of the Breast*, chap. III, on Hydatid Disease, case 3 resembles the one narrated in many particulars. In it, the tumour when first observed, was hard and moveable, and gradually became larger, till it measured two inches in diameter. Mr. Bransby Cooper removed the tumour, and when cut into, a single cyst containing fluid was opened, formed in the cellular membrane of the breast, and surrounded by a solid effusion of fibrine. In all probability, such was the structure of the tumour now described at its commencement; and had the swelling been removed at that time, the mammary gland might have been saved. Case 10 of Sir Astley's work is also of a similar character; but the original situation of the tumour, besides being sub-areolar, may be intra-glandular, or sub-glandular, in which latter circumstances the mammary gland must always be removed with the diseased mass. Mr. Birkett, in his work on *Diseases of the Breast*, says: "The anatomy of the new developments of this class presents an almost inexhaustible variety, at least in appearance. Cysts of every variety of size, blended with fibrous growths varying in the same way, cysts containing fluid only, cysts with fluid an intra-cystic growths, vascular and pendulous, very soft and gelatinous, in other instances of the most fibrous and solid nature, present themselves in different parts of one and the same tumour."

ENTRANCE OF AIR INTO THE SAPHENA VEIN DURING THE REMOVAL OF A TUMOUR CONNECTED WITH THE SARTORIUS MUSCLE.

Dr. J. MASON WARREN recently related to the Boston Society for Medical Improvement the following, as having occurred when he was removing a tumour incorporated with the Sartorius muscle, and spread out on its back.

When the tumour "was lifted up, in order that the dissection might be prosecuted underneath it, on cutting the Saphena vein where it pierces the fascia, a distinct sucking sound was heard, as of the air being pumped into the vein. The finger was immediately placed over the mouth of the vein, and the farther admission of air prevented. The pulse remained for some time quite slow, and the patient did not revive from the effects of ether, the dose of which had been small, as readily as is usual."

Several cases of the same description have been published by Nysten, Amussat, and Dr. Cormack. Vide *London Journal of Medicine*, vol. ii. for 1850, p. 928, and Dr. Cormack's Thesis, Edinburgh: 1837.

CASE OF EXCISION OF THE HEAD OF THE FEMUR.

In No. I of the *Glasgow Medical Journal*, Dr. M. S. BUCHANAN thus relates and comments upon a case of this description.

Although the head of the femur was successfully removed by Mr. A. White, of Westminster Hospital, in the year 1831, the operation found no advocates, till Mr. Fergusson revived and performed it in several cases with the best results. Within the last five or six years it has been practised by other surgeons, and it may now be ranked among the established operations of surgery. Hitherto it has only been had recourse to in those more advanced cases of morbus coxarius, in which the head of the bone had become dislocated on the dorsum of the ilium. In the following case of excision of the head and neck of the femur, performed by me in the infirmary with a very successful result, it will be remarked that there is a striking contrast to most of those on record, in the above respect, as well as in the age of the patient, his previous robust health, and the whole history of the case.

CASE. James Downie, aged 41, Irish, plasterer, was admitted into the Royal Infirmary, 2nd November, 1850. In September 1849, he became incapacitated for his employment, and was unable to walk without a stick. From that period, till admission into the surgical wards of the hospital, he had been under the care of several intelligent surgeons, by whose advice he was repeatedly cupped, blistered, and cauterized over the affected hip joint, and had calomel and opium till typhalism was induced; as also some other medicines, the nature of which cannot be ascertained.

On the 2nd of November, 1850, the appearances and symptoms were as follows:—Patient cannot walk without the aid of crutches, and while in the recumbent posture is obliged to lie on his back, being unable to rest on either side. The right leg is semiflexed on the thigh, and does not admit of extension, apparently from contraction of the hamstring muscles, induced in consequence of the limb having been long kept in that position, as the one in which he lay with greatest ease. The knee joint appears to be unaffected. There exists considerable fullness around the right hip joint, over the trochanter major, and down the thigh for about four inches. In this swelling, fluctuation is distinctly perceptible. Over the whole gluteal region of the affected side there is felt a constant pain, greatly aggravated by the slightest motion of the limb, or on impinging the head of the bone against the acetabulum. He also complains much of pain in the inner side of knee. Pulse 110, feeble. Tongue dry and foul. Great thirst. Bowels regular.

An incision was made into the lower portion of tumour, through which was evacuated a large quantity of sero-purulent fluid mixed with flakes of coagulated lymph. Head of thigh bone found to be in its normal position. Fomentations were applied. *Full diet. To have six ounces of wine.*

Nov. 20th. The abscess daily discharges a large quantity of pus, now of a healthy appearance. Appetite much improved. Thirst continues. On pressing the head of the bone against the acetabulum, crepitation is distinctly perceptible. Continue the wine, and let him have four ounces of whisky daily.

Dec. 12th. To-day, while the patient was under the influence of chloroform, the opening in communication with abscess was enlarged, and a careful examination made with finger and probe, when no opening into the joint could be detected.

pressure over the trochanter still elicits a gritty feel, seemingly in the seat of the acetabulum.

From this date to the 22nd, the medicines prescribed were sulphuric acid, quinine, and opium. During this period, he had perspiration and diarrhoea.

On the 22nd, a consultation of the medical officers of the hospital was held, and, after careful examination of the case, failing to detect symptoms of other disease, it was recommended that the operation of excision of the head of the femur should be performed, as the only means by which life could be prolonged. The nature and extreme danger of the operation having been explained to the patient, he urgently requested its immediate performance, saying he would take his chance, small as it was, rather than endure any longer the excruciating agony he had been constantly suffering for some months back.

Dec. 23rd. The operation was performed in the following manner, the patient being under the influence of chloroform. Having been placed on the table on his left side, an incision to the extent of six inches was made perpendicularly over the dorsum of the ilium, in continuation with that previously made below the trochanter major, through the gluteus medius and minimus. A transverse one, forming the letter 'T', was then made, extending from anterior edge of pyriformis muscle to a line drawn from anterior superior spine of the ileum downwards. On exposing the joint, the capsular ligament was found entire, with the exception of a small portion of its inferior border, which was perforated by ulceration. The capsule being incised, the head of the bone was with care disarticulated, and made to project out of the wound by crossing the leg over its fellow. The head of the bone was found completely denuded of cartilage, and, along with the greater part of the neck, in a carious state. The section was made at the root of the great trochanter by means of a common saw, and the diseased bone removed. The apex of the trochanter major, being found in a carious condition, was also removed by the cutting pliers. The shaft of the femur below the trochanter was sound. The acetabulum was completely denuded of cartilage, and rough; the cotyloid and round ligaments were gone, ulceration having extended to the above parts. The edge of the cavity, which was carious, was removed by the forceps. No vessels requiring ligature, the lips of the wound were approximated at once by means of stitches and adhesive plaster, over which was applied the usual dressing supported by a bandage. The operation was completed in a quarter of an hour. About three ounces of blood were lost, and at no time did the pulse flag, although the patient was perfectly unconscious during its performance.

Dec. 25th. Progresses favourably. No return of the diarrhoea since the operation. Pulse 100, firmer. Appetite improved.

Dec. 29th. The stitches were to-day removed. The wound cicatrizes rapidly. The discharge is diminished, and more healthy. Sleeps well. Pulse 84, of good strength. Perspiration greatly diminished. Says he feels no pain in the seat of former disease, and, except at time of dressing, or in attempting to move limb, is quite easy. Omit brandy and quinine. Six ounces of wine daily. Two grains of opium three times a-day.

Dec. 31st. Continues to improve daily. With the exception of a small opening, where the perpendicular incision meets transverse, immediately below the trochanter major, the wound has united, and healed kindly underneath. The posterior edge of the trochanter major is slightly projecting through the lower opening already alluded to, and feels rough; but, on introducing the probe, the bone is found to be sound underneath. Pulse firmer. Two grains of opium at bed-time only. Continue wine.

January 2nd, 1851. Yesterday, towards evening, bowels became relaxed, and during the night he had four loose stools; but, by the administration of four grains of powdered opium in a starch injection, the diarrhoea was checked. He had taken during the day a larger quantity of soup than usual. Has taken a beef-steak to-day, instead of soup, with relish. The projecting portion of the trochanter is nearly covered with healthy granulations. A Probe introduced into the opening in the wound communicating with the acetabulum, discovers the surrounding parts in a healthy state, and only about the size of a shilling of the inferior edge of the cotyloid cavity is felt rough.

Jan. 11th. Has continued to improve since last report. The acetabulum is covered now with healthy granulations, with the exception of a small portion about half an inch in circumference, which the probe detects rough. The trochanter major is also covered completely with healthy granulations, over which cicatrization advances rapidly. Can now turn himself with ease round upon back, from left side, without experiencing the least pain.

Jan. 21st. Discharge being so small, wound has been

dressed only every second day since last report. The opening in communication with the cotyloid cavity, and through which the pus escapes, is now so small as hardly to admit the passage of a quill; and a probe introduced into this fails to detect any carious bone, healthy granulations having filled up whole of the acetabulum and surrounding parts. Superficial ulceration over the seat of incision and the trochanter major is almost completely cicatrized. On examination of the knee-joint, flexion and extension can be performed without pain; but on continuing extension, the hamstring muscles resist, and prevent the limb from being straightened.

Jan. 24th. These last three days, appetite has rather failed. Is troubled with acid eructations, which last symptom was removed yesterday by the administration of one drachm of Gregory's mixture. Ulceration over the seat of former incisions is completely cicatrized; the opening already mentioned, now about the size of a crow-quill, alone existing. From this a small quantity of healthy pus is daily discharged. Motion of the femur on the os innominatum can be accomplished to a considerable extent without pain. The whole cavity of the acetabulum is found to be filled up with osseous plasma and healthy granulations. Pressure on the dorsum ilii, and all around spot where disease existed, causes no uneasiness. In consequence of his long confinement to the hospital, the wards of which have been of late much crowded, his general health has suffered slightly; he was removed to the country by railway, and he stood the journey very well.

After this time, Dr. Buchanan visited him weekly, and found him progressing as favourably as could be desired, acquiring new strength, his appetite good, and in every respect feeling comfortable, and in good health. About two months after leaving for the country, he was seized with an attack of dysentery, having in the interval enjoyed great ease and freedom from pain. This affection, acting on a constitution already weakened by protracted suffering, speedily reduced him, and in the course of two or three days he died.

AUTOPSY. The wound was almost entirely healed up, a small opening admitting a probe alone remaining open. The whole course of the incision underneath was completely consolidated. The cut surfaces of the neck of the femur and great trochanter were quite sound, being coated with a cartilaginous incrustation. The circumference of the acetabulum, from which the edges had been removed, was studded with spicula of new bone, showing the progress which nature had already made towards a cure. The acetabulum was filled up with granulations, but in some points was still rough, the reparative process having not yet extended over the whole seat of disease. At the upper part of the cavity, there was a small isolated piece of rough and porous bone, loose, and evidently in the course of being discharged, piece by piece. Around this, the bone was rough, but not spongy; while other parts were solid and smooth.

Dr. Buchanan makes a number of interesting remarks upon excision of the head of the femur, in the course of which he states that his case will be found to differ from all others previously reported, in the following particulars:—

First. The capsular ligament was found entire, with the exception of a small opening at its inferior border, from which the pus made its escape.

Second. The head of the femur was consequently found in its normal position.

Third. Although the acetabulum was diseased, still only a part was removed; and yet a successful result followed.

Fourth. The advanced age of the patient; most of those operated upon by Messrs. Fergusson, Smith, and Norman, having been under twenty, some of them in childhood.

Lastly. Dislocation of the head of the femur has been regarded as another indispensable requisite for the performance of its excision, as, till that event occur, a cure by ankylosis may occur.

MIDWIFERY AND DISEASES OF WOMEN.

DR. G. HAMILTON ON THE USE OF THE FORCEPS IN TEDIOUS LABOURS.

Among the original communications in the *British and Foreign Medico-Chirurgical Review* for April 1853 is one by Dr. G. HAMILTON, of Falkirk, on the mortality from the use of the forceps in tedious labours. His object is to advocate the employment of this instrument much more frequently than is usually inculcated in the precepts of obstetric writers, or than is generally believed to be necessary or justifiable.

Dr. Hamilton says, that he first derived his notions of the

advantage of more frequently using the forceps from the late Dr. Reid of Edinburgh; and that he believes that this doctrine has been gaining ground among intelligent practitioners. A recent notice of Dr. Murphy's work on "Obstetric Medicine," in the *British and For. Med.-Chir. Review* for last October, has, to his disappointment, shown him that a very different line of practice is still advocated. He proposes to compare the statistics as furnished in the review, with those of three hundred cases of labour attended by himself.

The general conclusions from the statistical facts collected by Dr. Murphy are: "1. That in the forceps deliveries occurring in 78,892 midwifery cases in the hands of British, French, and German practitioners, nearly one in every four of the children was still-born. 2. That in protracted labours, 'so far as the children are concerned, the proportion still-born is very much the same, whether the forceps be employed or not; the difference, if any, being in favour of leaving these cases to nature'. 3. That the use of instruments is to be discountenanced in all but exceptional cases of this kind, in which the habit of the patient is too feeble to admit of her enduring a protracted labour without risk of exhaustion'. 4. That Ramsbotham employed the forceps once in 729 cases, Joseph Clarke once in 742, Collins once in 684, Kilian once in 78, Carus once in 14, Siebold once in 9; and 'Dr. Murphy's recommendation is, to employ them only in cases of positive arrest', unless dangerous constitutional symptoms are present."

Dr. Hamilton next gives the results of his own practice in three hundred cases of labour, among a generally robust and healthy population, composed partly of the upper and middle classes, and partly of the agricultural and working classes. The deductions which he afterwards makes are supported by a similar practice, extending to at least a thousand cases.

1. There were 306 children, five of the labours having yielded twins. Of these, eight were dead at birth; five being putrid, and one having been destroyed in a case of placental presentation. Of the other two, one died before the labour began; the other was a case of breech-presentation, in which much force was required to deliver the head. Setting aside, therefore, the first seven cases, the mortality to the children at birth was 1 in 298.

2. In the 300 cases, the forceps were used forty-one times—rather less than 1 in 7; and all the children were born alive.

3. Of the whole children born alive, ten died within about a week; six having been delivered naturally and easily, and four with forceps. Of the former, two, and of the latter one, were premature; so that, of children who might have lived, 4 in 256, or 1 in 64, died within a week when the labour was natural; and 3 in 41, or about 1 in 14, when the forceps were used.

4. The forceps were used chiefly in first labours, and in females who had a particular form of pelvis. They were used ten times in primiparae, and seventeen times among seven other females. Deducting these twenty-seven, we have the forceps used in one case in twenty-one.

5. The labour process proved fatal to three mothers, or 1 in 100 in all; of these, one had a natural labour, and two were delivered by forceps. The mortality to mothers was thus 1 in 259 in the former class, and about 1 in 20 in the latter.

6. In none of the cases did any local injury to the parts arise from the use of the forceps.

Dr. Hamilton hence concludes, that the mortality to the children from the labour-process was in his practice 1 in 298; while Dr. Clay gives the mortality in the Dublin Lying-in Hospital, in 156,000 cases, as 1 in 17; Dr. Simpson, in the Edinburgh Maternity Hospital, as 64 in 1417, or 1 in 22; Dr. Lawrence, of Montrose, as 1 in 46. The mortality from the use of the forceps also varies from one in four or five to two in three; while Dr. Hamilton states that, in his practice, forty-one consecutive forceps-cases have occurred without a single death. The mortality to the mothers he has also found for the most part smaller than in most of the tables which he has consulted. He suggests, that perhaps this may be accounted for by differences in the circumstances, and in the treatment employed; for, instead of the crowded, debilitated, and often ricketty population of large towns, from which these statistics are mostly drawn, his cases have occurred in a robust and healthy population, free from puerperal epidemics.

The author divides labour into two stages; the first ending when the os uteri has been dilated to about double the size of a crown-piece. In the first stage, he does not interfere as a general rule; but in protracted cases, if the pains are not very urgent, he allows the labour to go on for twelve, twenty-four, or more hours; sometimes giving an opiate. He believes that the safety attending protraction of this stage invalidates Dr.

Simpson's statistical deduction, that the ratio of mortality increases with the length of labour.

With the second stage of labour, according to Dr. Hamilton, commences the great danger from delay; and hence he endeavours to shorten it. He first endeavours to clear the head from the uterus; and for this purpose he ruptures the membranes, if this has not already occurred; and supports the anterior and lateral parts of the os uteri with his two forefingers during the pains, which are thus increased in force and efficiency, till the uterus slips over the head. When necessary, he introduces the whole hand, and pushes up the uterus all round the head. In two or three of the forceps cases, he did not succeed in this procedure, although the head got pretty far down in the pelvis: in these, he applied the instruments within the neck of the uterus, using the two forefingers of the left hand for pressing the uterus upwards as the forceps brought the head down.

If the ear is exactly opposite the symphysis pubis, or slightly to either side in the wrong direction for making the turn into the hollow of the sacrum, he generally soon applies the forceps, if little or no change occurs in the position of the ear. When the ear does not indicate a revolution of the head, he is convinced the labour will be tedious; and within from an hour to two hours, he applies the forceps. When the broad transverse form of the pelvis is decided, as in flat or squat-made females, where the ear is on the wrong side, where the pains are severe but no progress is made, where the mother is a primipara, or where the first half of labour has been tedious, he interferes at an early period. He states, that he has not been able to turn the head with the fingers or hand, as has been advised by some authors. Of the forty-one forceps cases, he says that at least eight-tenths had the head in the transverse position; and the rectification of this position is one of the endeavours which he has in view. In the other cases, the child was larger, or the pelvis smaller, than usual; or the pains were deficient.

Dr. Hamilton's practice has extended to one thousand cases; and he says that he "goes back to his three hundred and eighteenth labour, and forty-fourth forceps case, before he meets with a still-born child"; and this was a case in which perforation was necessary.

He thinks that "it clearly follows, from the statements made, that it is, in such instances as have been referred to, the delay in the second half of labour, and not the application of the forceps, which is usually fatal to the child"; and he infers "that instruments should be used much sooner and much oftener than is generally done".

In six of the forceps cases, chloroform was given: in five of these, the deliveries were easy; but, in the other, the chloroform decreased the strength of the pains, and prevented the head from being brought by them within the reach of the forceps. Ergot was used only three or four times in the 300 labours.

The forceps used are those invented by Dr. Ziegler of Edinburgh; they are thirteen inches in length. The blades are of equal length, and strength.

[This is an interesting paper: but we cannot sanction the doctrines which it teaches.—EDITOR.]

ULCERATION OF THE CERVIX UTERI TREATED BY THE APPLICATION OF COLLODION.

The *Bulletin Générale de Thérapeutique* for January 15th, states that M. ARAN employs collodion with success in certain cases of ulceration of the neck of the uterus, especially those which depend on, or are kept up by, the friction of the vagina against the cervix, directed either forwards or backwards. An illustrative case is related of a woman, aged 29, who was admitted into the Hôpital de la Pitié, who had for two years suffered from headache, dyspepsia, leucorrhœa, and dragging pains in the lumbar and hypogastric regions. These symptoms had for six months become much more severe. On examination, M. Aran found the uterus in a state of anteversion; the neck was large and extensively ulcerated, principally at the posterior part, which was directed towards the hollow of the sacrum. Rest, slight cauterisation from time to time, with nitrate of silver, baths every two days, poultices, enemata, and emollient injections, were tried for more than three months without any marked result. When lying down, the patient did not suffer; when erect she was troubled with dragging sensations in the loins and hypogastrium. M. Aran applied collodion over the cervix, by means of a brush. The patient only felt a slight burning sensation when the speculum was removed. Three days afterwards, most of the collodion had run off, and the ulcer, which could be seen through it, appeared to be rapidly progressing towards cicatrisation. The application of collodion was repeated three times within a month; and at the

end of this period, cicatrization was nearly complete. At the same time, the dragging in the loins and the pains in the stomach had diminished, and the leucorrhœa had completely disappeared. The patient walked without pain or difficulty; her general health seemed excellent; and, with the exception of a little weakness in the loins, and some heaviness of the head, she felt quite well.

This is satisfactory enough as far as it goes; but has the cure been permanent? On this subject we have some fears; for it is stated that "the anteversion is still much marked"; and in this case the tilting of the cervix backwards, and the consequent friction of its posterior lip against the vaginal wall, may reproduce the ulceration.

DRY-CUPPING A SUBSTITUTE FOR ERGOT.

The *Charleston Medical Journal and Review* for January 1853, quotes a paper on this subject from the *Nashville Journ. of Med. and Surg.*, of which we give an abstract.

Dr. WASHINGTON has recently discovered that dry-cupping, applied to the lowest part of the sacrum, produces dilatation of the os uteri; and, applied higher up, contraction of the uterus.

In a case, where the pains had endured fourteen hours without producing any perceptible effect, in consequence of rigidity of the os uteri, Dr. Washington applied a dry-cup as low down on the sacrum as possible, so as to cover the origin of the nerves to the os uteri. Complete relaxation ensued; at the next pain, the head descended to the outlet; and at the second pain the patient was safely delivered; and that in less than ten minutes from the application of the cups. In tedious labour, the cup should be applied first to the lowest point of the sacrum, and if, in the course of ten or fifteen minutes, the patient is not delivered, another should be applied higher up, so as to cause the uterus to contract. *The lower one should always be on when the upper one is applied, so as to insure relaxation of the os uteri when the pains come on.*

In retained placenta, the cups are to be applied higher up, so as to cause the uterus to contract at once, the relaxation of the os uteri being always sufficient after the fœtus has passed.

When ergot is administered, the woman is delivered by main force, without any relaxation except that produced by the most fearful pains. By dry-cupping, two or three pains are sufficient, and the amount of suffering is not more than ordinary.

LITZMANN ON OVARIAN TUMOURS AS A CAUSE OF DIFFICULT LABOUR.

The *Deutsche Klinik*, for 1852, Nos. 38, 40, and 42, contains an article by Professor LITZMANN, of Kiel, on the influence of ovarian tumours in producing difficult labour. The following is an abstract of this interesting paper.

It is a recognized fact, that conception is no more prevented by the degeneration than it is by the extirpation of one of the ovaries. Pregnancy seems in many cases to induce a more rapid growth of the ovarian tumour: this is especially true with reference to cystous and cancerous tumours. Fatty growths, as a rule, are not affected by gestation. Gestation is also prematurely interrupted by ovarian tumours; partly from their mechanical pressure on the uterus, and partly, (especially in cancer,) by the setting up of a profound disturbance of nutrition and innervation. Small ovarian tumours, which entirely or partially sink into the pelvis, are apt, from their pressure, to bring about abortion at an early period of pregnancy.

If pregnancy reaches its full period, the labour may end naturally, both as regards mother and child; but more frequently ovarian tumours give rise to impediments endangering the life of the mother as well as of the child. To thirty-one cases collected by Puchelt, jun., Dr. Litzmann has added fifteen from various sources, and one case described by himself—making in all forty-seven cases, in which labour was impeded by ovarian disease. Of these cases, in twenty-five the diagnosis of ovarian tumour was confirmed by section or by puncture: four of the tumours were simple cysts, three were compound, twelve were fatty cysts, and six were scirrhus growths. In the other twenty-two cases, the relation of the tumour to the ovary is not pointed out. The diagnosis during life is by no means easy, and can for the most part be considered only as more or less probable. In general, large tumours, lying entirely or partially over the entrance of the pelvis, are readily distinguished; while in small tumours, occupying the posterior part of the pelvic cavity, the diagnosis from other tumours which occur in this part is difficult. These ovarian tumours are always found in the space between the vagina and the rectum. The principal signs by which they can be distinguished from fibroid cystic growths,

etc., between the vagina and rectum, are their gradual direction from the synchondrosis on one side toward the middle of the hollow of the sacrum, and the possibility of pushing them more or less easily above the entrance into the pelvis. But commonly the tumour is first detected only when it is entirely in the pelvis, and when its reposition during labour is not unfrequently prevented by the pressure of the gravid uterus or by adhesions. Fibrous and scirrhus growths from the inner surface are distinguished by their not easily mistaken place of origin, as proved on examination *per rectum*. More difficult, and often even impossible, is the diagnosis from other tumours in the recto-vaginal space, as cysts of the uterine ligaments, or of the Fallopian tubes, or tumours of the posterior wall of the uterus. As the latter are found very rarely to produce hindrance to labour, the detection of a tumour in doubtful cases affords a strong suspicion that it is ovarian. It is of especial importance to discover whether the tumour be solid, or a cyst, whose contents may be let out by puncture or incision. Fluctuation, if present in the least degree, will be best detected by examining the tumour simultaneously through the vagina and rectum in the intervals of the pains. The smoother and more equally developed the swelling is, the greater is the probability of its being a cyst.

Ovarian tumours are most dangerous to the progress of labour, when they are wedged more or less deeply in the pelvis: but tumours lying above or upon the entrance into the pelvis may, in certain circumstances, produce a great mechanical impediment.

The forty-seven cases related contain a notice of the progress of, in all, fifty-six labours. In ten, natural delivery took place, mostly after tedious labour and severe pains. In two cases natural labour was assisted by the death and putrefaction of the child, in another by the pliability of a hydrocephalic head. One child was born alive; the reports do not state the fate of the others. Four of the mothers died.

In seven cases, the tumour was pushed above the pelvic entrance. In three of these cases, turning was performed; in one, the forceps were applied; and in three, the labour proceeded naturally after the reposition of the tumours. Two of the children were still-born; and of five born alive, two soon died. One of the mothers died.

In nine cases, puncture or incision of the tumour was performed; once through the abdominal parietes; twice through the rectum; and in all the other cases through the vagina; always with the effect of diminishing its volume. In three cases, labour proceeded naturally; in three, perforation and extraction had to be performed; in one case, turning was necessary; and in one, the forceps were applied. Only one child was born alive; and five of the mothers died.

The forceps were applied in altogether eleven cases: once after puncture; once after reposition of the tumour; once to extract the head in a case of turning; and in one case they were ineffectual, and delivery had to be effected by embryotomy. In all the other cases, the forceps were the only instrumental means employed; in these, two of the children were still-born, and four of the mothers died.

Turning was performed in eight cases; in three after reposition of the tumour, and in one after puncture. The results to the life of the mother and of the child are not stated with sufficient accuracy. Extraction in foot-presentation was performed in three cases; all the children were dead.

Embryotomy was performed in seventeen cases; in four after puncture (in which three of the mothers died); and in one case in artificial premature labour; of the remaining twelve cases, five were fatal to the mothers.

Premature labour was induced in two cases.

Of the whole, seven children were born alive, thirty-five were still-born, while there is no account of fifteen; of the mothers, thirty-two recovered, and twenty-four died.

In the treatment of these cases, a principal rule is not to delay operative interference too long, as it is very rarely that a favourable termination to the labour, as regards both mother and child, is to be hoped for from the powers of nature. By delay the life of the child is almost always sacrificed: its skull usually undergoing pressure between the tumour and the wall of the pelvis, as in a case of narrow pelvis. As regards the mother, besides the tediousness of the labour, the unavoidable bruising of the tumour and of the weaker parts of the pelvis is to be feared; and when the pains are violent, there is risk of rupture of the uterus or of the tumour. The result of every operation, to which recourse has been had at a late period, is doubtful.

During labour, we must first attempt to push the tumour, *per vaginam* or *per anum*, above the pelvic entrance. The most convenient period for this appears to be immediately after the rup-

ture of the membranes, or as soon as more active pains have set in. If reposition is not possible, no time must be lost in ascertaining whether it is possible to diminish the size of the tumour by evacuation of its contents. This is best performed by puncture through the vagina with a curved trocar; and if the contents are too firm, the aperture may be enlarged by incision. If this operation is ineffectual, the choice lies between embryotomy and the Cæsarean section. Extirpation of the tumour during labour seems to have not yet been attempted. No help can be expected from the forceps or from turning, unless the size of the tumour have been previously reduced. With regard to the indication of premature labour, Dr. Litzmann thinks it but rarely indicated; as the narrowing of the pelvis by ovarian tumours is mostly so remarkable, that without previous reposition, a living child cannot be delivered even prematurely. He says that it should be performed only in those cases in which there is a narrow pelvis as well as an ovarian tumour.

ASSOCIATION INTELLIGENCE.

PROVINCIAL MEDICAL & SURGICAL ASSOCIATION.

ANNIVERSARY MEETING, 1853.

The members and friends of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION are informed that the twenty-first anniversary of the Association will be holden at Swansea, on Wednesday, the 10th, and Thursday, the 11th of August next.

The Council of the Association will meet at seven o'clock on Tuesday evening, August 9th, by permission of the Worshipful the Mayor of Swansea, in the Guildhall.

The First General Meeting of the Association will be holden in the Guildhall, on Wednesday morning, August 10th, at ten o'clock, when the President, JAMES ADEY OGLE, M.D., F.R.S., will take the chair, and afterwards resign it to GEORGE GWYNNE BRID, M.D., President-elect.

The Report of the Council will then be read by the Secretary, after which Augustin Prichard, Esq., Lecturer on Descriptive and Surgical Anatomy at the Medical School, Bristol, will deliver the "Address in Surgery". Cases and communications will also be read, and other business transacted.

At one o'clock the meeting will adjourn.

The meeting will resume its sitting at two P.M., when the Report of the Benevolent Fund will be presented, after which cases or short communications may be read.

At five o'clock the meeting will adjourn.

Conversations. The President and Local Committee have proposed to receive the members of the Association at eight o'clock in the evening, in the National School-rooms.

On Thursday morning, the members of the Association and their friends will breakfast together, at half-past eight o'clock. Tickets two shillings and sixpence each.

At twelve o'clock the same day, a General Meeting of the members will be holden at the Guildhall, when the "Address in Medicine" will be delivered by Dr. C. Radclyffe Hall, M.D., Torquay, Devon, and cases and other communications read.

On the evening of the same day, the members and their friends will dine together at six o'clock. Tickets one guinea each, including wine and every expense.

Due notice will be given of the places at which the breakfast and dinner parties will assemble.

The principal hotels are the Mackworth Arms, the Castle, the Commercial Inn, the Bush, the Cameron Arms, and the King's Head.

The Local Committee will gladly attend to any application for securing beds and lodgings at a reasonable charge.

The Local Committee consists of the following gentlemen:—

Council of the South Wales Branch.

Dr. Bird, President-Elect.
Dr. Morris, President-Elect of the South Wales Branch.
Dr. Howell, Swansea.
J. Brewer, Esq., Newport.
E. Davies, Esq., Merthyr.
Dr. Lawrence, Carmarthen.
Dr. Vachell, Cardiff.

J. D. Brown, Esq., Haverfordwest.
E. Evans, Esq., Cardiff.
W. P. Evans, Esq., Swansea.
F. C. Batt, Esq., Abergavenny.
Dr. Sylvester, Cowbridge.
T. French, Esq., Neath.
W. H. Michael, Hon. Secretary.

Other Members of Committee.

J. S. White, Esq., Dowlais.
W. Rowland, Esq., Swansea.
Dr. Williams, Swansea.
T. A. Essery, Esq., Swansea.
J. G. Hall, Esq., Swansea.
H. L. Prichard, Esq., Taibach.
Dr. T. J. Whitty, Briton Ferry.
J. Cook, Esq., Morriston.

Members and visitors arriving at Swansea, are requested to apply at the Guildhall on the Wednesday morning, when, on registering their names, they will be supplied with tickets of admission to the meetings of the Association, with such local information as their convenience or necessities may require.

Gentlemen who purpose to join the breakfast or dinner parties are requested to make intimation of such intention to the Honorary Secretary, W. H. MICHAEL, Esq., Swansea, on or before Thursday, August 4th, that means may be adopted to secure suitable accommodation. Local circumstances render this arrangement indispensable. The Committee of Management therefore request that the members of the Association will kindly pay due attention to this request, otherwise great inconvenience and disappointment will certainly accrue, and very considerable expence be unnecessarily incurred.

The Secretary of the Association will be in attendance to receive the subscriptions and arrears from those who have not previously had an opportunity of paying them; and those members who do not attend the meeting, and wish to remit their subscriptions, may readily do so through friends who attend the meeting, or through their own bankers, to Messrs. Roberts and Co., London, for Messrs. Barwick and Co., Worcester, the bankers of the Association; or the same may be remitted by Post-office order to Sir Charles Hastings, or J. P. Sheppard, Esq., Worcester.

J. P. SHEPPARD, F.R.C.S.,

Secretary to the Association.

The objects of the Association will be much promoted by members making its advantages known among their medical friends and acquaintance. Gentlemen desirous of joining the Association are requested to apply to some member of the Council residing in their immediate neighbourhood; or where there is a Branch Association, to the Secretary of the Branch.

EDITOR'S LETTER BOX.

MORE EASY TO AMEND THAN TO OBTAIN A MEDICAL REFORM ACT.

LETTER TO THE EDITOR.

SIR,—It seems to me most injudicious in medical reformers to show lukewarmness or opposition to the present Medical Bill merely because it does not happen, in all respects, to suit their notions. I wish you would impress on our members that it is much easier to get an Act amended, than to get a Bill passed through Parliament for the first time; and that the hope of obtaining a measure which will never require to be amended, is utterly visionary, and ought to be discouraged.

I am, etc.,

A GENERAL PRACTITIONER.

London, May 17, 1853.

COMPULSORY VACCINATION.

LETTER FROM GEORGE KING, ESQ., TO THE EDITOR.

SIR,—I have read the compulsory Vaccination bill passed by the House of Lords, and I consider their lordships are deserving of the thanks of the country for this act of humanity and philanthropy. It is very clear that the small-pox prevention act of 1840 has not produced the effect intended, as this malignant and frightful disease is now raging in some parts of the country. I hope that in the Commons, by the assistance of the profession, the bill will be made more practicable, and much of the machinery removed. All that is required is, that every child should be vaccinated before a certain age; and that, if this has not been done, the parents or relations should be subject to a fine. If such an act as this were passed, and published by mayors of cities, parish officers, and others, parents would soon enough get their children vaccinated. They would not require a register to inform them of the consequences of their neglecting to have it done. Most people know that, if they rob or steal, they will be punished; and if they commit murder, the chances are that

they would be hanged; and they must also know that there is a law to enforce it. It has never yet, that I have ever heard of, been considered necessary to give parents a certificate to tell them that, if their children should ever rob, or steal, or commit murder, the law will be carried into effect against them.

Those that have had much to do with vaccinating have often wished that they were armed with some authority to enable them to contend with not only the prejudices of the lower classes, but the opposition and obstinacy of the educated portion of the community against their children being vaccinated. It is useless for the government to pass laws for the prevention of contagious and epidemic disease, and allow the rising generation to go unprotected from such a loathsome disease as the small-pox. We should expect and suppose that the laws of reason and good sense would compel persons to adopt vaccination; but it is a lamentable fact, they do not. It is this that renders compulsion, or some legal authority, absolutely necessary. We are not allowed to do each other any personal injury with impunity; neither ought any one, by their neglect, or through ignorance, prejudice, or apathy, be permitted to kill or injure their neighbour by propagating a malignant and pestilential disease; and there is much credit due to the nobleman who is endeavouring to put a stop to such a state of things; and, instead of our opposing him, as medical men and friends of humanity, we ought to advise with and aid him in his philanthropic and praiseworthy intentions—the extinction of small-pox: and I think this will be done if the compulsory bill is passed. The vaccination bill of 1840 is still to remain in force; therefore, the poor will be able to get their children vaccinated by those vaccinators appointed by the guardians; and the public will very soon find the ways and means to get their children done, when they find that they will be subject to a fine if it is not done before they are a certain age. Their being compelled to have their children vaccinated then, the only thing wanted will be the proof or the certificate that it has been done. This proof may be obtained without the establishment of any new office or officer. It is well known to the profession, that the clerks of the unions supply the union vaccinators with a certificate-book, in which they register all that are vaccinated by them now. If the Registrar-general of births and deaths were to send to every qualified medical practitioner a similar book, he could give to the parents of the child that he had vaccinated a certificate that the child had been effectually vaccinated: this certificate should be taken to the registrar of the subdistrict, to be registered in the same manner as is done in the registering the cause of death; and the registrar of the district to give the parties a certificate in return, as he does to the undertaker in case of death; and this certificate would show, or should be taken as legal proof, that the child had been vaccinated. All this might be done without any charge to the parents; the registrar to be paid by the clerks of the unions, in the same way as he is paid for registering births and deaths. Whether the fee for doing it should be sixpence or a shilling, I will leave the legislature to decide. To this plan I do not think the public or the profession would object. There is no union here with the poor-law guardians or the poor-law commissioners. Although the public would be by the compulsory vaccination act obliged to get their children vaccinated, they would be free to get it done by whom they pleased. There would, no doubt, be every facility offered them. I, like hundreds of others, vaccinate gratuitously, and shall continue to do so; and am willing to give the certificate to boot. For the registrar to give to the parents a certificate, when they call to register the birth of their child, as is recommended in the bill, to tell them that they must do what we should suppose duty and parental affection would prompt them to do, would be very annoying, and by many, I fear, would be considered an insult.

The great object that Lord Lyttelton seems to have in view is to get rid of small pox. I do not think that he is wedded to any particular plan of doing it; and we, instead of opposing him, ought to render him all the assistance we can in his benevolent endeavours. If we wish to get rid of one of the most contagious and frightful diseases that we have to contend with, we must support compulsory vaccination. I am, etc.,

GEO. KING.

Bath, May 20th, 1853.

[If Lord Lyttelton require the assistance of the profession, time must be granted. That is the point for which those who have most studied the vaccination question are now contending. Arguments on all sides can then be fairly stated and weighed. EDITOR.]

COMPULSORY VACCINATION.

LETTER FROM JAMES WILLIAMS, M.D., TO THE EDITOR.

SIR,—My experience for nearly ten years in a large poor law district, enables me to question many of the statements in the ASSOCIATION JOURNAL in regard to vaccination. I admit that we are miserably paid; still, on the other hand, I do conscientiously and positively assert that vaccination has been both skilfully and honestly performed, by a body of practitioners as well qualified as any in the united kingdom. (Vide Lord Lyttelton's speech, April 12th, Journal 15th.) To this assertion I also add my own testimony as to the readiness, on all occasions, with which *good lymph* is supplied by the National Vaccine Institution, whence I never have, in any one instance, experienced the least difficulty in obtaining it. Believing, therefore, with Lord Lyttelton that the principal obstacle to universal vaccination is the *ignorance and indifference* of the poor and uneducated; and further, while as an Englishman I would not renounce a title of my right to freedom of opinion, yet I perceive a decided contrast between *wholesome coercion for the benefit of the many*, and absolute tyranny for the advantage of the few. I therefore give my unswerving support to a compulsory medium of vaccination, without which I believe that universal vaccination cannot be attained.

I would ask two simple questions: Could such a compulsory measure as the one already before the country at all interfere with the right of the rich, by preventing them from employing their own private medical attendant? Or would it impose any hardship on the poor, by compelling them to seek the poor law medical officer, instead of his now being obliged to look after them for their own benefit, and even then meeting with difficulty—nay, often insult—in endeavouring to persuade them into a willing acceptance of the same?

Another point of argument occurs to me. Were public vaccinators to be appointed, in lieu of the poor law medical officer, for the vaccination of the poor, would it not unjustly deprive us of those extra fees intended (and contracted for) to make up the regular union salary? I am as anxious as any one that the new bill should be both just and practicable; yet believing you to have somewhat misunderstood the measure, I have felt it my duty to present to the profession my thoughts on what I conceive might be a great and important advance in sanitary reform.

In the discussion on vaccination at the Metropolitan Counties meeting last week, Dr. Cormack stated "that clause v specially provides that there is to be no remuneration legally due for the highly responsible and troublesome duties imposed by the act", *omitting the important words* at the end of the clause—"other than is provided by the first-rected act"; this act enabling boards of guardians to contract for the performance of vaccination."

Also, clause i was styled as absolutely ridiculous (?), which states, "that in all practicable cases, the vaccination is to be performed from the arm of a healthy child". This plan I have more frequently done than otherwise; and always, if practicable, give the parents the choice of the child's arm from which the lymph was to be taken. The latter part of the clause may be improved or omitted.

Upon a review of the whole subject, I cannot but conclude that the measure has been received in that bad spirit which has too often distinguished our profession when medical reform has been attempted by *non-professional statesmen*. Thus we have often lost the good we might have attained, by cooperating with and assisting such laudable efforts for the relief of suffering humanity. Why not forward suggestions for improvement, instead of condemning the measure wholesale?

I am, etc.,

JAMES WILLIAMS, M.D., M.R.C.S., & L.A.C.
Medical Officer of the Woburn Union.

THE ECONOMIC INSURANCE COMPANY.

LETTER FROM JOHN FRANKED, Esq., TO THE EDITOR.

SIR,—About a fortnight since, I received a letter from the "Economic Insurance Office", containing the usual questions relative to the health of a patient of mine, to which I replied by a note, stating that it should be attended to, on receiving the customary fee or a reference. I heard no more, until, a few days

* The entire Act as amended is reprinted at p. 424 of the number for May 13th. One shilling and sixpence is the legal fee per case. Some Boards of Guardians contract for sixpence a case. EDITOR.

afterwards, a medical practitioner from an adjoining town called on me, and in the course of conversation stated that he had been requested to see the same patient, and give an opinion on the life. I told him of my reply, and I understood that he was to be remunerated for his opinion. About a week after, I received another letter from the "Law Life Insurance Office", respecting the same patient, and gave a similar answer, when I received a communication from some solicitors in London, stating that my fee would be paid by them. I then waited on my patient, and found that, having a slight cough at the time of the neighbouring practitioner's visit, he had most likely given an unfavourable report, and the Economic Office had declined to assure, though it had a previous insurance on the same life; but as I was well acquainted with the patient, I could give a very favourable opinion, and I believe the life is now insured; therefore, in this instance, the Economic Office has lost an insurance for want of liberal conduct to the medical profession.

With reference to insurance offices generally, my own experience is, as a rule, that the old offices decline to remunerate medical men, or, at all events, remunerate their own officer only; but the younger offices invariably give a fee. Some offices, such as the "West of England", always refuse the fee; but if the insurance is a good one, they will pay the fee rather than lose the business; and I believe it only remains for medical men steadily to decline giving the opinion except on remuneration, and the difficulty will entirely cease.

Your publishing the names of companies which do, and which do not pay, enables medical men to lay the subject before patients, and to advise them to select those which act with equity.

I am, etc.,

JOHN PRAKKEED, M.R.C.S.E., and L.A.C.

Langport, Somerset, May 10th, 1853.

PHYSICIANS, SURGEONS, AND GENERAL PRACTITIONERS, BY NOT KEEPING THEIR RESPECTIVE PLACES, CAUSE HOSPITAL ABUSES.

LETTER TO THE EDITOR.

SIR,—Being connected with a metropolitan hospital, where large numbers of out-patients attend, I would add my testimony to the justice of many of your remarks upon hospital abuses. I for one should feel greatly obliged to you for suggesting an efficient remedy. The great mass of gratuitous patients are, as far as I know, of no advantage to the hospital surgeon. A few proper cases, carefully attended, would furnish him with much better means for clinical instruction.

As far as the profession is concerned, the great evil which has arisen appears to me to be, that the physician or surgeon and the general practitioner no longer maintain their respective positions in regard to each other. Many cases, which ought to be treated by the general practitioner, become hospital patients; and, on the other hand, many patients, who really ought to have the benefit of the opinion of a physician or surgeon, are kept away.

This is a subject which has two sides. It is manifestly to the advantage of both parties that a better understanding should prevail. An evil like that under consideration cannot be confined to one class of the profession.

With a better regulated system, and with increased mutual confidence, a large class of patients, who now consider that they have a right to seek hospital relief, would be attended by the general practitioner, and would be seen occasionally, either at the hospital or in private, by the physician or surgeon. The patient, under this system, would be better attended; the physician or surgeon's time would be saved; and the general practitioner would be remunerated.

I will conclude by furnishing you one example in illustration of the above remarks. A very few days ago, a well-dressed man came before me, with a great degree of independence, and with his hat on, wishing to be made an out-patient. The following dialogue ensued:—

"What is your business?"

"A grocer."

"Surely you are not a proper person to seek hospital relief?"

"My governor subscribes to the hospital, and I consider I have a right to apply."

"You must give my compliments to your governor, and inform him that you have no right whatever. The hospital is for the poor."

I am, etc.,

A SURGEON.

May 23rd, 1853.

NEWS AND TOPICS OF THE DAY.

THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION OF IRELAND. A society with the above name is about to be established in Ireland by means of a revival of the old Medical Association. We will notice this important movement at some length in an early number.

THE VACCINATION BILL. The Manchester Medico Ethical Association has presented to the House of Commons, through Mr. Bright, M.P., a petition in which they express their entire approbation of the principle of compulsory vaccination; but at the same time point out that several of the provisions of Lord Lyttelton's bill are defective in themselves, and oppressive to the medical profession. The clauses to which this remark is more particularly made to apply are, the appointment of stations not more than a mile from the furthest limit of the district; the vaccination from the arm being made compulsory; the reporting every exceptional instance to overseers or guardians; the vesting of power in the guardians to vacate the contract; the want of provision for supplying the medical officers with lymph; the onus of transmitting a duplicate of the certificate to the Registrar; and the inadequate remuneration of the medical officer.

The medical practitioners of Hull have addressed to Lord Lyttelton a memorial on the subject of his bill. They submit, that "the attempt to make vaccination compulsory will probably have a tendency to make a beneficial and salutary boon odious and unpopular, simply because it is compulsory and not voluntary; they would therefore suggest, that every facility should be given for extending the benefits of vaccination, but that the compulsory enactment of that operation should be confined to those children who may not possess the advantage of the protection of their natural guardians". They also protest against the amount of service required being at the maximum, while the rate of remuneration is at the minimum; and they suggest adequate remuneration as a necessary means for securing the efficient performance of vaccination. They also complain that no efficient means are provided for supplying an available supply of lymph from some central establishment. The clauses which make the vaccinators responsible to the guardians, or some more highly constituted authority, and which require vaccination to be performed from the arm of a healthy child, are approved of. The memorial is dated May 11th, and is signed by John H. Gibson, M.R.C.S.; William Lunn, F.R.C.S.; Robert Hardy, M.R.C.S.; William Joseph Lunn, M.D.; Henry Munroe, M.R.C.S.; F. R. Horner, M.D., M.R.C.S.E.; Henry Cooper, M.D., F.R.C.S.; Owen Daly, B.A., M.B.; Robert M. Craven, jun., M.R.C.S., L.A.C.; James Dosser, M.R.C.S.E., L.A.C.

THE INCOME TAX. The new bill on the income tax is now published. The new law is to date from the 5th of April last; and, according to its phraseology, is to continue to the 6th of April, 1860, "and no longer". The duties to be imposed are as follows: During the term of two years, from the 5th of April, 1853, the yearly duty of 7d. in the pound; and during the further term of two years, from the 5th of April, 1855, the yearly sum of 6d.; and during the further term of three years, from the 5th of April, 1857, the yearly sum of 5d. On lands and tenements, etc., for the first two years, in England, the duty is to be 3½d. in the pound, and in Scotland and Ireland 2½d.; for the second two years, 3d. in the pound in England, and 2½d. in Scotland and Ireland; and, for the last three years, 2½d. on property in England, and 1½d. on property in Scotland and Ireland. Houses let in several tenements are to be charged on the landlord. To exempt persons from the operation of the measure, their incomes must be under £100; and, if under £150, they are entitled to an abatement. Persons who have made insurance, or contracted for a deferred annuity on the lives of themselves or wives, are to be allowed an abatement of duty in respect of the annual premiums.

UNIVERSITY OF LONDON. Petitions in favour of extending the Parliamentary franchise to the University of London have been presented to the House of Commons from the following places and persons since the 10th instant:—Great Yarmouth, Hastings, Dublin, Westminster, Stepney, Bradford, Stockport, Norwich, Brecon, Wandsworth, Canterbury, Royal Free Hospital, Brenchley, Huddersfield College, Leeds School of Medicine, and from the inhabitants of Bucks. The total number of petitions presented now amount to 90.

THE SURGEONS AND THE GUARDIANS OF THE POOR OF THE BISHOP STORTFORD UNION.

THE Surgeons of the Bishop Stortford Union have formed themselves into a Society, and have lately passed a resolution to resist a reduction in their salaries without good reason being shewn to justify the reduction. They have refused offers to continue their appointments, because the offers were upon a scale of reduction unexplained, and because the treatment they have received at the hands of the guardians was wanting in proper courtesy to them as professional men.

The surgeons have explained their conduct in a sensible and temperate address, which we subjoin for the benefit of those who may be similarly placed.

THE POOR LAW AND ITS MEDICAL OFFICERS.

While changes are being made from year to year by the powers which move the machinery of the POOR LAW, it may not be out of place to enquire into the position of the MEDICAL OFFICERS; how they are regarded by those who immediately appoint them; what evil keeps alive mistrust between both officers and guardians; and why the profession loses caste by the present contract system?

Is the profession, to serve the purposes of the poor law, supposed to be needy? Is it supposed to be ready to undertake, at the instance of its employers, any district, however much to its own inconvenience? Is it supposed to hold a jealous fear of its fellow-labourers? Can it offer a manly resistance against such oppression as weak minds and false economy alone suggest, and not fear lest a successor be appointed in its place? Is it supposed to be the creature of a year's appointment? that its reappointment may carry with it any changes, however off-hand, frivolous, or vain those changes may be, either in stipend or district? Is it supposed to bow to some local interest which keeps it in its place? If so, well may it be felt to move in degradation.

Does not the poor law believe that the above is the condition necessary to be found and treated with? and if not, why has the profession had so many reasons for thinking so?

The medical profession has long entertained a great grief against the poor law agents, and has long endured a *sic volo, sic jubeo* treatment, oppression without redress; but instances have lately proved that a better spirit is capable of being aroused on its behalf: it believes that the time is come when its cause will be acknowledged beyond the limits of the union house, and that the public will sympathize with it in all its wrongs, and raise its voice to assist in securing for it its rightful claims; or, as can be seen in many unions, respectable members will fall away from the undertaking, and the care of the poor be literally sold to adventurers.

It will be necessary to view the district, the stipend, and the contract, as the three principal features of this appeal; it is hoped, that each, in the bearing it takes, will help to prove that the profession only claims a higher standing than is usually awarded to it by poor law dealings; and that its own strength, while the public is with it, is all that is required to place it firmly in its true position.

The district should be considered a widely-spread infirmary or hospital; the approaches to the wards being neither ready nor convenient, and hospital nicety adding nothing to accommodate the intended cures; but however rude or inconvenient its character, let it be considered a widely-spread hospital, the medical care of which, as in all hospitals, should be entrusted to those who, with reputation and experience can fulfil all its requirements; but in no case should the claims of him who has faithfully discharged the duties, and whose pleasure it may be to continue those duties, be supplanted upon *little misunderstandings*, or from the wrong desire to make insignificant and worthless changes.

In the stipend agreed upon, be it what it may, the poor law insists that the profession is called upon, by reason of its private interests, to yield its time, its advice, and appliances to the poor law cause as to the mainspring of its own existence. That the profession is called upon to do much for the poor, no member disputes, but surely they who concede so largely to a necessity, should have, not only a voice in the limits of that concession, but should always, in matters in any way affecting their duties, be *considerately and delicately*, not to say *honestly* consulted, or allowed to form part of the council upon any business in which their services are involved: this would add nothing to the

expense, and might entirely remove mistrust on both sides; for the profession has as keen a sense of right and wrong as other men have; is willing to make any concession at need, and under explanation, which might be demanded at its hands. The poor law at present prefers to treat the profession as if it had always something to propose and carry out, the reason for which would not bear publicity, implying an overreach in the bargain, and so establishing the very mistrust it ought to be but too anxious to dissolve.

The necessity spoken of is that the poor law cannot afford to pay the ordinary *professional remuneration*; the concession is that which the profession makes to the poor law in its difficulty; it undertakes to sacrifice eight out of ten parts of its *usual remuneration*. It is everywhere admitted that the remuneration of private practice is always *hardly earned*, and usage has established the present day remuneration as the *standard value* of its time, its advice, and its cares. The difference between the poor law stipend and this standard, is the difference between £2 and £10, or between £20 and £100; and does not this concession claim for the profession *higher considerations*? Ought it not to have a voice in that council which has charity for its object? Should the poor law keep back one single thought in treating with those who serve the public and the poor to this extent? Or should it, under the cloak of a *public purse*, try by cunning to outwit an unsuspecting confidence? The effect of this is to build up an antagonizing power, and not to secure attachment and strength in carrying out a public duty.

The medical relief of a union is *about* one-twentieth of the gross expenditure; but as government pays one-half of that, one-fortieth is the real cost of such service and advice as the profession supplies to the poor. Upon what pretext must a reduction in such an item stand, when those who pay, or those who appoint, rationally and seriously open their minds to the subject? For, by a reduction of £7, £10, or even £15 per cent. upon the present medical outlay, the largest rate-payer could not be relieved by more than the fraction of a penny at the year's end; and when, as is often the case, such change is offensively proposed, who but the servile would acquiesce?

It seems but too true that the contract, without other consideration, lowers the character of the profession, which becomes a *servant* by a monied contract, and that of a debasing kind; it loses its dignity by showing (however nobly) how little it can work for; its charity, its good heart, its endurance, are never thought of, never uttered, are imputed to base motives; and if instanced under oppressive changes, are replied to by the *monied conditions*. The contract builds up mistrust in the minds of the guardians, because they know that without probity and honour the terms cannot be fairly complied with; they doubt the due fulfilment of the contract, and they hold in contempt while they doubt; and offence is done to the mind of the profession, because without other considerations being named and made to take a prominent feature in the contract, it enters into a bare commercial bargain. The profession does not ask for the *ordinary remuneration*; it does not seek to be estimated by obtaining £5 more for its supply of advice and remedies to 100 sick poor: it is content with what custom has awarded for some years past, but it does firmly and manfully demand to be placed in its proper position; it claims that the contract shall be considered an *honorary contract*,—the stipend being only analogous to the *customary fine* in a lease, its periodical and legal acknowledgment.

This, and the right to be present whenever medical subjects are discussed, are its due; to say nothing of the good that would result to the poor law cause by the harmonizing effect that would necessarily accompany such an understanding. Let the profession only be treated with upon this ground, and with what different feelings might the work be done, and how differently might it be respected? It would prosecute its labours without mistrust from those who appoint, and without offence to itself: for an honourable admission is beyond value in money.

Let the poor law on its part concede in *spirit* what it may not concede in *money*; let it cease to value the *mental and corporeal sacrifices* of the profession in the same list with the *marketable produce* of the soil; let it take to its council those who are most capable of assisting in its deliberations, and it will find its own working power improved, and will see how oppression may be removed from a class whose life is made up of hardships under trials, revolting in most instances to patience and common sense, and whose complaint is against the purely commercial spirit of the treaty as it now exists.

KING'S COLLEGE HOSPITAL. The anniversary festival of this institution was held on Wednesday evening, the 4th instant, at the Albion Tavern, Aldersgate-street, when about 150 gentlemen sat down to an excellent dinner. His Royal Highness the Duke of Cambridge presided, and amongst those present we noticed Admiral Lord Radstock, Lord William Paulet, the Bishop of Chichester, Sir Benjamin Brodie, the Rev. Dr. Jelf, Colonel Fergusson, Mr. William Fergusson, Sergeant Storks, Dr. Budd, Dr. Arthur Farre, Dr. Johnson, Dr. Tanner, Dr. Guy, Mr. Bowman, Mr. Henry Lee, and others. The noble chairman in proposing the toast of the evening—"Prosperity to King's College Hospital," remarked, "that since the establishment of this hospital in 1839, it had afforded relief to 230,941 patients, of whom 16,000 had been treated within the wards, and 215,000 as out-patients. The object therefore for which the institution was established had entirely succeeded; but unfortunately its future operations could not be satisfactorily carried out without receiving liberal support from its patrons. He was sorry to inform them that it was considerably in debt; and that it would be impossible to carry it on effectively unless its friends came forward in a spirit of increased liberality. He had been over the hospital only that morning, and although the building itself was quite unsuited for its present purpose—having been originally a poor-house—still, notwithstanding this disadvantage, the general arrangements were admirable; and he doubted not that when the new hospital now building was finished, it would form one of the most complete establishments of its kind. He had learnt that in 1852 the expenditure was £4,944, and for that sum 1,250 in-patients and 25,000 out-patients had been received, and 500 attended at their own homes; unfortunately, however, there was an excess of expenditure over the receipts of £1,979. He thought it better not to gloss over any difficulty, but to look it manfully in the face; and he trusted that the subscriptions of the present company would show that they were determined to give the institution their cordial support and encouragement." Donations and annual subscriptions were then announced to the amount of £2,111:13:11, including twenty guineas from the chairman. Several other toasts having been proposed and responded to, the company separated.

ST. MARY'S HOSPITAL. The annual meeting of subscribers was held on the 17th instant, in the Board-room, the President, Earl Manvers, in the chair. From the report it appeared that the accommodation had been increased from 50 to 150 beds, and these were insufficient for the demand. Although the progress of the institution was satisfactory, yet a sum of £7,000 was required to complete various important designs, such as a medical school on the collegiate plan, a chapel, and a dead-house. It is also the intention of the Governors to procure a charter of incorporation. The total number of cases treated during 1852 had been 6,541. The receipts for the year were £7,814:14:7, and the disbursements £7,979:14. The report was adopted, and after a vote of thanks to the chairman the meeting separated. We have received a copy of the report, which we may afterwards notice at more length.

ROYAL FREE HOSPITAL. The annual festival of this institution was celebrated at the London Tavern, Viscount Maidstone presiding. The chairman, in proposing "Success to the Royal Free Hospital" stated, that since the opening of the charity, 403,533 patients were relieved. The hospital was in debt to upwards of £1,000, and as the principle upon which it was founded was that of affording medical and surgical relief without the delay of making inquiry as to the applicants, he knew of no charity which was more in accordance with the example of the Founder of Christianity, and none which had more claims upon public benevolence. The donations announced during the evening amounted to £1,360.

WESTERN DISPENSARY FOR DISEASES OF THE SKIN, (21A, Charlotte Street, Fitzroy Square.) A meeting of the subscribers and friends of this charity was held, on Tuesday, 24th May, at the rooms of the dispensary, the Rev. Canon Dale, the President of the institution, in the chair. The report stated that during the eighteen months' existence of the Dispensary, a large amount of good had been effected: that, although chronic cutaneous diseases are often found incurable, yet, out of 442 patients admitted, 192 had already been discharged cured, 44 benefited, and "the remainder, with very few exceptions, advancing as rapidly towards recovery as is possible under the chronic character and protracted duration of the disease". Not one case had been discharged as incurable. The medical gentlemen present spoke in strong terms of satisfaction at this grati-

fying result, and complimented Mr. Hunt, the surgeon to the institution, for his perseverance and success in the treatment of these refractory and tormenting diseases. The report stated that the finances were very low, and that the assistance of the charitable much needed.

ROYAL DISPENSARY FOR DISEASES OF THE EAR, DEAN-STREET, SOHO-SQUARE. The thirty-sixth anniversary meeting of the above institution was held at the Dispensary on Wednesday, the 11th instant, the Rev. J. D. Lamb in the chair, supported by the Rev. W. Brock, Dr. Tilt, J. F. Clarke, Esq., F. Falkner, Esq., and others. During the past year, 1,388 patients were admitted on the books, afflicted with various diseases in the ear, head, and throat, with numerous cases of deafness arising from rheumatism, gout, influenza, and other faulty conditions of the system at large. Of these 559 were discharged cured, 308 discharged relieved, and 521 remain in weekly attendance. The following statement was made by Mr. Harvey, the surgeon to the institution:—"In a large proportion of the cases, the disease may be traced to living in confined and damp localities, to bad drainage, intemperance, want of cleanliness and exercise in the open air, insufficient or adulterated food, wet feet and clothes, and sleeping in damp rooms; incapacitating many from holding situations or following their ordinary employment, and compelling them in too many instances to become the inmates of workhouses."

MEDICAL BENEVOLENT COLLEGE. The first festival of this institution was held on Wednesday, the 4th inst., at the Freemasons' Tavern. The chair was taken by Earl Manvers, President of the Institution: there were also present, the Bishop of St. David's, Mr. Freshfield, M.P., Mr. Pownall, Colonel Hammer, Sir C. M. Clarke, Dr. Conolly, Dr. J. A. Wilson, Dr. Locock, Dr. Forbes, Mr. South, and a large number of practitioners from the metropolis and the provinces. The total number was about two hundred and fifty.

In responding to a toast, the Bishop of St. David's said, it was a source of much happiness to find the medical profession had supported their character as society expected. It had strong claims on the public at large, and upon the whole nation, for the support of an institution like this. No one could deny the usefulness as well as the honour of the profession. It was a very laborious profession, and required much study and care before parties were allowed to practise. A medical man had to pass many sleepless nights, never knowing any regular repose, but always at the call of any person. He exercised his art and gained his triumphs in the chamber of the sick, and so equally alike to rich and poor, that he believed they must have some higher and more noble motive than mere worldly profit. He trusted that this institution would be an object which the public of all classes would join in supporting.

Earl MANVERS proposed "Success and prosperity to the Medical Benevolent College, and to John Probert, Esq., the founder".

Mr. PROBERT said, that a grand principle or rallying point of union in the profession was to prevent their poor brothers going to distress. In his own parish, a brother practitioner was an inmate of the workhouse. They wished to have a union of their own, but not a union workhouse. He was proud and thankful to see the noble-hearted members of the profession come forward as they had done. They could not go on without the "sinews of war", and he had much pleasure in reading a list of subscriptions, which exceeded £7,000, including from the Surrey Medical Society the sum of £2,000 for the endowment fund, and £500 to the building fund.

Mr. Probert proposed "The Honorary Local Secretaries". The exertions were most satisfactory. In the last three days even, they had opened fresh ground, and had contrived to extend the society throughout the length and breadth of the land.

This toast was responded to by Mr. CARDEN, of Worcester. The Chairman retired about eleven o'clock, when Sir C. M. Clarke was called to the chair, and the festivities were prolonged to a late hour.

SERMON IN AID OF THE MEDICAL BENEVOLENT COLLEGE. The sum of £130 was collected in the Church of St. Peter's, 100 Street, on Sunday, May 8, after a Sermon preached by the Bishop of Oxford. His lordship contributed £30.

THE CRIMINAL ABORTION CASE. Mr. Charles O'Connell, alias Smith, alias Taylor, and Mr. James Thomas, alias George, (?) and Mr. George Thomas, chemist, who have been in custody for some time on a charge of procuring abortions, were

use of instruments on the person of Miss Eliza Morden, were, on Saturday last, again placed at the bar of the Lambeth Police Court for further examination.

Superintendent Lund asked for a further remand, on the ground that the principal person accused—the Rev. Mr. Gordon—was not yet in custody, and for the production of other evidence. He stated that he knew where Mr. Gordon was, but whether he should be able to take him he was not prepared to say.

Mr. Binns, on behalf of the prisoners, did not object to a remand, particularly as the case would eventually be submitted to a jury; but he hoped that on the next occasion Mr. Lund would be in a position finally to close the evidence, in order that there might be time for preparing the defence.

Mr. Lund said he hoped he should be able to do so.

The prisoners were then remanded.

It appears that the penalties to which the accused are liable are very severe, for the 6th section of the act holds the crime to be a felony, and those convicted to be liable, at the discretion of the Court, to be transported for life, or for any term not less than fifteen years, or to be imprisoned for any term not exceeding three years.

CHARGE OF RAPE AGAINST MR. SHORTHOUSE, A UNION SURGEON: ACQUITTAL. At the Croydon Sessions, a young girl named Duff, residing with her parents at Carshalton, charged Mr. Shorthouse, one of the surgeons to the Croydon Union, with rape, committed in his surgery while she sought his professional advice. The prosecutrix swore that Mr. Shorthouse applied some lint to her face, when she immediately became insensible; and that during her unconsciousness he committed the felony, which in five months afterwards he repeated. The father was examined as a corroborative witness. Mr. Doubleday, surgeon, the Rev. Mr. Eaton, and Mr. Shorthouse, so satisfactorily disproved the charge, that the magistrates, without retiring, immediately dismissed the summons; stating that Mr. Shorthouse left the court without the slightest stain upon his character. Anne Duff was held to bail to answer the charge of perjury. She has recently been tried, and acquitted.

THE SPECULUM: CRIMINAL CHARGE AGAINST A PHYSICIAN. Dr. Banks, a physician of considerable standing and extensive practice, residing at Louth, in Lincolnshire, and a magistrate for the borough, has been committed for trial at the next Spilsbury Quarter Sessions, for an assault with intent to commit a rape on Emma Lockwood, a girl of 16 years age, the daughter of a respectable tradesman at Tetford, near Horn-castle. It appeared from the depositions, "that John Tatam Banks did, on Wednesday, the 20th April 1853, at his consulting room, in Eastgate, assault Emma Lockwood, with intent, etc.; that the prosecutrix had been his patient for a year past, for an imaginary disease of the womb; that her mother had come with her, and had been sent by the doctor into the town, and during her absence he, under pretence of a medical examination, behaved improperly, and made an attempt, etc., but met with resistance." The magistrates, after some discussion on a point raised by Dr. Banks's counsel, Mr. Adams, as to whether the offence was merely a common assault, finally decided on committing the doctor to take his trial for the graver offence, and admitted him to bail, himself in £500, and two sureties in £250 each.

[The accused is innocent, we sincerely trust; but the occurrence of such charges points out the care which ought to be taken, not to allow even a suspicion of improper conduct to arise, or the possibility of such an accusation having even a semblance of truth. The presence of a third party is a prudent precaution; and the unnecessary use of the speculum ought to be more guarded against than it is at present. EDITOR.]

TESTIMONIAL TO W. J. T. MORTON, Esq. The students of the Royal Veterinary College, London, presented, on the 16th ult., to their lecturer on Chemistry, a magnificent flower-vase mounted in ormolu, with a pair of candelabra to match; also a pair of richly ornamented silver covers. On the vase was the following inscription:—"Presented, with other articles of vertu, by the students of the Royal Veterinary College, to W. J. T. Morton, Esq., professor of Medical Chemistry and Materia Medica in that Institution. A tribute of esteem and gratitude, equally in acknowledgment of his assiduousness as a teacher and his kindness as a friend. Session 1852-3."

THE STAMP DUTY ON DIPLOMAS. The following letter has been received by Dr. Hawkins, the registrar of the Royal College of Physicians, from the Secretary of the Chancellor of the Exchequer:—

"Downing Street, May 5, 1853.

"SIR,—The extreme pressure of public business which has lately engrossed the attention and entire time of all those connected with this department, has occasioned the delay which has occurred in the acknowledgment of the representation, which, on behalf of the Royal College of Physicians, you submitted to the notice of the Chancellor of the Exchequer.

"I am directed by him to assure you, that he will not fail to investigate and give his careful attention to the subject of the Stamp Duties now imposed upon the licenses and diplomas of the College of Physicians.

"I am, etc.,

"FRANCIS LAWLEY."

THE MEDICAL PROFESSION AT THE ROYAL ACADEMY EXHIBITION. Among the portraits and busts of the present year, there are some eighteen or twenty of medical practitioners. We may point out two pieces of sculpture well worthy of inspection. The first, numbered 1400, and described in the catalogue as a "Marble Bust of James Moncrieff Arnott, Esq., F.R.S., late President of the Royal College of Surgeons; executed by (H. Weeks, A.) order of the Council," is an admirable likeness, and a fine specimen of the sculptor's talent. The second, numbered 1450, is a bust in marble of the late J. Dalrymple, Esq., F.R.S., and is about to be presented by some of this gentlemen's medical friends to the College of Surgeons. The likeness is good and pleasing. This testimonial was first proposed, we believe, by Dr. Bence Jones.

COMMON LODGING-HOUSES. Lord Shaftesbury has laid on the table of the House of Lords a bill, which has been just printed, for making further provisions with respect to common lodging-houses. Among the alterations, it is proposed that a conviction for a third offence shall disqualify a person from keeping a common lodging-house. Power is to be given to inspect common lodging-houses. All such places are to be registered before they are used. A certificate as to character may be required for common lodging-house keepers. Sick persons may be removed from common lodging-houses; and compensation for loss of bedding, etc., is not to be paid to offenders against the act. The term "common lodging-house" is to extend to other houses than at present.

LUNATICS. The House of Lords has printed a return of the number of lunatics under inquisition who are resident in asylums, and the amounts of their respective incomes and allowance for maintenance. There are 238 persons confined in asylums, including licensed houses. In many of the cases, the whole income is applied for maintenance. The largest income in one case is £5,000 a-year, of which £700 is for the support of the lunatic, and £2,500 for keeping up Hazelwood Castle.

THE LUNACY BILLS IN THE HOUSE OF COMMONS. On the motion of Mr. Walpole, the three bills on this subject which have lately been passed by the House of Lords, were read a first time on the 12th of May.

YELLOW FEVER AT RIO DE JANEIRO. By the *Severn*, which arrived at Southampton on the 17th, it was reported to Mr. Wiblin, the medical superintendent of Quarantine, that this disease continues on the increase, both amongst the shipping in harbour, and on shore. During the month of March, one hundred and forty-five cases had occurred at Rio, and about fifty cases weekly amongst the shipping in that harbour. At Bahia the disease had broken out, and forty-five cases had occurred during the same month. The *Severn* had six cases of yellow fever on her homeward voyage. Fifteen days having elapsed since the last new case, pratique was given to her, after answering in great detail the new quarantine questions. The R.M.S.Co.'s ship *Oromoco*, arrived at Southampton on the 18th, having had fourteen cases of yellow fever, and two deaths. In consequence of one man being an invalid, and as yellow as a guinea, Mr. Wiblin had the vessel detained for four hours. There were several invalids, but he thought it prudent to order one man to be detained at the company's Buoy, in charge of a company's officer, for a day or two, with the yellow flag hoisted. Yellow fever is again very bad at St. Thomas's, nearly all the above cases having occurred before departure.

UNIVERSITY OF ST. ANDREW'S. List of gentlemen who had the degree of Doctor of Medicine conferred upon them May 6th, 1853:—William Field Bellin, M.R.C.S., L.A.C., Great Yarmouth; Frederick James Chaldecott, M.R.C.S., Dorking, Surrey; Henry James Collett, M.R.C.S., L.A.C., Worthing, Sussex; Clarence Cooper, M.R.C.S., L.A.C., Brentford, Middlesex; Frederick Charles Cory, M.R.C.S., L.A.C., London; James Davidson, M.R.C.S. Ed., R.N.; José Maria De Mier, M.R.C.S., London; Thomas George Dixon, M.R.C.S., L.A.C., Northwich, Cheshire; Joseph Ewart, M.R.C.S., Guy's Hospital, London; John Gallagher, M.R.C.S., R.N.; Henry Joseph H. Griesbach, M.R.C.S., L.A.C., King's College, London; Richard Savill Hanbury, M.R.C.S., L.A.C., Mirfield, Yorkshire; William Harrison, M.R.C.S., L.A.C., Yorkshire; Richard Cleve Heighway, Lic. Fac. Phys. and Surg. Glasgow, Shrewsbury; John Hilliard, F.R.C.S., L.A.C., H.E.I.Co.'s Service, Bengal; Thomas James Holmes, M.R.C.P., M.R.C.S.; L.A.C., Lyme Regis, Dorsetshire; Edward Jones, M.R.C.S., L.A.C., B.A. Paris, Dover, Kent; John Livy, M.R.C.S., L.A.C., Bolton-le-Moors; Draper Mackinder, M.R.C.S., L.A.C., Gainsborough; Henry Montford, M.R.C.S., L.A.C., Douglas, Isle of Man; James Nicholas, M.R.C.S., L.A.C., St. Columb, Cornwall; Andrew Graves Power, M.R.C.S., L.A.C., London; William Henry Rean, M.R.C.S., H.E.I.Co.'s Service, Madras; Alexander C. Ross, M.R.C.S., M.B., Inverness; Hugh James Sanderson, M.R.C.S., L.A.C., London; Benjamin Simpson, M.R.C.S., B.A., Trin. Coll. Dublin, H.E.I.Co.'s Service, Dublin; John Tibbits, M.R.C.S., Warwick; George Lawson Thomson, M.R.C.S. Ed., Coldstream; Henry Turner, M.R.C.S., Clonakilty, Co. Cork; Joseph Haydon Ward, L.A.C., Epsom, Surrey; Heaton Lloyd Williams, M.R.C.S., Denbigh, North Wales; Andrew Wynter, London.

UNIVERSITY OF GLASGOW. At the April Graduation of this University the degree of M.D. was conferred on the following gentlemen, who were examined in the various branches of medicine and found duly qualified:—Henry Hancox, England; George H. B. McLeod, Scotland; Richard Stanistreet, Ireland; John H. West, Ireland; Robert Harmer, England; Connell F. Loughnan, Ireland; James W. Frame, Scotland; Robert Paterson, Scotland; John E. Corbett, Scotland; John McCulloch, Scotland; James Dick, Scotland; Gilbert Adams, United States of America; Bruce Goff, England; Robert A. Allen, Ireland; John R. Brown, Scotland; Charles D. Campbell, Ireland; Daniel Dewar, Scotland; David Pollock, Ireland; William Stevenson, Scotland; Walter S. D. Yates, India.

ROYAL COLLEGE OF SURGEONS.—PASS LISTS. MEMBERS admitted at the meeting of the Court of Examiners on the 29th ult.:—Humphry J. Gillett Atkinson, Dublin; Edwin Stephens Collins, Sherborne, Dorset; W. Harrison, Gargrave, Yorkshire; Marcus George Hill, Chelsea; Frederick Abell Humphry, Balham-hill; John Jones, Ruthin, Denbighshire; William Kaye, Knaresborough, Yorkshire; John Robert Low, London-fields, Hackney; Henry Frederick Marley, Port Isaac, Cornwall; Herbert Eady Proctor, Brackley, Northamptonshire.

On the 6th inst.:—Henry Toussaint, Ceylon; George Alder Watson, Scarborough, Yorkshire; Jesse Conway Davies, Holywell, Flintshire; Charles Hemming, Kimbolton, Huntingdonshire; Philip Warren Sutherland, Hon. East India Company's Service; David Mathias, Cardigan; James Ray, Lowestoft, Suffolk; Peter Williams Rolston, Devonport; Arthur Anthony Harris, Warrington, Oxfordshire; Edward Snell Wallis, Dublin; Lloyd Herbert, St. Mary Bourne, Hants.

FELLOWS admitted at the meeting of the Council on the 12th inst.:—James Penn Harris, Clarence Street, Liverpool, diploma of membership dated May 3rd, 1841; Samuel Belton Gwynn, Wem, Salop, Aug. 2nd, 1844; Richard Barwell, Maddox Street, Oct. 6th, 1848; Thomas Bryant, Montague Place, Clapham Road, Aug. 6th, 1849; Timothy Holmes, Hamilton Terrace, St. John's Wood, not a member.

LICENTIATES IN MIDWIFERY admitted at a meeting of the Board of Examiners in Midwifery, on the 11th inst.:—W. Field Bellin, Great Yarmouth, diploma of membership dated July 12th, 1852; George Fowler Bodington, Sutton Coldfield, Nov. 9th, 1849; John Matthew Butler, Woolwich, Dec. 10th, 1852; Thomas Henry Cheate, Burford, Oxon, Oct. 15th, 1852; Geo. Connor Cornelius, St. George's Villas, Canonbury, July 28th, 1853; Thomas Frederick Hale, Petworth, April 1st, 1853; Lloyd Herbert, St. Mary Bourne, Hants, May 6th, 1853; David Mathias, Cardigan, May 6th, 1853; John Benson Pritchett, York, March 23rd, 1853; Henry Joseph Stormont, Wallingford, July 23rd, 1850; William Walker, Hermitage Place, St. John Street Road, July 15th, 1856.

APOTHECARIES' HALL.—PASS LIST. Thursday, April 28, 1853:—George Stewardson Brady, Gateshead; Frances Russell Hall, Fulhouse, Cambridgeshire; James Ireland, Provost-street, Hoxton; John Phillipson Langham, Forest of Dean; Edwin Moore; Richard Burford Searle, Bridport, Dorset; John Smith, Wheatley, Oxon; Eustace Carey Summers, Rothbury, Northumberland; Edward Swales, Helmsley, Yorkshire.

Thursday, May 5th, 1853:—Thomas Brookes, Whitchurch, Salop; Edward Clapton, Stamford Lincolnshire; Thomas Fred. Hale, Petworth, Sussex; Joseph Porter, Rotherhithe Street.

Thursday, May 12th, 1853:—John Charles Barrow, Loughborough; Wm. Thomas Bell, Great Grimsby; George Fowler Bodington, Sutton Coldfield; William Lucy, Bristol; Broome Pinniger, Westbury, Wilts; Robert Bath Smart, Balsham, Cambridgeshire.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

BEALE, Lionel J., M.B., elected Joint Professor of Physiology with Mr. Bowman at King's College.

HASSALL, Arthur Hill, Esq., elected Physician to the Metropolitan Free Hospital.

HEADLAND, F. W., Esq., B.A., appointed Lecturer on Botany at the Charing Cross Hospital.

RADCLIFFE, Charles B., M.D., elected Assistant-Physician to the Westminster Hospital.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

BIRCH, Wm. Richard, Esq., aged 20, a student of St. Bartholomew's Hospital, at the residence of his brother-in-law, Frederick Wood, Esq., apothecary to the hospital, on May 15th. He died of typhus fever, accompanied with the usual maculated rash, after only a few days' illness. This gentleman was much esteemed by his fellow-students for his talents and kindness of disposition. Another of the students is severely ill of the same disease. Both gentlemen were holding the appointment of clinical clerk.

DAWSON, Edwin, Esq., Surgeon, at Wainfleet, Lincolnshire, of carcinoma of the stomach, aged 67, on May 18.

RICHARDSON, Robert, Esq., Surgeon, late of Harrogate, Yorkshire, at Ross House, Cheltenham, on May 20th, aged 80.

STEVENS, Alexander C., Esq., late of Falmouth, Jamaica, at Duncan Street, Edinburgh, on May 19.

WALKER, David, M.D., younger son of Mr. W. Walker, schoolmaster, Earlstoun, N.B., at the residence of his brother, Tyndale Place, Islington, on May 1.

WESTALL, William, Esq., Assistant Surgeon of H.M. 94th Regiment, on board the *Zemindar*, while returning from Australia to rejoin his regiment at Madras, aged 30.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXII.

LONDON: FRIDAY EVENING, JUNE 3, 1853.

NEW SERIES.

GENTLEMEN WISHING TO JOIN THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION ARE REQUESTED TO APPLY TO THE GENERAL SECRETARY, TO THE BRANCH SECRETARIES, OR TO THE EDITOR OF THE JOURNAL.

The Annual Meeting will be held at Swansea on the 10th and 11th of August. Vide p. 470 of last number.

PROGRESS OF MEDICAL REFORM.

We content ourselves to-day by reporting the progress of events, and congratulating the profession on the spirit of zeal and conciliation which is every day abounding more and more in our ranks.

To-day, at 3 P.M., about the hour at which our paper will reach our readers in London and the adjacent towns, Lord Palmerston will be engaged with a deputation from Dr. Lankester's committee, whose mission it is to press upon his lordship the urgency of the evils under which the profession of medicine now groans, and the favourable opportunity which now exists for removing at least some of them. As a definite YES or NO must be given by the minister to the question, whether government is willing to introduce a Medical Reform Bill during the present session of Parliament, we shall be able in our next to announce either the certainty of a speedy termination being put to much of the anarchy which now prevails in the medical profession, or to indicate the outlines of a new and more aggressive campaign against monopoly and oppression, than any which the great body of the profession has yet found itself sufficiently united to undertake with the confidence of victory.

As regards what is going on within the pale of our ASSOCIATION, we may state generally, that much is in preparation, and that several active auxiliary committees have been formed. The Medical Reform Committee of the Metropolitan Counties Branch met on Friday last. The proceedings of the Committee will be found at p. 492.

So far as we can learn, the statistics of petitioning up to this date are as follows:—

Places formerly mentioned . . .	18
London	6
Banffshire	1
Yorkshire Branch	1
Wisbeach	1
Bath	1
	—
Number of Petitions	28
	—

Many other places have petitions in course of signature. We have only mentioned those petitions which have been

actually presented, or placed in the hands of members of Parliament for presentation.

Another indication of the progress which the medical reform question is making, is the attention which it is exciting among influential writers on general politics. We formerly alluded to the aid which the cause was receiving from the *Daily News*; and we may now mention two other metropolitan papers unconnected with medicine, which have not only written with power and clearness upon the present aspect of our professional affairs, but have expressed a feeling decidedly favourable to the present movement.

The *Legal Examiner* of May 28th, says—

"The medical profession, who have made so many abortive attempts to get the anomalies of their present condition removed by legislative enactment, are just now engaged in another effort for this purpose. The Provincial Medical Association, who have, since their first organization more than twenty years ago, gradually grown into the most powerful of all the professional bodies, some time since presented a bill to Lord Palmerston which represented their opinions, and aimed to carry out the views they always advocated. They, however, pointedly stated, that they had no object except to obtain a measure that should be acceptable to the whole profession, and that they should therefore support any bill that the Government might frame, provided only it was based on the same *principles* as their own."

The *Morning Post* of May 20th, remarks:—

"As medical laws at present stand, a gentleman, even though he may have obtained the highest university medical honours, *has no right to practise in London*. He must also obtain a license from the College of Physicians, and this license, strangely enough, does not qualify him to practise out of London; nor has the extra-metropolitan license a fuller reciprocity. Meantime, amidst all these conflicting privileges and powers, the empiric plies his vocation with impunity and *éclat*. If he self-impose the title of 'Doctor', the law is powerless to check him; or, if too conscientious for this, he long for the real prefix, this boon he can obtain, such as it is, from many a German university for the trifling consideration of a few pounds sterling. There ought to be an end to these disgraceful transactions. Seeing that the medical profession is well-nigh unanimous, and the legislature disposed to act, we trust to witness an efficient medical reform.

"Having touched upon this subject, it is no more than an act of simple justice to direct public attention to the magnanimous liberality of sentiment which has actuated the London College of Physicians. This ancient and learned incorporation, although invested by law with numerous and stringent powers—although possessing highly remunerative vested rights in relation to their medical brethren—has, *proprio motu*, ranged itself in the foremost rank of medical liberals."

THE QUEEN AND CHLOROFORM.

WE should not have again alluded to this subject, unless to protest against the very unsound principle in medical practice, that there is one treatment for the higher, and another for the lower classes, and that a queen is not to be treated medically like the poorest of her subjects. If the risk of giving chloroform in midwifery is too great for the Queen, it is too great for her meanest subject. Disease is no respecter of persons, nor ought the healers of disease to respect persons. Buonaparte, with his intuitive sagacity, said this when he told the accoucheur to treat the Empress as he would a market-woman. He well knew that this was the only safe course in extremities. The opposite course, however, is a very common one. No one who inspects himself as well as others, can have failed to feel that respect of persons is a constant source of bad practice, and that the most successful are those who can calmly and fearlessly treat the highest and most important life as they would the humblest. There are often good reasons, owing to greater delicacy of organization, for prescribing differently for the high and the low, but this is not the question at issue. The rank and standing must be forgotten, and the human being alone remembered. Indeed, it is one of the penalties which the highest pay for their greatness, that they may not be treated with the same promptness and fearless decision as those whose lives seem less important. "If I could only prescribe for my wealthy patients with the freedom I do for the poor, I should be much more successful," said a good practitioner who knew his infirmity. We can imagine that in this recent instance the royal patient would have scorned that fear which would deprive her of the advantages which her subjects enjoyed, and would admit no excuse founded on her high position; courage and honesty are known to be her royal characteristics. The fears, the hesitations, the traitorous doubts engendered by respect of persons in the medical mind, when forced to a prompt decision in the treatment of important persons (and importance here is a relative term, taking in an extensive series of grades), are evidences of a condition of mental weakness so prejudicial to the healing art, and so common, as to justify us in learning a lesson from the historical fact which we formerly announced and commented upon.

THE LAW OF SCOTLAND AND THE MORE FLAGRANT FRAUDS OF MEDICAL QUACKERY.

SOME weeks ago, two quacks appeared in Edinburgh, under the names of "Professors Curtis and Campbell, the celebrated Botanical Physicians". By means of large hand-bills, of the most varied and imposing typography, the rogues were enabled to levy a considerable tribute upon the valetudinarian quack-fanciers of Edinburgh and the suburban villages. One of the hand-bills is now before us. It is surmounted by the Royal Arms of the United Kingdom,

and the words *NIL DESPERANDUM* in bold characters. Premising that we do the Professors injustice by quoting their manifesto, bereft of its diversified capitals, long lines, and short lines, we extract a portion of the hand-bill to which we have referred.

"The art of healing had its origin in the woods; and the forest is the best medical school. Professors Curtis and Campbell, the celebrated botanical physicians (from the Royal Botanic College of Health), Kingsland Road, London; Princes Street, Edinburgh; and 124, Shore, Leith; beg leave to inform the inhabitants of this neighbourhood and environs that they have but recently arrived from America, and are at present on a professional tour for the benefit of those afflicted with diseases who cannot undertake the fatigue and expense of applying to the doctors at their own residence; and likewise for the purpose of establishing agents for the sale of the following medicines—all of which may be relied on as purely vegetable, and as having under their directions effected many cures. Deafness, and all diseases of the eye, perfectly cured, provided the sight is not gone, or the drum of the ear broken. Ruptures permanently cured without a truss, provided the patient is not too old. The following complaints effectually cured."

[Then follows a list of thirty-five diseases, very similar to the lists usually adopted by advertising empirics.]

In Scotland there exist two excellent guardians of the public, which are very much required in England, viz., a public prosecutor, and a wholesome comprehensive statute, enacting penalties for those who are guilty of "falsehood, fraud, and wilful imposition". Professors Curtis and Campbell did not reckon on the risks they ran when they crossed the border as "botanical physicians". The public prosecutor (the "procurator-fiscal" for Midlothian), as in duty bound, came forward to protect the lieges, and arraigned the swindlers before the sheriff of Edinburgh. It appeared on the trial, that they had represented themselves as able to cure all manner of diseases. They charged five shillings for their boxes and phials. A Musselburgh victim having discovered that the chief ingredients of the mixtures were cod-liver oil, soap, and rhubarb, though represented as composed of other ingredients, informed the authorities. The case was clearly made out; and the sheriff sentenced the quack doctors to "nine months imprisonment, with hard labour".

We hope to see the same course adopted in the north with reference to other medical pretenders, such as the "galvanists", and the "practitioners in synovial disease", who cure all maladies by rubbing. Let us also trust that a protective legal machinery, as effectual and as simple, may ere long be granted to England. This is a point to which we are anxious to direct public and professional attention; and it is for this purpose chiefly that we have prominently set forth an example of the way in which the law of Scotland is made to bear upon the more flagrant frauds of medical quackery. The want of a public prosecutor is a glaring defect in the criminal jurisprudence of England, which ought at once to be remedied.

ORIGINAL COMMUNICATIONS.

ON THE ANÆSTHETIC PROPERTIES OF THE LYCOPERDON PROTEUS, OR COMMON PUFF-BALL.

By BENJAMIN W. RICHARDSON.

[Read before the Medical Society of London, on May 28th, 1853.]

A FEW months since, I had a conversation with my friend Mr. Henry Hudson, a Leicestershire surgeon, on the management of bees; and was particularly interested in his description of an old, and, as I now find, very prevalent custom, of stupifying these insects with the smoke of the fungus known under the name of puff-ball, before extracting the contents of the hive. By this stupifying process, the bees, I was told, could be rendered inactive and insensible for several minutes; but that they all recovered eventually in the most perfect manner, and that the cruel practice of destroying them with the fumes of sulphur was thus avoided.

This practice of rendering bees insensible by inhalation is so much like the modern plan of producing narcotism in men and animals by ether and chloroform, that my mind very naturally seized the analogy; and I was induced to perform a series of experiments on animals with the fungus.

My first experiment was made on the 28th of last March. A kitten was placed in a bell-shaped glass vessel, open at bottom and top. Smoke from a piece of the fungus ignited was allowed to rise pretty freely into the bell; but several interruptions occurred, so that thirty-five minutes elapsed before any positive effect took place. By that time, however, the creature was fairly narcotized: a cut in the ear produced no sign of pain. The breathing was reduced to eight respirations per minute, and the temperature of the body was lowered. From time to time, after removal from the bell, I counted the breathing and the heart-beat, and found them gradually increasing in number, and the body becoming warmer. The sleep, however, was profound; and, after a period of two hours, no sign of sensibility to pain could be elicited. I laid the animal down by the side of her mother, and in the morning found her skipping about as well as ever.

The second experiment was performed on a dog. It was placed in a box, in which it had sufficient room to turn round, and in which the atmospheric air could enter freely from the top. The smoke of the fungus was admitted through the bottom of the box, and the animal was fairly narcotized in a quarter of an hour. On removing it on to a table in the narcotized state, a deep puncture was made in the nose: blood of a bright red colour flowed freely, but no sign of pain was given. The symptoms that preceded the narcotism were those of intoxication; the animal turned round several times; power in the legs ceased; and it fell down at last on its side, insensible; the bowels acting involuntarily. For five minutes after the anæsthesia had come on, the respirations numbered forty-eight per minute; but the heart-sounds were steady, and comparatively slow; the first sound corresponding to each inspiration. The body was warm. Five minutes later, there was a convulsive fit; but the body was still insensible, and the pulse forty per minute. The pupil was dilated and fixed, but the head was drawn back when a light was brought near to the eye. Three minutes later, the animal was becoming conscious, and wagged its tail when spoken to, but showed no pain when pricked with a knife. At a quarter past nine, it commenced to wince when pinched, and crawled about in a reeling manner. From this time, the recovery was rapid; and in ten minutes the creature seemed as well as though nothing had been done to it.

In a third experiment, at which Dr. Crisp was present, a dog was again the subject. There were the same symptoms of intoxication, but complete narcotism set in in six minutes. In this case, the narcotizing agent had been

given more freely and steadily than in the previous cases. Eighteen minutes after removal from the box, the animal remained insensible to pain, but was conscious when spoken to. Blood drawn from the nose was of a bright red colour. The other symptoms were very similar to those described in the last experiment. Two minutes later, rallying commenced; and in twenty minutes the creature had quite recovered. We remarked, that the sensibility returned in the fore legs previous to returning in the hinder ones.

Finding that the impure fumes of the burning fungus were rather painful to breathe, as they produced some degree of irritation in the throat, and caused the eyes to water, I made them pass through a solution of caustic potash, previous to exposing the animal to their influence. This was easily done. The smoke, being produced in a large closed vessel, was forced by water-pressure through a Wolff bottle containing a solution of caustic potash, and was received in an inverted glass bell. I thus obtained a perfectly clear gas, free from carbonic acid. A young cat was now placed under the bell; she became slightly convulsed in thirty seconds, and was profoundly narcotized in two minutes. The heart-beats were not much affected, and recovery took place in seven minutes after removal from the vessel.

This experiment was performed on the 13th of April; and on the following day I repeated the experiments, both with the impure and clarified vapour, in the presence of Dr. Willis and Dr. Cormack, with complete success.

Mr. Sampayo, a gentleman residing in Barnes, had a favourite dog, which was very old, was constantly troubled with cough, and had a large and painful tumour over the abdomen. As the owner of the dog wished to have this tumour removed, Dr. Willis thought there would be a good opportunity for trying the anæsthetic power of the fungus during an operation. He therefore kindly undertook to cut out the growth, if I chose to produce narcotism. I did so with the impure smoke of the fungus. The animal was narcotized in six minutes; and the operation, which occupied ten minutes, was done without the merest sign of pain until the last suture was being put in, when wincing took place. Neither the heart nor the respirations seemed much affected in this instance. The recovery was so rapid, that, in six minutes, it would have been impossible to tell, without previous knowledge of the fact, that the animal had been subjected either to narcotism or operation.

I need not occupy time in giving the details of several more similar experiments; I will, therefore, refer only to a few others, which are of special interest.

On several occasions I have given the narcotizing vapour in limited quantities, and for a long time. This dilution of the narcotic has been effected either by mixing the clarified fumes of the fungus with a large quantity of atmospheric air, or by using a preparation of the fungus, which has been deteriorated by charring it, as I think, and which is sold in the shops under the name of "prepared fungus for fumigating bees". In this diluted shape, the narcotic produces a modified class of symptoms. Narcotism is induced very slowly, the animal reeling for a long time, and seeming to be paralysed, without being altogether free from pain. Convulsions, too, and vomiting, are apt to come on, and the animals recover gradually, but surely. I experimented on three animals, in the presence of Dr. Snow, in which these results followed. One of the animals vomited; and in all the cases, the anæsthesia, though sufficiently marked, was not so perfect as in some other instances. By continuing the exhibition of the narcotic, however, we succeeded in destroying a rabbit. The symptoms which the very diluted fumes of the fungus produce in animals, are somewhat like the effects of tobacco in persons who are not accustomed to smoke, with the addition of more decided narcotism and insensibility. It is worthy of remark, that an animal can be made to tolerate this narcotic by inhaling it frequently. I have a dog on which I have experimented from the first. Originally, the creature would come under the influence of the narcotic in six minutes; she will now inhale it, in liberal proportions, for an hour, at the end of which time she is intoxicated, and vomits if she has had a meal previously;

but she is quite conscious, answers to her name, and tries to walk; the sensibility of the body being absent altogether, and the limbs occasionally convulsed. It requires a space of half-an-hour for her to recover from this condition. I have noticed that young animals, whose respirations are quick, although rapidly narcotized by a large dose of the substance, resist the action of a diluted dose very obstinately. I have kept young kittens for more than an hour in the vapour, and, under its influence, rolling about in the most drunken manner, but not absolutely insensible; when, however, complete narcotism does set in, it continues for a long period.

It occurred to me to give the narcotic in connexion with oxygen gas: the fungus was therefore burned in oxygen, and the dense fumes produced were clarified by caustic potash, and were passed into the glass bell, together with some free oxygen. A young cat was placed under the bell: she became uneasy in thirty seconds, and was fairly narcotized in a minute and a half. On removing her from the glass, the respirations were forty-six per minute, and the insensibility of the body was perfect. She recovered in four minutes, and ran out of the room.

It was a matter of some importance to ascertain if the narcotic principle of the fumes of the fungus would be given up to any fluid substance through which they might be passed. Yesterday, therefore, the fumes arising from the burning fungus, mixed with a large quantity of atmospheric air, were first driven through caustic potash, and then, in this diluted state, were passed, through alcohol, into a glass bell. A kitten placed under the bell soon became uneasy, at the end of an hour was taken out insensible, and recovered slowly.

I have intentionally destroyed a great many animals with the narcotic, in order to observe how it would produce death. The respirations fail in a gradual and progressive manner, until they cease altogether, and the breathing sounds are dry and loud. The pupil is usually dilated and fixed for several minutes previous to absolute death. The temperature of the body sinks slowly. The heart continues to beat quickly for some time after respiration has ceased. The blood is always red, and generally not readily coagulable; but in a cat which had breathed oxygen gas with the narcotic, it coagulated with great rapidity. The lungs are of a pale or pink colour, never congested, nor is there congestion of any other internal organ. The heart is empty of blood in most cases; and its contractions may be excited for long intervals of time. The respiratory muscles and the bowels may also be excited to motion for a long period after the body is laid open. In four kittens which I opened before respiration ceased, I saw the rhythmical action of the heart, and regular respiratory acts, for twenty-five minutes after the opening. The peristaltic action of the bowels remained for not less than forty minutes. In no case have I found the brain and spinal chord congested, or in any degree visibly affected. Cadaveric rigidity soon becomes very marked.

On the table before the Society there lies a full-grown dog, which has this day been destroyed by the fumes of the fungus. The body is laid open for the inspection of the Fellows. The animal was placed in a box filled with the impure fumes of the burning fungus. It was fairly narcotized in ten minutes. As I did not wish it to recover, I kept it in the vapour five minutes longer, and then found the respirations to be eleven per minute, and the heart-beats sixty; the pupils a little dilated, and fixed; the body warm. I continued to expose it to the action of the fumes for fifteen minutes more, when it was removed from the box. It was less warm, but there were still six respirations per minute, and the heart was beating steadily, with both sounds distinct. It was as insensible to pain as if really dead, and the body was flaccid. The pupil was fixed. Red blood flowed from the ear on puncture. I have not the shadow of a doubt that the animal would have recovered from this prolonged narcotism, had I kept it from the narcotic influence; for the respirations were increasing while I was taking the above observations. I returned it to the box; in five minutes more the respirations ceased, the

heart-beats continuing for some minutes later. The blood was fluid; the lungs, and all the other internal organs, were free from congestion, and the heart was pretty firmly contracted.

The fumes of the fungus, when clarified with caustic potash, and diluted pretty freely with atmosphere, are not unpleasant to breathe. On Thursday, I inhaled them myself in this form, for four minutes. They produced decided symptoms of stupor; the pulse was excited, and I was glad to sit down. These effects, however, passed off in three minutes, and I felt none the worse, except that the throat was somewhat irritated, and the voice a little hoarser.

My experiments would not have been complete, without having given some of the fungus itself to an animal as food. I have done so to two dogs, without effect. In one case, a large quantity of the fungus was cut up, and boiled in milk, and the milk was given to a dog. No narcotism or other effect followed. On a second occasion, a piece of the fungus (Ξ) was chopped up with beef, and given to a hungry dog. The animal swallowed the mess greedily, but showed no sign of injury. Withering states, on the authority of Marsigli, that the puff-ball is fried with salt in Italy, and is eaten as food; and I am told by Mr. Butler, the herbalist, in Covent Garden (from whom the fungus can be obtained), that he has eaten it himself when fried; and that Mr. Smith, the well known stationer in Long Acre, esteems it a great delicacy, and eats it regularly when in season (in autumn).

To sum up the results of these experiments: there is, it is evident, a principle in the fumes of the puff-ball capable of causing anaesthesia in animals. The physiological effects brought out by this anæsthetic are also very marked. In a liberal dose, it narcotises rapidly and effectually, without unpleasant symptoms; and the narcotic effect soon passes off, leaving the animal in perfect health. In diluted doses, it produces intoxication and convulsions; is longer in causing anaesthesia; sometimes excites cough and vomiting, and leaves the animal for a long time stupid and unwell. When it is carried to the extreme, the respirations cease before the beat of the heart. Indeed, in observing animals under influence of the narcotic, it is only necessary to watch the respiratory movements; if these remain, even though reduced to the lowest, the animal will certainly recover on removing it from the cause of the narcotism. In this respect the narcotic principle of the fungus resembles the Woorali poison.

Experiments with the fungus may be performed in various ways. If the impure smoke is to be used, it is only necessary to let it pass freely into a box, through a hole in the bottom. A large tin funnel fixed beneath the box in an inverted position will readily convey the smoke. The box having been filled with the smoke, the animal is placed in it, and the lid is laid lightly on. Narcotism will generally take place in eight or ten minutes, often sooner.

To clarify the fumes arising from the fungus, two small tin funnels are made to fit mouth to mouth, and the nozzle of one funnel is connected with a Wolff bottle containing a solution of caustic potash. Another tube, connected with the Wolff bottle, will convey the clarified fumes away. If, now, a piece of the fungus be placed in a burning state between the funnels, the smoke can either be drawn by the mouth from the exit tube of the bottle through the ordinary double valve apparatus for chloroform, or it can be driven over into a bell jar, by fixing the nozzle of a pair of bellows to the free end of the funnels, and blowing gently. The glass bell into which the vapour is received should be placed on a nicely fitting board, and the animal must be passed into the bell quickly, after it is charged with the narcotic vapour.

Some one, perhaps, will ask, What is the nature of the narcotic principle contained in the fumes of the fungus? Is it a product or an educt of combustion? On this subject I have no direct information. That several of the fungi possess a narcotic principle, has long been known; and some analysis has as yet thrown much light on the subject. In some countries fungi are used for making intoxicating potions. Our very distinguished countryman, Dr. ...

Taylor, in the second edition of his valuable *Manual of Medical Jurisprudence*, thus remarks on the fungi :

"Most of the narcotic irritant poisons, just considered, owe their deleterious effects to the presence of an alkaloidal principle similar to morphia, and susceptible of insulation by complex chemical processes. There is, however, considerable difficulty in extracting these alkaloids from the respective vegetables; and when extracted, the chemical differences among them, in respect to the action of tests, are so slight, as to be scarcely appreciable, even in the hands of a practised analyst."

The few conclusions, therefore, which it is in my power to offer with regard to this subject, are very insignificant; and are derived more from physiological observation than from chemical inquiries. However, they had better be stated.

I. The narcotic principle is given off freely during the combustion of the fungus; and, as it exists in the fumes produced, is highly volatile.

II. Combustion of the fungus in oxygen gas does not destroy the anæsthetic principle.

III. The anæsthetic principle is not quickly absorbed or destroyed, either by water, alcohol, or strong alkaline solutions.

I present these researches to the profession with great deference. I am aware that they are not so extensive as they ought to be, but they have cost me many weeks of incessant labour; and I put them forth as being calculated to lead to further inquiry into the narcotic effects of the fungi, by other and abler minds, rather than from an estimation of their own value. I have been desirous only to show that there is a principle in one of the fungi capable of producing narcotism in animals by inhalation. It remains to be seen, whether other plants of the same family possess similar powers; and whether a narcotic agent can be obtained from a fungus that shall admit of being employed in practice with no more trouble to the operator, and with less danger to the patient, than are entailed by the anæsthetic agents now in use. So important a subject is at least worthy of further investigation.*

Mortlake, May 1853.

CASE OF EXTREME LATERAL CURVATURE OF THE SPINE, OF MORE THAN FIFTEEN YEARS' DURATION.

By SAMUEL HARE, F.R.C.S.Eng.

CASE. SUMMARY. GREAT ACCOMPANYING DEFORMITY OF THE CHEST: THE HEART BEATING BETWEEN THE SECOND AND THIRD RIBS OF THE RIGHT SIDE: UNFAVOURABLE STATE OF THE GENERAL HEALTH: IMPROVEMENT UNDER TREATMENT: INCREASE OF THE BREATHING CAPACITY OF THE LUNGS.

Miss —, aged twenty-nine years, residing in the north of England, came under my care on April 15th, 1850.

History. She was born of very healthy parents, and her general health was stated to have been good during childhood, though she had suffered from some of the diseases incident to that period of life. When about twelve years of age, she suffered severely from an attack of scarlet fever, from which she was not expected to recover; and subsequently from inflammation in one ankle, from which period is dated the commencement of her future sufferings. The inflammation was accompanied with a great swelling of the part, and was so severe as to confine her more or less for six or seven months. She consequently became very weak and delicate, and suffered much from violent headaches, especially in the forehead.

It was when she was fourteen years of age that the curvature of the spine was first discovered, though it is probable that it had existed for some time previous. It was indeed supposed by herself and friends to have been caused by the improper or too constant use of the crutches, which she was obliged to use when she first began to walk, on gradually recovering from the affection of her ankle. The upper curve of the spine was noticed to be towards the right side, while a slighter one also existed towards the left, in the lumbar region. At that time, she was growing rapidly in height; and the progress of the deformity was equally rapid.

As the deformity advanced, her bodily weakness increased; she felt languid and tired, and complained of a dull, heavy pain in the spinal column, with a sensation of its being too weak to support the weight of the head and upper extremities. Instead of being extremely active, as she was wont to be, she became inanimate, and unable to go about without a tendency to faintness, and sometimes actually fainted: she had also a numbness both in the upper and lower extremities. She suffered likewise from nervous depression, painful sensibility and anxiety of mind, and a want of power to concentrate her attention upon anything, while her memory failed her very materially; her breathing became shorter and more difficult, attended with palpitation of the heart on using any exertion, or being subject to any excitement; her appetite sometimes failed her; at other times she feared to take food, from its causing severe pain afterwards, though, if she did not take it, she suffered from faintness and a sinking sensation.

The symptoms fluctuated from time to time, but, on the whole, got worse; the languor, lassitude, and weakness, continuing to increase: indeed, her symptoms were such as to cause considerable alarm and anxiety to her friends. Some time afterwards, and when the spinal deformity had made considerable progress, the heart was observed to beat to the right side of the sternum, which it continued to do up to the time of my seeing her. For two years prior to this time, her health became much worse, and for twelve months she had at times scarcely been able to walk at all, owing to her general weakness and the severe pain in her back, and her increasing deformity.

Condition on April 15th, 1850. She was rather tall, of good figure and conformation, with the exception of the spine and chest; of a sanguineo-nervous temperament, fair complexion, and brown hair; and of an habitually cheerful disposition. She complained of much lassitude and weakness, and of great fatigue on using the slightest exertion; and had fainted that morning on rising from her bed. She was thin, had very little colour in her cheeks, or even in her lips; and her skin was not so clear as natural. Her spirits were depressed; she was still subject to headaches, and slept very indifferently, having startings when in bed. She suffered much from the shortness in breathing, especially on using any exertion, or after taking food; and was much oppressed when in a close atmosphere.

The left side of the chest moved very little during respiration; the ribs on that side (in consequence of the deformity presently to be described) being so small, and so close to each other, as to render the intercostal spaces scarcely discoverable. She was free from cough and expectoration; palpitations were not constant, but were induced by any trifling exciting causes, and sometimes even without any assignable reason. In the morning, she was troubled with nausea, retchings, and sometimes with vomiting. Her appetite was at best capricious, and generally very bad, so that at times she had a loathing of food; her digestion was weak; and she often suffered from considerable epigastric pain, flushes of heat, and perspirations after her meals; while, at other times, she had a severe and distressing sinking sensation in the same region, and her feet were generally cold.

On examining the spine, I found an exceedingly extensive sigmoid curvature, which had caused so much general deformity of the trunk, that the level of the left shoulder (the acromion process) was no less than four and a half

* I return my deepest acknowledgments for many valuable suggestions, and much kind interest, to Drs. Willis, Cornack, Snow, and Crisp, to Mr. Thos. Taylor, and to Mr. Henry Hudson. I have also to thank my friends, Messrs. Leupner and Beresford, for the practical assistance they have rendered me in my experiments. And lastly, I am exceedingly grateful to the Fellows of the Medical Society for the kind manner in which they received this paper.

inches below that of the right one; while, on the left side, there was a space or hollow of two and three-quarter inches between the ribs and the arm. The convexity of the dorsal curve, which was the most striking, and included the whole of the dorsal vertebrae, was to the right side; while the curve in the cervical and lumbar regions projected to the left. The dorsal vertebrae, besides being curved to the right, were so twisted upon their own axes, that their spinous processes were directed to the left side; and a rather deep depression, corresponding to the groove between the spinous and the right transverse processes, marked, in the middle part of the dorsal region, the course of the vertebral column: in this manner, the right transverse processes projected more backward than the spinous ones. The ribs of the right side, especially above their angles, were so deformed as to project still further back than the transverse processes; and, by thus forming a prominent ridge, they tilted the scapula upwards and backwards to such an extent, that its internal border looked almost directly backwards: the projection of the eighth right rib about its angle was the greatest. While the ribs were thus prominent on the right side, those on the left were quite as much deformed, but in the opposite direction; for, at the lower part of the scapula, and below it, they were so depressed as to form quite a hollow, while the ribs themselves were felt to be in the most close contact with each other, to be exceedingly diminished in their diameter, and, instead of being flattened, they were rounded in shape, and in size were about equal to a swan-quill. In the upper part of the left interscapular region, the ribs were so deformed as to cause a somewhat circular prominence.

The anterior part of the chest presented proportionally as much deformity as the back; the ribs on the left side being prominent, and those on the right being flattened. Owing to the condition of the ribs (itself primarily dependent upon the deformity of the spine), the sternum was so far from occupying the mesial line, that its centre corresponded with the inner border of the left scapula; and, on standing exactly in front of the patient, the part of the chest seen to the left of the ensiform cartilage measured transversely only three and a half inches, while that seen to the right of it measured six and a half inches; and similar measurements, made at the level of the nipples, were, on the two sides of the midsternal line, four and a half and seven and a half inches respectively.

Owing to the flattening and depression, already alluded to, of the ribs of the left side posteriorly, the antero-posterior diameter of that side of the chest was very much diminished; indeed, in a patient of the same size as Miss —, I do not remember to have met with a chest in which the diameter from the nipple to the scapula was so small as two and three-quarter inches, which was the measurement in this case. As may well be supposed, when chests are so much deformed, it is not unusual to find the normal relation between the parietes and the position of the heart somewhat altered; but in this case the position of the heart was most remarkable, for it pulsated most distinctly between the second and third ribs of the right side; while, to the left of the sternum, its pulsation could not be detected. Beyond this displacement, there were no signs of disease in this organ; and the lungs, although their action was interfered with so as to cause much shortness of breath, seemed to be otherwise healthy. The right hip, as is always more or less the case in this kind of deformity, was depressed or flattened, and the left one was preternaturally prominent.

During the course of the disease, every pains had been taken to relieve her; and various plans of treatment, which had been suggested, were adopted. Thus, at one time she had been recommended to employ the old plan of carrying a weight (as a vessel of water, etc.) upon her head. She wore braces, which crossed her back, and passed round her body. At one time, she had a back-board, which was daily held by passing her hands backwards, above the shoulders; and at another, a back-board such as is used in the army. Other plans were employed, all supposed to have the power

of improving the muscular power of the left side; but, notwithstanding these, the disease continued to progress.

Having, in the history of several other somewhat similar cases of this disease which I have published, as well as in my work on *Curvatures of the Spine*, detailed the plan of treatment I adopt, it is unnecessary to enter at length into it on this occasion: suffice it to say, that exercises of any kind fail altogether to produce good effects in cases so advanced as the preceding; while I also consider that the recumbent position, when used *alone*, is capable of effecting but little. The recumbent position was used in this case; but it was combined with gentle extension, and with moderate pressure upon the projecting parts, in such a way, that its tendency was to restore them to their natural position. Great attention was also paid to the improvement of the general health by the use of appropriate remedies.

This was the plan which was commenced with; and the same, modified a little from time to time, according to circumstances or symptoms, was perseveringly pursued during the whole time that the patient was under my care. She had a course of alteratives with warm and mild purgatives, until the action of the digestive organs was improved; and the same remedies were afterwards prescribed, according as they appeared to be indicated, with occasional tonics.

It would be tedious to detail the notes taken from time to time of the progress of this case, extending over a period of more than twelve months; suffice it to say, that before she had been under treatment many days, she experienced, in consequence of having the weight of the head and shoulders removed from the diseased spine, and from the greater freedom with which she could expand her chest, very considerable relief as regarded the pain in her back, while the palpitations were less frequent, and the breathing more easy and comfortable. By the end of three months, her appetite had also very much increased, and she had almost ceased to feel any inconvenience after taking her food; while, with reference to her spine, she had already become somewhat straighter; the shoulders were flatter, and the chest less contracted; and the heart pulsated two inches lower down, though still to the right of the sternum. Her health continued to improve, and with it her spirits and her strength; while in the course of two or three months more she had entirely lost the pain in her back, which had troubled her so much and so long; the improvement in her form continuing at the same time to progress.

My notes, after she had been five months under treatment, were:—"She is decidedly better than she has been before, being free from ache or pain of any kind; she has good nights; her appetite and digestion are good, and she is able to take her food without any fear of suffering afterwards. She has lost all her faintness and weariness, and is free from palpitation, the heart having more nearly resumed its natural position. The inspirations are considerably deeper, and the breathing capacity of her lungs is much increased, being now fifteen inches more than in April last, and her spirits are excellent; her general appearance is much more healthy, her figure is considerably improved, and she is gaining strength, being able to take a little exercise without fatigue. The angle formed by the projecting ribs on the right side of the chest is less acute, and the hollow on the left has so much diminished, that while the distance from a line drawn vertically from the humeral end of the clavicle to the most receding point of the hollow, was at first three inches, it is now only two and one-eighth inches, showing a diminution of nearly an inch; the cartilages of the left false ribs project less; and the intercostal spaces of the right side are less marked, in consequence of her having become stouter and straighter."

The amelioration of all her symptoms continued to progress, so that, at the end of twelve months, and even before that time, she was able to walk about with ease and comfort; and when she left my care, after having been under treatment eighteen months, she was entirely free from the kind of pain, and from the lassitude which had hitherto been so distressing to her; while her strength had

tionally increased. Her complexion was much clearer; she had more colour; her appetite was good; she could take her food with a relish, and did not suffer from the dyspeptic symptoms. At times, she had a little faintness; but for many months she had not had the difficulty of breathing and palpitations from which she formerly suffered so much. There was still, of course, as must be expected in such a very serious case, some curvature of the spine, with consequent deformity of the ribs; but the figure was nevertheless erect, and the spine and ribs had each assumed a much more natural appearance; the hollow in the left side, and the projection on the right, having diminished very materially; and, as a necessary result of these changes, not only were the shoulders much flatter, but they had assumed very nearly the same level, so as to make in this respect also, especially when seen anteriorly, a most marked alteration and improvement in the figure.

In February 1852, a most favourable opportunity offering, I strongly advised her to take a sea-voyage; and she consequently crossed the Atlantic, and is now staying at one of the Colonial Islands. The reports which she has sent to myself and her friends are highly satisfactory, as she describes herself as being able to take considerable exercise both on foot and horseback; and there is reason to suppose she will remain some time in her present locality, from a letter I have lately received informing me of her marriage.

REMARKS. Although almost every case of spinal disease presents some points peculiar to itself, there are, on the other hand, certain features common to many of the examples of this affection, by which they become, naturally as well as conveniently, divided into certain classes or groups. Excluding from consideration examples of angular projection, dependent upon caries and absolute destruction of the vertebræ, there are three forms of curvature which are generally readily distinguishable, which are each usually accompanied by some peculiar symptoms, and which are dependent for the most part on distinct causes. These divisions constitute the classes of lateral curvature, excurvation, and incurvation; and of the first of these, the case under consideration presented a very marked example, whether we consider the extent of the deformity itself, or the severity of the general and local symptoms to which it gave rise. The progress of cases of lateral curvature after the disease has once manifested itself is by no means uniform; for the rapidity, or the reverse, with which the deformity advances, is dependent upon the time of life when it first appears, the state of the general health at the time and subsequently, the continuance of the causes which first induced it, the remedial measures employed, etc.: but, notwithstanding these circumstances, as the tendency of the deformity, unless efficient means be adopted, is to increase, the amount of the deformity is, to some extent, proportioned to the time it has existed. In this instance, both the duration of the disease and the degree of deformity were very great; the former having extended over a period of more than fifteen years, and the latter being such as not only very materially to shorten the trunk, but also to interfere much with the functions of the lungs and other important organs, and to cause considerable distress from dyspnoea and palpitations.

Each particular form of spinal distortion is accompanied with a condition of deformity of the ribs peculiar to itself, and different therefore from the deformity which they present in the other varieties of spinal disease. As incurvation affects almost exclusively the lumbar vertebræ, this is the kind of spinal disease in which the ribs are least affected; in excurvation, the ribs and their cartilages often lose their natural curve, become straighter near their anterior extremities, and join the sternum more or less at an acute angle, while the sternum itself may either project too much forwards or may be unnaturally forced inwards. In severe cases of angular projection and of lateral curvature, the ribs are always much more extensively and seriously implicated, though in very different ways. In the former, the ribs of each side, after curving forwards at about their angles, project downwards and somewhat towards the median line in

almost a straight direction, so that their extremities frequently fall quite within the iliac fossæ, and sometimes even rest upon the bodies of the pubic bones. The chest, therefore, in such cases presents a very flattened appearance laterally, and the anterior parts of the ribs are not only so close as to render the intercostal spaces very narrow, but the ribs are often actually in contact; nor do the changes stop here, for the ribs themselves undergo an interstitial alteration, by which they not only become much smaller, but they lose their flattened character and assume a more cylindrical shape. With the extremities of those ribs the cartilages form a very acute angle on proceeding to join the sternum, the lower end of which is usually very prominent. The condition of the ribs is widely different from and more complicated than this in lateral curvature; for while, in angular projection, the ribs of the two sides are tolerably symmetrical, they assume very opposite appearances on the two sides of the chest in lateral curvature. In this disease, the condition of the ribs is indeed dependent upon that of the spine; but their deformity adds very much to the general appearance of distortion. The foregoing case follows the very general—the almost universal—rule of the principal or dorsal curvature having its convexity directed towards the right; when this is the case, the right ribs become much bent backwards, at a point from two to three inches from their head, so as to form a hump, which tilts backwards the right scapula, while the left ribs become flattened posteriorly, and the scapula of that side is depressed; in a word, all the changes ensue which occurred in so marked a degree in this case, and which, therefore, have been detailed in the account given of it. It may, however, here be added, that while in angular projections the anterior part of all the ribs become attenuated, in lateral curvature this only takes place on the concave or left side of the thorax, in which also the intercostal spaces are much narrowed, while on the right side they are very considerably increased in size.

An interesting point, in reference to the above case, is the cause giving rise to it. This was believed by her friends, as well as herself, to be the use of a crutch for a considerable length of time; and, as the disease appeared during the time the crutch was in use, it is not improbable that this may have had something to do with it. At the same time it must be remembered that for such a cause to be effective in producing permanent deformity, the general health must have been in a very delicate state; for it is very uncommon to find permanent affection of the spine amongst the many who, from different causes, are obliged to have recourse to the aid of crutches; it is possible, however, that the first tendency to deformity may have been given in the way supposed, and, if so, the ordinary female dress, with its tight-lacing, would be a very powerful agent in increasing a disease which, in delicate persons, it is quite sufficient of itself to give rise to. On the mode in which this is effected, I have elsewhere very fully entered.

The disease, however, progressed for years, and scarcely could the deformity be called the worse part of the case; for, though in one point of view the primary affection, the secondary symptoms to which it gave rise were such as almost to embitter the patient's life, though they are only such as are frequently met with (often fortunately in a less degree) in similar instances of curvature.

That the functions of the heart should have been interfered with will be little wondered at when its position relatively to the parietes of the chest, on my first examining her, is taken into consideration; nor are palpitations, with frequent tendency to fainting, more than might be expected. Again, the surprise is as little that the patient should have been habitually subject to dyspnoea, when it is remembered that the antero-posterior diameter of one side of the chest from near the sternum to, and including the scapula, did not exceed two inches and three quarters; while the pressure to which the stomach and other organs were subjected, and the other circumstances of the case, were just such as would be likely to produce dyspepsia and its various concomitants.

But the patient had not been allowed thus to get worse without efforts being made to arrest the disease. Yet they had failed. And why? Because the remedies employed were not (and I believe such remedies cannot be made so) equal to cope with the requirements of such a case. General and local means must go hand in hand; the former to improve the general health, and the latter to rectify the deformity; but in a severe case, the last-mentioned indication can neither be effected by balancing a weight on the head, nor by gymnastics or other exercises, nor by endeavouring to throw certain muscles into action. In cases of angular projection, such plans are absolutely contra-indicated, and can only tend to aggravate the disease; while in cases of lateral curvature they fail, as in this instance, because, though the bones are not affected by caries, a certain alteration has taken place in their form, and it is necessary that, after the spine has been by gentle pressure according to the anatomical and pathological condition of the parts, and by slight extension, improved in form, it should be kept in that improved condition until, by the reparative powers of nature, such improvement has become consolidated. The reason why cases of very long standing cannot be improved to the same extent as more recent ones is, that in many of them ossific matter has been thrown out along the concavity of the spinal curve as the mode adopted by nature for the support of the weakened spine, and to prevent such further progress of the disease as might be incompatible with life. If the deposition of ossific matter take place to a great extent when the spinal column is in a deformed position, it necessarily tends to perpetuate the deformity; but the object to be aimed at is, in the manner I have alluded to, to restore the spine as much as possible to its natural shape, and to keep it there until, when the health improves and the reparative powers of nature ensue, the consolidation may take place while the spine is in a more natural position. Such, at least, are the views I entertain; and I feel that they are justified both by the success which in this case has attended treatment based on such principles, and by the result of very extensive experience which I have had in cases of a similar character.

9, Langham Place, London, May 11th, 1858.

BIBLIOGRAPHICAL NOTICES.

CONTINUOUS MOLECULAR CHANGES, MORE PARTICULARLY IN THEIR RELATION TO EPIDEMIC DISEASES; being the Oration delivered before the Medical Society of London. By JOHN SNOW, M.D., Vice-President of the Society. pp. 38. London: 1853.

ONE of the most valuable customs followed by that venerable and highly useful body, the Medical Society of London, is the annual election of a Fellow of the Society to deliver an oration on some subject connected with medical science.

Of all the orations that have been delivered before the Society—and we have read most of them with interest and instruction—we know not of one which upholds better the scientific character of the Society, than that to which we now direct attention.

As the subjects treated on by Dr. SNOW are all open to free discussion, and belong especially to a class of subjects in considering which many minds may fairly differ, it may be that, in reviewing his special opinions, we shall find reasons for questioning many of his arguments. Before descending to particulars, however, we must delineate in a few sentences the general character of the oration.

A distinguishing feature of this production is the abundance of the information it conveys. It is not a book made up of milk-and-water originality, with conceited omissions of other men's thoughts and labours; neither is it a mere patchwork display, containing a fact from Adams, a sentiment from Hecker, and notes from everybody, with nothing at all from the author except the stitches, and

those too small to be visible to the naked eye. No; it is just what a book should be; it is written out of the fulness of the writer's knowledge—is original sometimes—interesting in every part—honest always.

The oration embraces numerous questions, and indicates on the part of its author a large amount of general knowledge, which is, however, introduced on all occasions in such a modest, brief, and incidental manner, that the writer himself seems scarcely to be aware of its introduction. The attraction of matter, the combination of the elements that compose the atmosphere, the processes of combustion and putrefaction, the temporary suspension of what is called vital action, procreation, the origin and prevalence of communicable diseases, the origin of endemic diseases, the important subject of cleanliness, the effects of communicable diseases on the social condition of the human race, the value of quarantine, and the labours of Jenner, are the subjects on which the readers of this comprehensive pamphlet will find themselves feasted.

In the preface, Dr. SNOW enters on the knotty point, the meaning of the terms physical, chemical, and vital; and observes, that "it is especially desirable to have a general term to include what is understood by the words physical, chemical, and vital, in order to avoid the disputes respecting these two latter words, and the needless antagonism in which these words are sometimes placed towards each other." We quite agree with Dr. SNOW on this matter; but we wish that bold man joy of his task, who shall dare to fuse the two terms into one. Dr. SNOW himself seems inclined to offer a compromise. "All changes of composition," says he, "whether occurring in a test-tube or in the living brain, are properly included amongst chemical changes; and all that takes place in living structures has a right to be called vital, whether it differs from what occurs elsewhere, or not." But why this compromise? We confess ourselves unable to tell. If every change of composition in the body is chemical, then the word chemical is quite sufficient of itself to indicate the nature of the change; and the term vital is dead, and had better be buried where no one can find it: but if the changes in the composition of the body are something more than chemical, *i. e.*, vital, then let the word chemical be abandoned altogether in relation to bodily metamorphoses, and let us endeavour to discover what this peculiar, this vital action, is.

The oration opens with the consideration of the two kinds of attraction, "the attraction which the atoms of matter exert on each other at all distances, and the attraction which exists only at all insensible distances". These definitions of the attractive force are up to the present day orthodox; they cannot remain unquestioned much longer. "Attraction at insensible distances"—what can this mean? What is an insensible distance? In truth, there is no such a thing, there can be no such a thing, as an insensible distance. That between the atoms of bodies, or betwixt combinations of atoms, there may be spaces or distances which we cannot discern with the unaided eye, or even as yet with the microscope, we admit; but this is no proof that the distance alluded to is, in the abstract, insensible; the distance is only inappreciable to the visual organ, and to the imperfect optical instrument; it is perfectly understood by the mind; and the day may come when more than this will be arrived at. Moreover, if the attraction of very small bodies, or of the atoms of bodies, is to be called attraction at insensible distances, because of the minuteness of those atoms, then should we say, in like manner, that the power of attraction resident in bodies of stupendous magnitude, but so far removed from us in space as to be invisible even to the aided vision, is insensible attraction also, inasmuch as such attraction can only be inferred from other circumstances—cannot be seen. To be short, if the word distance conveys to the mind the idea of space, the space may be great or small, but space it is; and, as the mind can be brought by education to appreciate distances of any kind, the term "insensible distance" becomes a source of great obscurity and great error.

With an eye to the unity of the laws of nature, Dr.

Snow aptly illustrates the connexions that exist between the two forms of attraction which it is said there are. The whole of the important subject, the force of attraction, deserves, however, to be reconsidered by the philosophic world—a task for which our American brethren seem better prepared than ourselves.

In the second and third pages of the oration, there occurs a most singular contradiction—a contradiction which arises more from the curious nature of the experimental evidence that has been referred to, than from any inaccuracy or false reasoning on the part of the orator. He has been speaking of what is called “the balance of affinities” between portions or elements of matter, and he expresses a belief that the “idea that the nitrogen of the atmosphere manifests no attraction for the oxygen, is not quite correct; for,” he continues, “a red-hot iron wire is incapable of abstracting oxygen from the atmosphere, although it combines very briskly with that gas in the absence of nitrogen. A lighted candle, or a piece of ignited charcoal, has the power of abstracting only about one-fourth of the oxygen from a limited quantity of air, when the combustion ceases; whilst, in the absence of the nitrogen, it would consume nearly the whole of the oxygen. When animals are placed in an atmosphere made by mixing together equal parts of nitrogen gas and atmospheric air, they exhibit more distress, and die much sooner, than in an atmosphere of the same extent in which the oxygen and nitrogen are both reduced to one-half by the air-pump.”

From these experimental results, Dr. Snow infers, “that the nitrogen of the air exerts an influence over the combination of oxygen with other bodies. This depends chiefly on the affinity between the nitrogen and the oxygen—an affinity which is not great enough to cause their combination under ordinary circumstances, but is sufficient to counterbalance, to a certain extent, the affinity between oxygen and other bodies.”

Our readers will observe that these arguments tend to confirm the beautiful modern chemical hypothesis “of counter affinities”—an hypothesis which has been thought to account for the antiseptic properties possessed by many spirits, solutions, and gases; and, if Dr. Snow had left off at this point, and had proceeded to some other subject, there would have been no cause for surprise; but, singularly enough, he immediately brings forward another chemical experiment, which in a great degree clashes with those he has already referred to. It will be remembered that he stated, that a red-hot iron wire would not abstract oxygen from the atmosphere, because the nitrogen held the oxygen in check; but would oxidize in pure oxygen. He now shows, from no less an authority than Professor Graham, that, if another oxidizable substance be operated upon in the same manner, the results will be precisely reversed.

“Phosphorus is not acted on by pure oxygen at the ordinary temperature and pressure of the atmosphere; but, on diminishing the pressure, or adding a little nitrogen, the phosphorus begins to be oxidized. The reason of this probably is, that the attraction of the molecules of oxygen for each other prevents their union with the phosphorus, till this attraction is diminished by their increased distance.” (p. 4.)

Are not these experimental results very strange? Where does the contradiction lie? Does it arise from errors made in the experiments related, or in an erroneous endeavour to account for two opposite experimental facts on one and the same hypothesis? The error must be conveyed in one or other of these queries. For it is absurd to suppose that the nitrogen should play the double and contrary part of holding back oxygen from a burning wire, and of assisting the oxidation of phosphorus. And again, if the molecules of oxygen have such an attraction for each other that they will not unite with phosphorus, why do they not exhibit the same amount of attraction when brought into contact with ignited charcoal or a red-hot wire?

A captious critic might be inclined to dispute the first statement made by our orator, viz., that a red-hot iron wire will not oxidize in atmospheric air; for it is well known

that a red-hot wire will oxidize in the atmosphere to a certain extent. The correction, however, would not meet the difficulty, for the three succeeding experimental facts remain; and as they are most ably and correctly stated, Dr. Snow's position would not be altered, if the experiment with the wire were removed from the field of argument altogether. Instead, therefore, of criticising Dr. Snow for placing what seems to be a contradiction on a leaf of his book, we prefer to spend a few lines in an endeavour to show how the different experimental results to which we have called attention may be explained and reconciled.
